If the patient is too weak to use a sitz bath or an ordinary bathtub, cold compresses, bandages and packs will be my best substitutes. The packs and compresses must be changed before they became dry or hot, and should always be followed by a quick cold rub with a rough towel dipped in cold water.

In cases of great weakness or collapse, where the skin is cold and pale and the pulse weak, hot enemas of normal salt solution have a vivifying effect. In such cases a brisk cold rub should be given all over the body immediately after the hot enema. If suppression or retention of urine is caused by weakness and prostration the hot enemas are the best means of stimulating the urinary organs to renewed activity. The temperature of these hot enemas may range from 101 to 115 degrees F, according to the endurance of the patient. Warm enemas are usually followed by a more copious flow of the urine, indicating that they have a relaxing effect upon the kidneys and the bladder.

In cases of weakness, prostration and atrophy of the urinary organs, tonic neurotherapy treatment is always of great value.

2. The Treatment for Retention of Urine Due to Mechanical Obstruction. Obstruction to the passage of the urine may be caused by stones, large clots of blood, or by profuse excretion of mucous matter. In such cases the warm and even hot sitz bath may be of good service on account of their relaxing effect upon the tissues of the urinary organs. The passage of solid substance through the ureters and the urethra may be greatly facilitated by gentle downward stroking and manipulative treatment, also through relaxing neurotherapy (coccygeal) treatment. (Sec. XXVIII, No.17) For mechanical dilatation of the rectum, prostate and urethra, see "Orificial Treatment", Sec. XXVIII, Nos. 8-12.

3. Treatment for the Retention of Urine Due to Spastic Or Paralytic Conditions. This occurs frequently after the use of irritating diuretics and in the wake of hysteria and hypochondria. In all such cases lukewarm but cooling sitz baths will be beneficial. The most important treatment in such cues consists in inhibition of the nerve center by neurotherapy. In such cases, also, mechanical and manipulative dilatation of rectum and urethra as described under "Orificial Treatment", Sec. XXVIII, is indicated and often highly beneficial.

4. Treatment for Retention of Urine Due to Inactivity of the Kidneys. This condition may be the result of chronic nephritis or of a clogging of the kidneys through long continued food, drink and drug poisoning.
In order to cure this as well as all other chronic diseases the entire system must undergo a complete regeneration through natural living and treatment. But meanwhile the activity of the kidneys may be increased by the use of mild stimulants such as juniper berries eaten raw or in the form of tea. Kneipp's favorite prescription in such cases was as follows: Take three berries the first day, five the second, seven the third, and so on until the daily dose amounts to twenty one berries. Then the dose is reduced in the same way at the rate of two berries per day. After the course is completed a rest is taken for a few weeks and then the treatment is repeated if necessary.

5. Juniper Berry Tea. This is prepared in the following manner: Upon half a dozen or more macerated juniper berries pour half a cupful of boiling water. Let this draw, and sip while warm. A little honey or maple or brown sugar (unrefined) may be added if desired. Two such doses, or, in severe cases, three doses may be taken in twenty-four hours.

6. Asparagus Tea. The water in which fresh asparagus has been boiled for from ten to fifteen minutes is also a mild and harmless diuretic. It may be taken in half tea-cupful doses three or four times a day.

These special treatments for retention of urine should always be accompanied by the general natural treatment, which tends to overcome the constitutional diseases back of the local trouble.

SECTION XX

AIR, LIGHT AND SUN BATHS

What Is the Cause of Poor Skin Action?

Man is naturally an "air animal". He breathes with the pores of the skin as well as the lungs. However, the custom of hiding the body under dense, heavy clothing, thus excluding it from the life giving influence of air and light, together with the habit of warm bathing, has weakened and enervated the skin of the average individual until it has lost its tonicity and is no longer capable of fulfilling its natural functions.

The compact, almost air-tight layers of underwear and outer clothing made of cotton, wool, silk and leather prevent the ventilation of the skin and the escape of the morbid excretions of the body. Underwear, if worn at all, should be light and of porous weave, just close enough to absorb the perspiration but not close enough to prevent free escape of the poisonous exhalations of the skin. Thorough ventilation of the skin insures perfect evaporation of the perspiration, and this not only promotes cleanliness but has a wonderfully cooling effect upon the body in the heat of summer.

1. The skin is an organ of absorption as well as of
excretion; consequently the systemic poisons which are eliminated from the organism, if not removed by proper ventilation and bathing, are reabsorbed into the system just as the poisonous exhalations from the lungs are reinhaled and reabsorbed by people congregating in closed rooms or sleeping in unventilated bedrooms.

Who would think of keeping plants or animals continuously covered up, secluded from air and light? We know they would wither and waste away, and die before long.

Nevertheless, civilized human beings have for ages hidden their bodies most carefully from sun and air, which are so necessary to their well-being. Is it any wonder that the human cuticle has become withered, enervated and atrophied, that it has lost the power to perform its functions freely and efficiently? Undoubtedly, this has much to do with the prevalence of disease.

In the iris of the eye the atrophied condition of the skin is indicated by a heavy, dark rim, called the "scurf rim". It signifies that the skin has become anemic, the surface circulation sluggish and defective, and that the elimination of morbid matter and systemic poisons through the skin is handicapped and retarded. This, in turn, causes systemic poisoning and favor the development of all kinds of acute and chronic diseases.

2. The Importance of the Skin as an Organ of Elimination. Of late physiologists have claimed that the skin is not of great importance as an organ of elimination. Common experience and the diagnosis from the eye teach us differently. The black rim, seen more or less distinctly in the outer margin of the iris in the eyes of the majority of people, has been called the "scurf rim" because it was found that this dark rim appears in the iris after the suppression of "scurfy" and other forms of skin eruptions, and after the external or internal use of lotions, ointments and medicines containing mercury, zinc, iodine, arsenic or other poisons which suppress or destroy the life and activity of the skin.

Therefore, when we see in the iris of a person a heavy scurf rim, we can tell him at once: "Your cuticle is in a sluggish, atrophied condition, the surface circulation and elimination through the skin are defective and as a result of this there is a strong tendency to systemic poisoning; you take cold easily and suffer from chronic catarrhal conditions."

For the same reasons a heavy scurf rim indicates what is ordinarily called a "scrofulous condition", it stands for impoverished and vitiated blood. This certainly shows the great importance of the skin as an organ of elimination and the necessity of keeping it in the best possible condition. It explains why an atrophied skin has so much to do with the causation of disease and why, in the treatment of both acute and chronic ailments, exposure to air and cold water produce such wonderful results.

The favorite method of diagnosis employed by Father
Kneipp, the great Water Care apostle, was to examine the skin of his patients. If the "jacket", as he called it, was in fairly good condition he predicted a speedy recovery. If he found the "jacket" shriveled and dry, weakened and atrophied, he would shake his head and inform the patient that it would take much time and patience to restore him to health. He, as well as other pioneers of the Nature Cure movement, realized that elimination is the keynote in the treatment of acute and chronic diseases.

3. How to Take the Air bath. Everybody should take an air bath daily, for twenty minutes or longer, if possible. It may be advantageously combined with the morning cold rub and exercises as described under Sec. I.

Sixteen years ago we constructed the first open air bath on the roof of our Chicago Sanitarium. I predicted in the Nature Cure Magazine that the time would come when every up to date residence would have its air bath as well as its facilities for water bathing. This prediction is already being fulfilled. As a result of Nature Cure propaganda open air sleeping porches, sun parlors and air baths are rapidly increasing in popularity. All the hospitals built in the neighborhood of our Chicago Sanitarium have brick and iron enclosures on the roofs, similar to air bath construction. Their patients, however, still take the air and sun while heavily clothed and thus fail to receive the full benefit of air and sunlight.

A regularly constructed air bath is open above (without roof) and surrounded by shutter-like walls constructed of outward and downward sloping slats mortised in the upright posts so as to allow free passage of air and exclude any view of the interior from neighboring buildings. If surroundings permit, it is better to have the air bath on the ground for reasons explained later. This allows not only nude exposure to the air but also nude contact with the earth that, in itself, is highly beneficial.

An air bath on the level ground may be enclosed by shutter work, by solid board walls, or by canvas sheets. If possible, spend the hours of rest, and perform such daily tasks as may be feasible, in the air bath.

If an open air bath cannot be provided, expose the body to air and light in a room best located for the purpose. In the seclusion of this room remain nude as much as possible. But, after all, the air of a room cannot have the electromagnetic effect of moving currents of open air breezes, saturated with ozone and sunlight. Many naturists, having experienced the benefits of lying nude in bed, never again wear night clothing even though the bedroom be swept through the night by vigorous breezes. These are the people who have lost the habit of catching cold.

Only those who habitually practice air bathing can appreciate its soothing and tonic effect upon the millions of nerve endings all over the surface of the body. This explains the splendid results obtained by air, sun and cold water bathing in cases of nervousness, neurasthenia, and emotional
and mental disorders. Several of the largest sanitariums in Europe depend upon nothing but air bathing and rest for their curative effects in the treatment of nervous disorders.

Enjoying the luxury of an open air bath one need not envy the bathers at the seashore where police restrictions will not permit the appearance of women without shoes and stockings.

Even among the adherents of natural healing methods there are those who think that air and light baths should be taken out of doors in warm weather only, and in winter time only in well heated rooms.

This is a mistake. The effect of the air bath upon the organism is subject to the same law of action and reaction which governs the effect of water applications.

If the temperature of air or water is the same, or nearly the same, as that of the body no reaction takes place,—the conditions within the system remain the same. But if the temperature of air or water is considerably lower than the body temperature there will be a reaction.

In order to react against the chilling effect of cold air or water, the nerve centers which control the circulation send the blood to the surface in large quantities, flushing the skin with warm, red, arterial blood. The flow of the blood stream is greatly accelerated and the elimination of morbid matter on the surface of the body is correspondingly increased.

4. Sun Bathing. All the good effects of air bathing are intensified by the influence of sunlight. We will see that the effects of sunlight cannot be overestimated when we consider that without it life on this planet would be impossible. Everything that draws the breath of life depends for vital energy upon the life-giving rays of the sun.

Beginners, however, must be careful not to expose the body to intense heat and light for too long at a time. This might cause over-stimulation with its inevitable reaction, or serious burns. From ten to fifteen minutes may be sufficient to begin with. Dark skinned people, having more protective pigment, can stand more exposure than can light skinned people. As the skin bronzes or tans, exposure can be lengthened to twenty or thirty minutes, and gradually to several hours at a time. In the summer time, many of our patients spend all their leisure time in the air bath.

If possible the air bath should contain a spray so that a cold shower can be taken in warm weather while exposed to the air and sun. Allow the body to dry in the sun and air. The alternating influences of air, sunlight and water are as beneficial to the human body as to plant and animal life. Never miss an opportunity to take a nude rain bath.

People who are exceedingly sensitive to the effects of sunlight may at least temporarily wear a wrap of white gauze, or seek shelter in shady spots. In bright sunlight it is best to protect the head by a straw hat. Those who are subject to
excessive blood pressure to the brain should lay a towel wrung out of cold water over the head. For the treatment of sunburns see Sec. XLII, No.30.

5. Earth Magnetism. While in the air bath, if we lie eat on the earth on the back or stomach, we absorb the magnetism of Mother Earth. It is best to lie with the head towards the north in the direction of the magnetic currents of the earth. Such magnetic earth treatment is wonderfully soothing and refreshing. A good deal of the beneficial effect of barefoot walking is due to magnetic contact with the earth. In order to lie in harmony with the great magnetic earth currents, beds should always be placed with their heads to the north. Sensitives are strongly affected by lying crosswise of the currents; it causes restlessness and disturbed sleep.

In many cases of chronic constipation we have observed splendid results from lying on the stomach on the bare ground. The earth magnetism has a tonic effect upon the solar plexus and other nerve ganglia of the sympathetic. Good effects may be obtained while clothed, but nude contact with the earth is better.

6. Dry Brush Rub. While taking an air or sun bath rub the body thoroughly with a dry bristle brush, beginning with one not too stiff. The movements should be in one direction only. Sensitive persons prefer the stroking in the direction of the nerves, from the spinal cord outward. This dry rub not only stimulates skin action and circulation, but also removes dead cuticle and impurities from the surface of the body.

SECTION XXI

CORRECT BREATHING

The lungs are to the body what the bellows are to the fires of the forge. The more regularly and vigorously the air is forced through the bellows and through the lungs, the livelier burns the flame in the smithy and the fire of life in the body.

Practice deep, regular breathing systematically for one week and you will be surprised at the results. You will feel like a different person and your working capacity, both physically and mentally, will be immensely increased.

A plentiful supply of fresh air is more necessary than food and drink. We can live without food for weeks, without water for days, but without air only a few minutes.

1. The Process of Breathing. With every inhalation, air is sucked in through the windpipe or trachea which terminates in two tubes called bronchi one leading to the right lung, one to the left. The air is then distributed over the lungs through a network of minute tubes to the air cells, which are separated only by a thin membrane from equally fine and minute blood cells.
vessels forming another network of tubes.

The oxygen contained in the inhaled air passes freely through these membranes, is absorbed by the blood, carried to the heart and hence through the arteries and their branches to the different organs and tissues of the body, fanning the fires of life into brighter flame all along its course and burning up the waste products and poisons that have accumulated during the vital processes of digestion, assimilation and elimination.

After the blood has unloaded its supply of oxygen, it takes up the carbonic acid gas which is produced during the oxidation and combustion of waste matter, and carries it to the lungs where the poisonous gases are transferred to the air cells and expelled with the exhaled breath. This return trip of the blood to the lungs is made through another set of blood vessels, the veins, and the blood, dark with the sewage of the system, is now called "venous" blood.

In the linings the venous blood discharges its freight of excrementitious poisons and gases, and by coming in contact with fresh air and a new supply of oxygen, it is again transformed into bright, red arterial blood, pregnant with oxygen, the life sustaining element of the atmosphere.

This explains why normal, deep, regular breathing is all important to sustain life and as a means of cure. By proper breathing, which exercises and develops every part of the lungs, the capacity of the air cells is increased. This, as we have learned, means also an increased supply of life sustaining and health promoting oxygen to the tissues and organs of the body.

**2. Bad Effects of Shallow Breathing.** Very few people breathe correctly. Some, especially women with tight skirt-bands and corsets pressing upon their vital organs, use only the upper part of their lungs. Others breathe only with the lower part and with the diaphragm, leaving the upper structures of the lungs inactive and partially collapsed.

In those parts of the lungs that are not used slimy secretions accumulate and the tissues become devitalized. Thus a luxuriant soil is prepared for the tubercle bacillus, pneumococcus and other scavenger germs.

This habit of shallow breathing which does not allow the lungs to be thoroughly permeated with fresh air, accounts in a measure for the fact that one third of all deaths result from diseases of the lungs. To one individual perishing from food starvation thousands are dying from oxygen starvation.

Lung culture is more important than other branches of learning and training which require more time and a greater outlay of money and effort. In the natural regimen breathing exercises play an important part.

All important as are the elements of the air in the vital functions of the body, we take in something with the breath that is more essential to life than oxygen, and that is...
that which we call life force, which proceeds from the one central Source of life, intelligence and creative force and permeates all animate things in the sidereal universe, comes and goes, ebbs and flows with the breath. Every living thing inhales and exhales "the breath of life". This life force as it enters the organism is transmuted into the electro-magnetic energies and other life elements and vitamines.

3. General Directions. The effectiveness of breathing exercises and of all other kinds of corrective movements depends upon the mental attitude during the time of practice. Each motion should be accompanied by the conscious effort to make it produce a certain result. Much more can be accomplished with mental concentration, by keeping your mind on what you are doing, than by performing the exercises in an aimless, indifferent way.

Keep in the open air as much as possible, and at all events sleep with windows open.

If your occupation be sedentary, take advantage of every opportunity for walking out of doors.

While walking, breathe regularly and deeply, filling the lungs to their fullest capacity and also expelling as much air as possible at each exhalation. Undue strain should, of course, be avoided. This applies to all breathing exercises.

Do not breathe through the mouth. Nature intends that outer air shall reach the lungs by way of the nose, whose membranes are lined with fine hairs in order to "sift" the air, thus preventing foreign particles, dust and dirt, from irritating the mucous linings of the air tract and entering the delicate structures of the lungs. Also, the air is warmed and moistened before it reaches the lungs by its passage through the nose.

Let the exhalations take about double the time of the inhalations. This will be further explained in connection with rhythmical breathing.

Do not hold the breath between inhalations. Though frequently recommended by teachers of certain methods of breath culture, this practice is more harmful than beneficial.

4. The Proper Standing Position. Of great importance is the position assumed habitually by the body while standing and walking. Carelessness in this respect is not only unpleasant to the beholder, but its consequences are far reaching in their effects upon health and the well being of the organism.

On the other hand, a good carriage of the body aids in the development of muscles and tissues generally, and in the proper functioning of cells and organs in particular. With the weight of the body thrown upon the balls of the feet and the center of gravity well focused, the abdominal organs will stay in place and there will be no strain upon the ligaments that support them.
In assuming the proper standing position, stand with your back to the wall, touching it with heels, buttocks, shoulders and head. Now bend the head backward and push the upper body forward and away from the wall, still touching the wall with buttocks and heels. Straighten the head, keeping the chest in the forward position. Now walk away from the wall and endeavor to maintain this position while taking the breathing exercises and practicing the various arm movements.

Take this position as often as possible during the day, and try to maintain it as you go about your different tasks that must be performed while standing. Gradually this position will become second nature, and you will assume and maintain it gracefully and without effort.

When the body is in this position, the viscera are in their normal place. This aids the digestion materially and benefits indirectly the entire functional organism.

Persistent practice of the above will correct protruding abdomen and other defects due to faulty position and carriage of the body.

Breathing exercises are intended especially to develop greater lung capacity and to assist in forming the habit of breathing properly at all times. The different movements should be repeated from three to six times, according to endurance and the amount of time at disposal.

**Breathing exercises**

5. With hands at sides or on hips, inhale and exhale slowly and deeply, bringing the entire respiratory apparatus into active play.

6. (To expand the chest and increase the air capacity of the lungs)

   Jerk the shoulders **forward** in several separate movements, inhaling deeper at each forward jerk. Exhale slowly, bringing the shoulders back to the original position.

   Reverse the exercise, jerking the shoulders **backward** in similar manner while inhaling. Alternate the movements, forcing the shoulders first forward, then backward.

7. Stand erect, arms at sides. Inhale, raising the arms forward and upward until the palms touch above the head, at the same time rising on the toes as high as possible. Exhale, lowering the heels, bringing the hands downward in a wide circle until the palms touch the thighs.

8. Stand erect, hands on hips. Inhale slowly and deeply, raising the shoulders as high as possible, then, with a jerk, drop them as low as possible while exhaling.

9. Stand erect, hands at shoulders. Inhale, raising elbows sideways; exhale, bringing elbows down so as to strike the sides vigorously.
10. Inhale deeply, then exhale slowly. While exhaling clap the chest with the palms of the hands, covering the entire surface.

(These six exercises are essential and sufficient. The following tour may be practiced by those who are able to perform them and who have time and inclination to do so.)

11. Stand erect, hands to sides. Inhale slowly and deeply, at the same time bringing the hands, palms up, in front of the body to the height of the shoulders. Exhale, at the same time turning the palms downward and bringing the hands down in an outward circle.

12. (Fig. 7) Stand erect, the right arm raised upward, the left crossed behind the back. Lean far back, then bend forward and touch the floor with the right hand, without bending the knees, as far in front of the body as possible. Raise the body to original posture, reverse position of arms, and repeat the exercise. Inhale while leaning backward and changing position of arms, exhale while bending forward.

13. Position erect, feet well apart, both arms raised. Lean back, inhaling, then bend forward, exhaling, touching the floor with both hands between the legs as far back as possible.

14. Horizontal position, supporting the body on palms and toes. Swing the right hand upward and backward, flinging the body to the left side, resting on the left hand and the left foot. Return to original position, repeat the exercise, flinging the body to the right side. Inhale while swinging backward, exhale while returning to position.

**Diaphragmatic Breathing**

The diaphragm is a large, flat muscle, resembling the shape of an inverted saucer, which forms the division between the chest cavity and the abdominal cavity. By downward expansion it causes the lungs to expand like wise and to suck in the air. The pressure of air being greater on the outside of the body than within, it rushes in and fills the vacuum created by the descending diaphragm. As the diaphragm relaxes and returns to its original size and position, the air is expelled from the body.

15. To stimulate the action of the diaphragm, lie flat on floor or mattress, the head unsupported. Relax the muscles all over the body, then inhale deeply with the diaphragm only, raising the wall of the abdomen just below the ribs without elevating either the chest or the lower abdomen. Take about four seconds to inhale, then exhale in twice that length of time, contracting the abdomen below the ribs.
16. Internal Massage. (Fig. 8) Lie on your back on a bed or couch, knees raised. Relax thoroughly, exhale, and hold the breath after exhalation. While doing so, push the abdomen out and draw it in and up as far as possible each way. Repeat these movements as long as you can hold the breath without straining, then breathe deeply and regularly for several minutes, then repeat the massage movements.

Next to deep breathing, I consider this practice of greater value than any other physical exercise. It imparts to the intestines and other abdominal organs a "washboard" motion which acts as a powerful stimulant to all the organs in the abdominal cavity. Internal massage is especially beneficial in chronic constipation.

This exercise may be performed also while standing or walking. It should be practiced two or three times daily.

Breathing Exercises to Be Taken in Bed

17 With hands at side, inhale slowly and deeply, as directed in Exercise No.1, filling and emptying the lungs as much as possible, but without straining. Practice first lying on the back, then on each side.

18. (Use one, or two pound dumbbells.)

Position recumbent on back, arms extended sideways, dumbbells in hands. Raise the arms with elbows rigid, cross arms over the chest as far as possible, at the same time expelling the air from the lungs. Extend the arms to the sides, inhaling deeply and raising the chest.

19. Lie flat on the back, arms at sides. Grasping the dumbbells, extend the arms backward over the head, inhaling. Leave them in this position for a few seconds, then raise them straight above the chest, and lower them slowly to the original position. Exhale during the second half of this exercise.

As a variation, cross the arms in front of the body instead of bringing to sides.

20. Rhythmical Breathing. We are told in the books of the Ancient Wisdom Religion of India that the life force or prana enters through the nostrils; that in normal rhythmical breathing exhalation and inhalation take place through one nostril at a time—for about one hour through the right nostril and then for a like period through the left nostril.

The breath entering through the right nostril creates **positive** electromagnetic currents, which pass down the right
side of the spine, while the breath entering through the left nostril sends **negative** electromagnetic currents down the left side of the spine. These currents are transmitted by way of the nerve centers or ganglia of the sympathetic nervous system, which is situated along side the spinal column, to all parts of the body.

In the normal, rhythmical breath, exhalation takes about twice the time of inhalation. For instance, if inhalation require four seconds, exhalation, including a slight natural pause before the new inhalation, requires eight seconds.

The balancing of the electromagnetic energies in the system depends to a large extent upon this rhythmical breathing, hence the importance of deep, unobstructed, rhythmic exhalation and inhalation.

In order to establish the natural rhythm of the breath when it has been impaired through catarrhal affections, wrong habits of breathing or other causes, practice water sniffing (Sec. I, No.2), and the following exercise, not less than three times a day (preferably in the morning upon arising, at noon and at night). This will prove very beneficial in promoting normal breathing and creating the right balance between the positive and the negative electromagnetic energies in the organism.

**21. The Alternate Breath.** Exhale thoroughly, then close the right nostril and **inhale through the left**. After a slight pause change the position of the fingers and **expel the breath slowly through the right nostril.** Now **inhale through the right nostril** and, reversing the pressure upon the nostrils, **exhale through the left.**

Repeat this exercise from five to ten times, always allowing twice as much time for exhalation as for inhalation. That is, count three or four or six for inhalation and six, eight or twelve, respectively, for exhalation, according to your lung capacity. **Let your breaths be as deep and long as possible but avoid all strain.**

This exercise should always be performed before an open window or, better yet, in the open air, and the body should not be constricted and hampered by tight or heavy clothing.

Alternate breathing may be practiced standing, sitting or in the recumbent position. The spine should at all times be held straight and free. If taken at night the effect of this exercise will be to induce calm, restful sleep.

While practicing the alternate breath, fix your attention and concentrate your power of will upon what you are trying to accomplish. As you inhale through the right nostril will the magnetic currents to flow along the right side of the spine, and as you inhale through the left nostril consciously direct the currents to the left side.

There is more virtue in this exercise than one would suspect, considering its simplicity. It has been in practice
among the Yogi of India since time immemorial.

The wise men of India knew that with the breath they absorbed not only the physical elements of the air but life itself. They taught that this primary force of all forces, from which all energy is derived, ebbs and flows in rhythmical breath through the created universe. Every living thing is alive by virtue of and by partaking of this cosmic breath.

The more positive the demand, the greater the supply.

Therefore, while breathing deeply and rhythmically in harmony with the universal breath, will to open yourself more fully to the inflow of the life force from the source of all life in the innermost parts of your being.

This intimate connection of the individual soul with 'the great reservoir of life must exist. Without it life would be an impossibility.

22. Warning

While the alternate breathing exercises are very valuable for overcoming obstructions in the air passages, for establishing the habit of rhythmic breathing and for refining and accelerating the vibratory activities on the physical and spiritual planes of being, they must be practiced with great caution these, and other Yogi breathing exercises, are powerful means for developing abnormal psychical conditions. They are therefore especially dangerous to those who are already inclined to be physically and mentally negative and sensitive. Such persons must avoid all practices which tend to refine excessively the physical body and to develop prematurely and abnormally the sensory organs of the spiritual body. The most dangerous of these methods are long extended fasting, raw food diet (that is, a diet consisting of fruits, nuts, oils and raw vegetables and excluding the dairy products), Yogi breathing and "sitting in the silence"—that is, sitting in darkness, in seclusion or in company with others, while keeping the mind in a passive, receptive condition for extraneous impressions. These practices tend to develop very dangerous phases of abnormal and subjective psychism such as clairvoyance, clairaudience, mediumship and obsession.

SECTION XXII

PHILOSOPHY OF EXERCISE

Next to overeating, lack of exercise in the natural way is one of the leading causes of weakness and ill health. This is true because Nature in her wisdom so planned the mechanics and physiology of animal life that activity is essential to maintain normal conditions.

In all our preventive and curative work it is of the greatest
importance that we study carefully Nature's laws and Nature's methods and provide conditions as nearly as possible in harmony with them. In this way we may derive much help by studying the wonderful correspondences between vegetable, animal and human life based on the unit of life, the primitive single cell.

In the plant kingdom we find that activity or exercise of the unit cell is provided for by the wind, rain, and by changes in temperature and light. In the animal kingdom exercise is called forth by the search for food, by play and by aggressive and defensive warfare. In the human kingdom exists the same necessity for activity in search for food, provision for shelter, in play, and in defense against Nature's destructive forces and against animal and human enemies.

But man, loving leisure better than exertion and being a free moral agent, has followed the lines of least resistance. He enslaved the horse to draw his vehicles; invented railroad carriages, automobiles, bicycles and all kinds of labor saving machinery in order to gain speed and to avoid the necessity for physical exertion. The unnatural conditions of civilized society have overburdened some with hard physical labor and condemned others to indoor, sedentary occupations which compel almost complete physical inactivity.

Systematic, corrective exercises are needed to counterbalance both extremes.

Most persons who have to work hard physically are under the impression that they need not take special exercise. This, however, is a mistake. In nearly all kinds of physical labor only parts of the body are called into action, certain sets of muscles are exercised while others remain inactive. This favors unequal development which is injurious to the organism as a whole.

It is most necessary that the ill effects of such one sided activity be counteracted by exercise and movements that bring into active play all the different parts of the body, especially those that are neglected during the hours of work.

Hard gymnastic exercises such as weight lifting, boxing, wrestling and athletic feats which require great physical exertion are not conducive to normal development and longevity. On the contrary, steady, hard physical labor and severe, long continued gymnastic and athletic training over-stimulate and overdevelop the muscular structures of the body at the expense of the vital organs and of the brain and nervous system. They cause a "muscle bound" condition which means congestion of the blood in the fleshy parts and a deficiency in the vital organs, the brain and nervous system.

This tends to coarsen the body. The animal nature in time reveals itself in outward appearance in the coarsening of the features, in the disproportionate and distorted physique, and in stunted intellectual and esthetic development.

For these reasons Natural Therapeutic philosophy does not
favor strenuous physical and physiological exercise, but advises the lighter forms of physiological combined with psychological exercise.

SECTION XXIII

PHYSIOLOGY OF EXERCISE

Aside from breathing gymnastics, general exercises should be taken every day. In case of illness or deformity special corrective and curative exercises should be taken.

Physical exercise has effects upon the system similar to hydrotherapy, massage and neurotherapy. It stirs up the morbid accumulations in the tissues, stimulates the arterial and venous circulation, expands the lungs to their fullest capacity, thereby increasing the intake of oxygen, and most effectively promotes the elimination of waste and morbid materials through the skin, kidneys, bowels and the respiratory tract.

Furthermore, well adapted, systematic physical exercises tend to relax and soften contracted and hardened muscles and ligaments and other connective tissues and to tone up those tissues which are weakened and abnormally relaxed. Such exercises should always be prescribed during and after the correction of lesions of the spinal column and of other parts of the framework of the body.

Regular physical exercise means increased blood supply, improved nutrition and better drainage for all the vital organs of the body. By means of systematic exercise, combined with deep breathing, the liberation and distribution of electromagnetic energy in the system is also greatly prompted.

Increased physical activity means increased oxidation of fuel and of waste materials which in turn necessitates a greater intake of oxygen and compels deeper and more rhythmic breathing. This means not only a fuller intake of the elements of the air, but also a greater inflow of the life force itself. This primary force of all forces comes and goes, ebbs and flows in all living beings with inspiration and expiration.

The Hindu wise men call life the "breath of Brahman". Some use the expression "breath is life". To this I cannot subscribe. I would say breathing is the mechanical and physiological vehicle through which the life elements enter living forms. From this it follows that the deeper and more regular and more rhythmical the breathing, the greater the inflow of the life force into the living organism.

As it enters the body through the sympathetic nervous system it is transmuted on the physical plane into electromagnetic energy; on the vegetable plane into vitochemical energy; on the animal plane into mental and
emotional energy; and on the human plane, into the higher psychical activities. Each plane in addition to its higher properties retains the properties of the lower life elements. These life elements of natural philosophy are identical with the "newly discovered" vitamins of orthodox medical science.

Systematic physical exercise is an absolute necessity for brain workers and those following sedentary occupations. They not only need breathing gymnastics and corrective movements mornings and evenings, but should take regular daily walks no matter what the condition of the weather. Unless they do this faithfully their circulation will become sluggish and the organs of elimination inactive. The cells and tissues of the body will gradually become clogged with morbid encumbrances and this will inevitably lead to physical and mental deterioration.

**General Rules**

**a)** Weak persons and those suffering from malignant diseases such as cancer, tuberculosis, heart trouble, asthma, or front displacements and ruptures, or who are liable to apoplectic seizures, etc., should not take these or any other vigorous exercises except under the supervision of a competent physician.

**b)** At least twice a day all parts of the respiratory apparatus should be thoroughly exercised (Sec. XXI). Deep breathing should accompany every corrective movement, whether it be a special breathing exercise or not.

**c)** Begin the exercises each day with light movements and change gradually to more vigorous ones, then reverse the process, ending with light relaxing movements.

**d)** When beginning to take systematic exercise do not make the separate movements too vigorous or continue them too long. If any of them cause pain or considerable strain omit them until the body becomes stronger and more flexible. The muscular soreness often resulting from exercise at the beginning is, as a rule, of little consequence and soon disappears. The various movements should be practiced in spite of it, because that is the only way to relieve and overcome this condition.

**e)** Stop when you begin to feel tired.—Never overdo. You should feel refreshed and relaxed after exercising, not tired and shaky.

**f)** Do not take vigorous exercise of any kind within an hour and a half after eating, nor immediately before meals. It is a good plan to rest and relax thoroughly for about fifteen minutes before sitting down to the table.

**g)** Whenever practicable exercise out of doors. If indoors perform the movements near an open window or where there is a current of fresh air.

**h)** Exercise undressed, if possible, or in a regular gymnasium suit that gives free play to all the muscles. If
dressed, loosen all tight clothing. Women preferably should wear bloomers and loose blouse or smock. Of course no corsets should be worn, and but a single union undergarment of loosely knit light weight cotton. If a dress is worn it should be a simple, loose, one piece garment, short and full enough of skirt not to interfere with free leg movements. If shoes are worn they should be without heels, like tennis or gymnasium oxfords, wide enough to allow the toes to spread naturally when the weight is upon them.

i) Always relax physically and mentally before taking exercise.

j) Apparatus is not necessary to produce results. However, dumbbells, wands or Indian clubs may be used but they should not be too heavy. One pound dumbbells are sufficiently heavy in most cases. The exercises here described are intended for muscular control, flexibility, improvement of the circulation and increased activity of the vital functions rather than for mere animal strength.

In the following paragraphs we offer a selection of corrective movements graduated from the more simple to those requiring considerable agility and effort.

In practicing these exercises, it is best to alternate them, that is, to select, say, six or seven movements suited to individual conditions with a view to securing all-around general development and special practice for those parts and organs of the body that need extra attention. The time at your disposal will also have to be considered.

Practice these exercises daily for a week. For the following week select six different exercises, then six more for the third week and so on, supplementing the list here given as may be required by your particular needs. Then start all over again in a similar manner.

This is better than to do the same stunts every day. It promotes all round development of the body and keeps the interest from flagging.

**Corrective Gymnastics**

1. Raise the arms forward (at the same time beginning to inhale), upward above the head, and backward as far as possible, bending back the head and inhaling deeply. Now exhale slowly, at the same time lowering arms and head and bending the body downward until the fingers touch the toes. **Keep the knees straight.** Inhale again, raising arms upward and backward as before. Repeat from six to ten times.
For exercising the muscles between the ribs and the abdominal muscles in the back.

2. Inhale slowly and deeply, with arms at side. Now exhale and at the same time bend to the left as far as possible, raising the right arm straight above the head and keeping the left arm close to the side of the body. Assume the original position with a quick movement, at the same time inhaling. Exhale as before, bending to the right and raising the left arm. Repeat a number of times.

For making the chest flexible. Also excellent for the digestive organs.

3. (Figs. 9 a, b, c) Chest Stretcher. This exercise must be performed vigorously, the movements following one another in rapid succession.

Stand erect. Throw the arms backward so that the palms touch (striving to bring them higher with each repetition), at the same time rising on the toes and inhaling. Without pausing, throw the arms forward and across the chest, the right arm uppermost, striking the back with both hands on opposite sides, at the same time exhaling and lowering the toes. Throw the arms back immediately, touching palms, rising on toes and inhaling as before, then bring them forward and across the chest again, left arm uppermost. Repeat from ten to twenty times.

An excellent massage and vibratory movement for the lungs.

4. Exercises for filling out scrawny necks and hollow chests:

a) Stand erect. Without raising or lowering the chin and without bending the neck; push the head forward as far as possible, then relax. Repeat a number of times. Push the head straight back in similar manner, making an effort to push it farther back each time. Do not bend the neck. Repeat

b) Stand erect. Bend the head toward the right shoulder as far as possible, then relax. Do not rotate the head. Repeat.

Bend the head to the left shoulder in a similar manner, then alternate the two movements.

c) Stand erect. Bend the head forward as far as possible, making an effort to bring it down farther each time. Relax.
Bend the head **backward** as far as possible.

Bend the head, first forward, then **backward**. Repeat.

5. For exercising the muscles of the chest and the upper arm:

   Stand erect, elbows to sides, hands closed on chest, thumbs inward. Thrust out the arms vigorously and quickly, first straight ahead, then to the sides, then straight up, then straight downward, then backward. Repeat each movement a number of times, then alternate them, each time bringing back arms and hands to the original position quickly and forcefully.

   As a variation, raise the elbows sideways to shoulder height with fists on shoulders, then strike vigorously as before, opening the palms and stretching the fingers with each thrust. Repeat from ten to twenty times, or until tired.

6. Stand erect, hands on hips. Keeping the legs straight, rotate the trunk upon the hips, bending first forward, then to the right, then backward, then to the left. Repeat a number of times, then rotate in the opposite direction.

   Especially valuable to stir up a sluggish liver.

7. Lie flat on your back on a bed or, better still, a mat on the floor, hands under head. Without bending knees, raise the right leg as high as possible and lower it slowly. Repeat a number of times, then raise the other leg, then alternate. As the abdomen becomes stronger, raise both legs at once, keeping knees straight. **It is important that the legs be lowered slowly.**

   For exercising the abdominal muscles and strengthening the pelvic organs. This and the following exercise are especially valuable for remedying female troubles.

8. (Fig. 10) Lie flat on back, arms folded on chest. Place the feet under a chair or bed to keep them in position. Raise the body to a sitting posture, keeping knees, back and neck straight. Lower the body **slowly** to its original position. Repeat from five to ten times, according to strength.

**Supplementary Exercises**

9. Stride-stand position (feet about one half yard apart). Raise the arms sideways until even with the shoulders, then, without bending the back, rotate the trunk upon the hips, first to the right, then to the left.

   As a variation of this exercise, rotate from the waist only, keeping the hips motionless.

   An excellent massage for the internals organs.

10. See-saw motion:
Stride-stand position, arms raised sideways. Bend to the right until the hand touches the floor, left arm raised high. Resume original position. Repeat several times, then bend to the left side, then alternate.

11. Chopping exercise:

Stride-stand position. Clasp the hands above the left shoulder. Swing the arms downward and between the legs bending well forward. Return to position and repeat a number of times, then repeat with hands on right shoulder, then alternate.

12. Cradle rocks:

Clasp hands over head, elbows straight. Bend the trunk to the right and left side alternately and without pausing, a number of times.

13. Stand erect, feet together. Jump to the stride-stand position, at the same time raising arms sideways to shoulders, jump back to original position and lower arms. Repeat from ten to twenty times.

14. Lie flat on back, arms at side, legs straight. Raise both legs till they are they are at right angles with the body. From this position sway legs to the right and left side alternately.

15. Lie flat on back, arms extended over head. Swing arms and legs upward simultaneously, touching the toes with the hands in midair, balancing the body on the hip bones and lower part of spine. Return to original position and repeat.

This is a difficult and strenuous exercise, and should not be attempted at first.

16. (Fig. 11) Lie flat on stomach, hands under shoulders, palms downward, fingers turned inward, about six inches apart. This will give free play to the muscles of the chest. Raise the upper half of the body on the hands and arms as high as possible, keeping the body straight Return to position and repeat until slightly fatigued.

17. Same position as before. Raise the entire body on hands and toes, keeping arms and legs straight. Return to relaxed position and repeat the exercise.

As a variation, sway forward and backward while in the raised position.

18. Lie flat on stomach, arms extended in front. Fling the arms upward and raise the upper part of the body as high as possible, keeping the legs straight. Return to position and repeat but avoid excessive strain.

19. Same position as before, but hands on hips or clasped in
back. Raise upper part of body without assistance from hands or arms.

20. Rocking chair motion. Sit on a mat or bed, legs straight, arms at side. Recline so that the upper part of the body almost touches the mat, at the same time swinging the legs upward. Return to original position and repeat without any pause between the movements, rocking back and forth until slightly tired.

As you get stronger, clasp the hands behind the head.

As a variation, rock with the knees bent, hands clasped below them.

**Special Exercises for Reducing Flesh and Strengthening the Abdominal Organs**

21. Lie flat on stomach, heels and toes together, hands stretched out in front. Fling head and arms upward, at the same time raising the legs, knees straight. **Avoid straining.**

22. Same position, hands clasped on back, feet together. Roll from side to side.

23. Lie flat on back, seize a bar (bed rail or rung of chair) just behind the head. Keeping the feet close together, raise the legs **as high as possible**, then swing them from side to side. As a variation, swing legs in a circle without flexing the knees.

24. Same position. Raise and lower the legs without letting them touch the floor, keeping the knees straight.

25. Lie flat on the back, fold the hands loosely across the stomach. Raise and lower the upper body without quite touching the floor.

26. Stand erect, heels together, arms raised above the head. Bend forward and downward, endeavoring to place the palms of the hands on the floor in front of the body without flexing the knees. Return slowly to original position and repeat.

27. Stand erect, hands on hips. Keeping the body motionless from the hips downward, sway the upper part of the body from side to side and forward and backward, and in a circle to right and left.

28. Stand erect raise the arms above the head. Rotate the trunk upon the hips with extended arms, bending as far as possible in each direction, but avoiding undue strain. These are strenuous movements and should not be carried to excess or performed very long at a time.

**Physical Exercise for Invalids**

29. Persons who are very weak and unable to be on their feet for any length of time need not, for this reason, forego the benefits to be derived from systematic physical exercise.
A low chair, with straight or very slightly curved back and no arms, or a rocking chair of similar construction with a wedge placed under the rockers in such a manner as to keep the chair steady at a suitable angle, is well adapted to the practice of a number of corrective movements, such as rotating of hips and waist, forward and sideward bending of the trunk, the various arm and neck exercises, bending and twisting of feet and toes, and the internal massage. (Sec. XXI No.16.)

SECTION XXIV

PSYCHOLOGICAL EXERCISE

You may ever so often go through the ordinary forms of physical gymnastic exercises in a listless, inattentive way without deriving much benefit aside from a certain amount of development of the muscular structures. In order to derive from exercise genuine curative effects, mind and will must govern and vitalize the purely physical activity.

While it is true that the vital activities of the living organism continue independently of the individual consciousness, being under the control of the universal intelligence, we can learn to reinforce and to stimulate, or if necessary to relax and soothe the vital activities by the exercise of our own intelligence and power of will. This is proved by the following experiments: Let a physical culture class perform certain feats in weight lifting, instruct them to use all the physical energy at their disposal, and carefully record the results as to the amount of weight lifted, length of time required, etc. Then give to the class some brief explanation of the power of mind over matter and over the physical constituents of the body, and ask them to exert the power of their will to the uttermost while repeating the same feats. It will be found that the lifting power of the members of the class, thus reinforced by intellectual effort and the power of the will, can be increased from one third to one half.

I have seen a weak little woman under the control of a hypnotist display sufficient physical energy to overcome the concentrated efforts of four strong men to lift her from the floor or to move her from her place. I have seen her lift weights which could not be raised by two or three strong men. On another occasion I saw a weak boy carry the hypnotist, a man weighing over a hundred and seventy pounds, on his outstretched, unsupported arm.

The hypnotist in these Cases was not reinforcing his subjects by his own muscular strength. Their greatly increased physical strength and stamina was entirely due to the power of his will, acting on their subconscious minds through hypnotic control. I have explained the nature of this phenomenon more fully in Chapter XXX, Vol. I.

I do not mean by this to extol the practice of hypnotism, which is always destructive in its effect upon the mind and
soul of the subject as well as of the hypnotist, but these phenomena give us a marvelous demonstration of the power of concentrated will over matter and over the physical organism.

The cells and organs making up the great commonwealth of the human body should be under the complete control of mind and will. The cells, tissues and organs of the body are or should be physiologically and psychologically negative to the positive mind. In most people the normal polarity is reversed. Their minds and souls are negative and subjective to the constituents of the physical body. The slightest pain or discomfort fills their minds with fear and anxiety.

There is no better method to establish normal polarity,—the dominion of the conscious mind over the cells, tissues and organs of the body,—than systematic psychological exercise. Such exercise does not depend so much upon physical exertion as upon the action of mind and will on the nerves and nerve centers which control physical activity.

For instance, if the shutting and opening of the hands is intensified by mental effort and by the conscious exertion of the will, it will be of more benefit to the vitalizing of the muscular structures of the arm, as well as to the energizing of the brain and nerve centers concerned in the transaction, than the lifting of heavy weights which would unduly exercise the fleshy structures at the expense of the brain and nerve centers!

Psychological exercise becomes still more valuable for the strengthening of mental control over physical activity when the tensing of one part is accompanied by the relaxing of the companion part, for instance, when the tensing and bending of one arm is accompanied by simultaneous relaxation and unbending of the other arm. The same principle may be applied to all other companion parts of the body in so far as this is possible. The conscious tensing and relaxing exercises must be accompanied always by deep, rhythmic breathing.

From the foregoing it becomes apparent that psychological exercise is one of the most important methods in the treatment of physical disease; for anything and everything that helps to normalize and energize the functions of the body remove the underlying causes of disease.

**Effects of Psychological Exercises on Mental and Psychical Ailments**

In the treatment of mental and psychical disorders, psychological exercise is of special importance and of wonderful efficacy in bringing about improvement and cure where in the nature of the case that is at all possible. In all mental and psychical derangements one of the primary manifestations is a weakening of reason, will and self control and the gradual loss of coordination between mental and physical activities and the increasing loss of control of the
mind and will over the physical functions of the body.

For the reasons before explained it becomes evident that there can be no better way to strengthen will power and self-control, to reestablish coordination of mental and physical functions and thereby to strengthen the control of mind and will over the body and indirectly in other directions, than by systematic psychological exercises. It is, therefore, one of the most important features in our institution in the treatment of mental, emotional and psychical diseases.

**Natural Exercise**

Regular outdoor work sufficient to produce good perspiration, where one is in closest touch with Mother Nature, is the best of all exercise for human beings. The work itself should be constructive to the extent that it provides some of the necessities of human life and calls forth the best instincts of human nature. There is none better than the tilling of the soil for the production of vegetables, fruits and flowers.

Elimination through perspiration produced by vigorous outdoor work,—bareheaded and barefooted,—is best of all. Such natural activity should precede eating.

Numerous experiments have demonstrated that perspiration resulting from actual work or play is far more effective in the elimination of morbid matter from the human body than perspiration induced by steam baths, hot air, electric light baths or other artificial contrivances. It is also true that actual outdoor exercise in the shape of work or play produces much better results than exercise taken with special apparatus in heated buildings.

Next to the tilling of the soil, outdoor play is one of the best forms of exercise—such games as lawn tennis, golf, volley ball, football or baseball bring into activity the whole muscular system, provide the best possible exercise for the lungs, the heart and the vital organs, and at the same time call forth intense brain activity and concentration of mind by the competition and rivalry.

Next to outdoor sport, the best natural form or exercise is walking. To attain the best results walks should be taken not alone but in company with some congenial companion. Select some objective point and make the walk vigorous and rapid, the arms swinging free from the shoulders, the breathing deep and vigorous, the carriage of the body erect. Now and then take a "chest lift". This is done while walking. Hold the entire body erect, draw in a breath; after a few seconds, without exhaling, draw in another and after a further interval of a few seconds, still another. After the third inhalation vigorously expel all the air. The object of this is to inflate the chest to its fullest capacity.

Four or five miles are not too much for a good vigorous walk, although one or two miles a day may be all the average city dweller can afford. To get the best results from any form of exercise the clothing should be removed immediately.
afterward and a cold rub or cold sponge bath taken, followed by a brisk rub with a dry towel. This in turn should be followed by a few minutes rest or thorough relaxation in order to allow the system to resume its normal functions.

Since a large proportion of people who live in cities find it absolutely impossible in their regular daily life to take natural exercise in the shape of work, play or walking, they must have some substitute in the way of indoor exercise. Many people believe that the chief object of exercise is to develop large muscles and unusual strength, and for that purpose all kinds of special apparatus, weights and various other contrivances have been devised and sold at fancy prices.

Apparatus is entirely unnecessary for good physical development and for maintaining normal health. The leading authorities on physical culture agree that best results may be obtained by the simple exercises, resisting, tensing and relaxing, without the use of weights or special apparatus.

Exercise in order to produce best results must be regular. Set aside a certain time each day for this purpose and adhere to it. The body becomes accustomed to duties of this kind, performed at regular times each day. The entire reserve force of the organism is brought into play at these times and great benefit is derived not only from the physical effects but also from the concentration of mind and will on the work in hand, and this will gradually extend to all other forms of physical and mental occupations.

The following simple movements cover the whole range of psychological exercise. They may be modified or added to according to individual needs. The number of times each shall be done also depends upon individual conditions and requirements. Never hold the breath while exercising. At first continue the exercises until slight fatigue is felt. On an average fifteen to twenty times will be enough for each movement.

**As a final warning, remember that tensing in the sense used in these directions does not mean straining. Tensing to the point of straining and exhaustion would be decidedly harmful.**

**Psychological Exercises**

1. Stand erect, hands on chest, extend arms forward with a jerk, horizontally from the shoulders, tensing all muscles at the end of the movement. This should be done at the rate of about one movement per second.

2. Same as No. 1, except that the arms are extended downwards at the sides full length.

3. Strike out from the shoulder alternately with each arm, aiming at some imaginary point in front of you.

4. Clinch the fist tightly and strike a vigorous Mow from the left hip towards the right ear and across the shoulders. Alternate with the right. As before, end the movement by
tensing all muscles.

5. Stand erect, bring up the knees alternately as high as possible, stopping the movement by tensing all the muscles.

6. Stand erect, make a vigorous kick toward the front, first with the left and then with the right. Bring the leg to a sudden stop by tensing all the muscles. Extend the toes as far forward as possible when making the kick. The value of this exercise depends on the energy put into it. Do the same by kicking toward the rear.

7. (Fig. 12) Stand erect. Clinch the right fist, contract the arm, and bring the hand up under the right shoulder, raising the shoulder in the meantime as far as possible, and tensing all the muscles at the end of the stroke. Do this alternately with the left hand. While tensing one arm, relax the other.

8. (Figs. 13 a, b) Take an ordinary bath towel, grasp one end in the right hand, over the right shoulder, pass the left hand around below the waist and grasp the other end. Now raise the right arm to an extended position, resisting with the left arm. Change to the left arm over the shoulder and the right arm down to the hips. The resistance must be continuous from the starting of the movement to the return to the first position.

9. (Fig. 14) Grasp one end of a Turkish towel with the right hand raised to the shoulder, and the other end with the left hand raised to the shoulder, the towel passing behind the neck. Extend the right arm full length, resisting with the left
arm. Return to first position, continuing the resistance until the movement is ended. Repeat this exercise with the towel passing in front of the neck.

10. Stand erect, with both arms extended downward; tense the muscles of the upper forearm, hand extended, and raise the right hand to the shoulder, resisting the biceps muscles in the upper arm by the triceps muscles. Return to the original position, still tensing above muscles, at the same time raising the left arm to the shoulder.

11. Extend the arms out to the sides in horizontal position, tense all the muscles of the arms and shoulders, and bring the arms down close to the body. Repeat.

12. (Fig. 15) Raise the arms high above the shoulders and a little backward, tense all the muscles, and circle the arms outward and down in front of the body, crossing the hands in front of the abdomen, as shown in cut.

13. (Figs. 16 a, b) Raise the hands straight above the head, inhaling a full breath; gradually assume a squatting position as close to the floor as you can get, with the arms down between the knees, the head bent over, and the diaphragm muscle contracted. This is for the purpose of expelling all the air from the lungs.

14. Stand erect, with arms high over the shoulders. Bend over and touch the floor in front of the feet with the hands, the feet remaining flat on the floor, and the knees stiff. On returning to upright position tense the muscles in the small of the back.

15. (Fig. 17) Stand erect, raise the right arm fully extended, swing it up over the head, bend the body as far as possible straight to the left, keeping both feet solid upon the floor; then swing the body as far as possible to the right, raising the left arm and lowering the right. Keep both feet solidly on the floor. Tense the muscles of the arms while doing the exercise.

16. (Fig. 18) Stand erect, place the hands on the hips, the feet firmly on the floor, as shown in cut. Twist the body slowly to the right and then slowly to the left. Do not move the feet. Tense the muscles of the back and abdomen at the extreme end of each movement, and turn the head as far as possible in the direction of each movement.

17. Lie flat upon the floor or upon a bed, arms extended above the head. Raise the arms and the head and shoulders as far as possible from the floor contracting or tensing the muscles of the abdomen. Relax, and lie again upon the floor. Raise the hollow of the back from the floor, drawing the hips up towards the shoulders, contracting or tensing the muscles of the back.
18. (Fig. 19) Lie flat upon the floor, arms extended above head. Now raise both feet up over the chest, tensing muscles of the abdomen. This exercise may be made more strenuous by tensing the muscles of the legs and raising them up and down from five to ten times without touching the floor. Also extend the arms above the head and grasp an iron bedstead or any other apparatus available, with the hands; then raise the legs from the floor and gradually the hips, until the legs pass over and beyond the head. You may also swing the legs from one side to another or in circle.

19. Stand erect. Have the head well poised; bend it as far forward as possible till the chin touches the chest, and then as far backward as possible, without moving the body. Second, have the head well poised, and turn the head over to the right as far as possible, endeavor to touch the shoulder, then to the left as far as possible.

20. (Fig. 20) Have the head well poised and turn it to the right and left alternately without moving the body. While doing this exercise tense the muscles of the neck, and if desired, you may resist the neck movements by either hand.

21. Stand erect, heels close together, raise the body on the toes as high as possible. Resume normal position, lift the feet, the heels remaining on the floor. Repeat this with the feet ten inches apart. Repeat again with the feet eighteen inches apart.

22. For cold feet sit upon a box or bench or chair high enough so that the feet swing clear of the floor; work the ankle joints vigorously, raising the ball of the foot as far as possible toward the knee, and then lowering it as far as possible. Do this for about one minute to begin with, and gradually increase to from two to five minutes. This will start the circulation of the blood in the feet.

23. (Fig. 21) Raise arms horizontally at sides, palms up. Contract right arm bringing fist toward head and turning the face toward it simultaneously, resisting biceps muscle with triceps muscle, left arm extended outward relaxed-reverse (see cut).
24. (Figs. 22 a, b) Hands on chest. Raise elbows up as high as possible and down again. Inhale while raising. Exhale while lowering. Then reverse.

SECTION XXV

NATURAL TREATMENT FOR THE EYES

The health of the eyes, as well as that of all other parts of the body, depends upon perfect nutrition, drainage and nerve supply. Diseases of the eyes, unless caused by external injury, excessive strain under inadequate light or by exposure to brilliant light, are due to constitutional conditions.

The sensory organs do not weaken and become diseased unless there is something wrong with the three primary life requirements-nutrition, drainage and nerve supply. Most of the work of eye specialists, as long as they do not treat constitutional causes, is, therefore, not curative but symptomatic and suppressive.

The delicate mechanism of the eye becomes easily obstructed with pathogenic encumbrances which cause interference with the free circulation of blood, lymph and nerve currents. Cataract is nothing but an infiltration of the lens with pathogenic materials.

The same uric acid, oxalic acid and crystallloid earthy substances that form deposits in the rheumatic joints also accumulate in the lenses of the eyes and cause them to become milky and impervious to light. All the various forms of inflammations of the eye, if not caused by injury from without are due to pathogenic obstruction, like all other forms of inflammation in the body.

The natural treatment of the eyes, therefore, aims to remove pathogenic encumbrances and to adjust the mechanical lesions or abnormalities in such a way as to establish perfect nutrition, drainage and nerve supply. This accomplished, ailments of the eyes become a thing of the past and good sight may be maintained to the end of life.

From the foregoing it follows that the treatment of the eyes must begin in the first place with the natural treatment of the body as a whole. This is accomplished by faithful adherence to the regimen for wholesome living outlined in Sec. I.

This, with neurotherapy, has in many instances sufficed to cure serious chronic ailments of the eyes. Many people have come to us for the treatment of chronic constitutional disease, not expecting their weakened eyes to be especially benefited, believing this to be impossible. They were most pleasantly surprised when they found that together with constitutional improvement came also much better eyesight and keener hearing.
But hand in hand with constitutional regeneration should also go special treatment of the eyes themselves. This consists in an adaptation of several important natural methods of treatment; namely, hydrotherapy, eye gymnastics and massage. In many cases it may be necessary to supplement this combination by neurotherapy in order to correct mechanical lesion and abnormalities in the spinal column and nerve tissues which may interfere with the blood and nerve supply of the eyes and with adequate drainage.

1. Water Treatment. For the eye bath the temperature of the water should be as cold as the sensitive eyeball can stand, but not cold enough to cause serious discomfort. A few grains of salt may be added to make the water slightly saline.

   a) Submerge forehead and eyes in a basin of water, open and close the lids under water from six to eight times. Repeat a few times.

   b) Fill a glass or aluminum eyecup (which can be bought in any drug store or department store) with water, bend the head forward and press the cup securely against the eye; then bend backward and open and shut the lid a number of times.

   c) Bend over a stream of water running from a faucet or over a large dish containing cold water of natural temperature as it comes from the hydrant or well; then scoop up the water in the hollow of the hands and throw it into the open eyes, at the same time move the eyeballs sideways in circular or up and down motion. This is done in order to permit the water to reach all parts of the eyeball equally.

   The cold bathing is continued until the eyes cease smarting and perfect reaction is established. This may require about a minute.

2. Massage and Vibratory Treatment. We have learned in other parts of these volumes that massage has very much the same effect upon the circulation of the blood, lymph and nerve currents as hydropathic treatment. It stirs up the pathogenic deposits in the tissues and actually squeezes them into the lymphatic and venous circulation, thus allowing a free inflow of the red arterial blood with its freight of life sustaining oxygen and other elements of nutrition. Like the cold water, it stimulates the flow of the sluggish, pathogen laden lymph and venous blood towards the heart and the organs of elimination.

   Another very important effect of the massage of the eyes lies in the fact that it makes the eyeball more elastic and resilient, thereby correcting abnormal depressions and inequalities of the surface; in other words, it rounds the eyeball more perfectly. This is a simple and natural way of curing astigmatism, which the oculist tries to overcome by specially ground lenses. It is easily to be seen which of these methods is the more natural and rational. The one endeavors to overcome a symptom; the other removes the cause and actually corrects the abnormal condition.
Both massage and hydropathic treatment, aside from their mechanical effects upon the circulation, nutrition and drainage, also arouse and stimulate the latent electromagnetic energy. This, together with a more liberal supply of alkaline mineral elements in food and drink, raises the positivity of the organism, which means greater vitality and recuperating power. The best massage movements adapted for the eye treatment are the following:

3. Massage Movements. (a) Kneading. In order to execute this movement, press the eyeballs out of their sockets with the tip of one or two fingers of each hand. Continue this until the eyeballs have received a thorough kneading, as far back in the sockets as possible. You need not be afraid of injuring the eyes by this treatment unless you exert undue or excessive force.

b) Vibrating. Vibrate the eyeball all over its surface as far as you can reach it, first with one, then with two and lastly with three fingers—the thumb, forefinger and middle finger brought to a point. The movement is executed by a quick vibratory motion of the hand in the wrist joint. It may require some practice before perfect vibratory motion is attained, but when once acquired it is very beneficial for the purposes described in this treatise.

After thoroughly vibrating the eyeball for about a minute, finish with the stroking movements.

c) Stroking. This movement is executed by stroking the eyeball, first gently, then gradually more and more strongly, with one and later two finger tips. The stroking proceeds over the upper and lower lids from the inner corners of the eyes outward; then reverse and stroke from the outer corner of the eye in a half circular motion to the inner corner. These movements also are repeated from a dozen to two dozen times, according to the endurance and time available.

The stroking is applied first gently and with gradually increasing pressure until the eyeball has become seemingly insensible. As before stated, none of these treatments, if executed with a little care and common sense, can possibly inflict any injury. Although the mechanism of the eye is very complicated and highly sensitive, it is at the same time very tough and resilient. Cures of serious eye troubles which are little short of miraculous have been effected by this simple treatment. If faithfully applied at least twice a day, or, if possible, in conjunction with the general regimen for natural living and with neurotherapy, it will do away in a great many cases with the necessity for the wearing of glasses, and will preserve excellent eyesight under strenuous usage, even to extreme old age.

4. Eye Gymnastics. After the eyes have recovered sufficiently from the cold bathing, practice eye gymnastics. Stand erect, or if too weak assume a comfortable relaxed position in a chair, then move the eyes upwards and downwards, as far as the mobility of the eyeballs will permit, along an imaginary vertical line on the wall opposite you.
Repeat this from twelve to twenty-four times.

Then in like manner move the eyeballs as far as you can force them from right to left and left to right on an imaginary horizontal line in front of you on a level with your eyes. Move the eyeballs in similar manner diagonally from the highest point on the fight to the lowest point on the left, and then reverse.

Finally roll the eyeballs in circular motion from fight to left and then from left to right. Each one of these movements should be repeated from twelve to twenty-four times, according to the time at your disposal.

The special value of these eye exercises lies in the fact that the movements of the eyeball are regulated by four sets of muscle which pull the eyeball upward; downward, to the right and to the left.

The ordinary use of the eyes in certain occupations such as reading, playing the piano, etc., may exercise the eye muscles unequally and thus overwork and strain some of them while others are weakened through lack of exercise. In time this is bound to result in unequal development of these muscles and in one-sided strain. This in turn results in unequal focusing of the eyes, which seriously interferes with normal vision. This is usually corrected by fitting lenses specially adapted for this purpose, but it is obvious that the better adjustment consists in equalizing the strength of the four muscles which control the movements of the eyeball.

SECTION XXVI

CONSTIPATION

Constipation is characterized by sluggish action of the bowels. For some reason the evacuation of waste matter from the colon has become difficult. Normally an individual should have a copious movement of the bowels once in twenty-four hours-twice is better.

Constipation has become so common among people of civilized countries that this has been called "the age of constipation". At least three-fourths of the chronic patients that come to us for treatment, suffer from chronic constipation in its worst forms. Many of them tell us that they have not had a natural movement of the bowels for many years. This alone is sufficient to show that the ordinary methods of living and of treating human ailments are faulty and inadequate.

While itself a form of disease, constipation becomes in turn one of the primary causes of other constitutional diseases. Inactivity of the eliminating organs, the skin, kidneys and bowels causes retention of waste and morbid matter which results in systemic poisoning or auto-intoxication. Any system of treatment which cannot restore the normal activity of the organs of depuration cannot accomplish anything else.
The medical treatment of constipation, consisting largely in
the administration of laxatives and cathartics, gives only
temporary relief and tends to benumb and paralyze the
intestines more completely. This has been explained in
Volume I, Chapter VII. All laxatives and purgatives are
poisonous to the system or they would not produce their
peculiar drastic effects. They do not act upon the system but
the system acts upon the drugs. Being poisons, the organism
tries to expel these enemies to health and life by copious
excretions from the liver and from the walls of the intestines.
This eventually produces an evacuation of the contents of the
bowels, but every time such violent artificial stimulation is
resorted to the liver and the membranous linings of the
intestinal tract and the nerves which supply them, become
more benumbed and inactive. This progressive atrophy is
revealed in the iris by the darkening of liver and digestive
areas, located directly around the pupil.

As constipation becomes more stubborn, this region
becomes darker, with brown discolorations, turning gradually
black in places. In cases of serious atrophy of the membranes,
the intestinal area presents a uniform black appearance. We
find this frequently in people who have habitually used
calamel or have taken other mercurial treatment. Quinin and
the derivatives of opium also have a very paralyzing effect
upon the digestive tract. The acute catarrhal conditions
characterized by frequent purging are indicated in the iris by
white signs in the intestinal area.

Other causes of constipation are (1) congestion of the liver,
causing deficient or abnormal secretion of bile; (2)
interference with the blood supply of the intestines, causing
insufficient secretion of mucous, thus reducing lubrication
and causing excessive dryness of fecal matter. (3) interference
with the motor nerve supply to the muscular walls of the
intestines (partial paralysis) thus reducing the peristaltic
action of the intestines, which in turn causes stagnation and
fermentation of fecal matter; (4) spasm of the sphincter
muscles of the rectum, inhibiting the act of evacuation; (5)
mechanical pressure upon the intestines by new growths,
tumors or adhesions.

Chronic constipation is usually preceded by periods of
diarrhea. Hyperactivity, due to excessive stimulation, is
always followed by corresponding weakness and gradual
atrophy. The ordinary high protein and starchy diet produces,
as we have learned, excessive amounts of poisonous acids,
ptomains, alkaloids, xanthins (collectively called pathogen).
These morbid materials are powerful stimulants. Their effects
are frequently mistaken for increased vigor, as in the case of
meat and coffee poisons. They over irritate and over stimulate
the liver and the membranes of the intestines, causing an
excessive flow of secretions and increased peristaltic action of
the bowels. This results at times, when the digestive organs
become clogged with pathogenic matter, in periodic diarrheas.
This is the rule during infancy and youth. Gradually, however,
continual irritation and over stimulation, with the attendant
purging, changes, in accordance with the laws of action and
reaction, into the opposite condition of chronic constipation
which is aggravated and made more stubborn by the use of laxatives and cathartics.

Constant clogging of the liver with the morbid by products of a high protein and starchy diet leaves that organ in a congested and inactive condition. This interferes with the secretion of bile which in turn causes dryness of the contents of the bowels and deprives them of the lubricants necessary for easy evacuation of the feces.

Continual over irritation and over stimulation resulting from pathogenic poisoning also benumbs and paralyzes the motor nerves which supply the muscular walls of the intestines, resulting in partial paralysis and diminished peristaltic action. This is aggravated by the continual intake of food materials deficient in cellulose and woody fiber, such as white flour products and polished rice. The hulls of cereals, which act as natural stimulants to the peristaltic action of the bowels, are removed in the modern "refining" milling process. The particles of hull in whole grain meals serve to keep the starchy parts of the cereals from coagulating into lumpy masses and thus facilitate the penetration of the digestive juices into the starchy mass. It is for this reason that the followers of nature cure have always advocated the use of whole grain foods and the liberal consumption of fruits and vegetables whose fibrous waste serves as scouring material for the intestinal tract and as a natural stimulant for peristaltic action.

Spasm of the sphincter muscles of the anus, or spasm of the rectum, is usually caused by long continued over irritation with systemic poison or by the paralyzing effect of drug poisons. Many such cases I have traced back to suppression of gonorrhea or hemorrhoids. Such chronic paralysis and inhibition must be overcome through general constitutional treatment, cold tonic sitz baths and tonic manipulative treatment.

Mechanical pressure upon and resulting obstruction of the intestines caused by tumors, new growths or adhesions must be removed through absorption of the abnormal growths and adhesions by natural living and treatment, with strict vegetarian diet and occasional fasting periods. Hydrotherapy and manipulative treatment are necessary to achieve satisfactory results. Such deep seated chronic conditions, therefore, require systematic institutional treatment.

Mental and emotional conditions exert a powerful influence upon the alimentary tract. Certain emotions have a benumbing, others a stimulating effect upon the secretions and the peristaltic action of the bowels. A few days ago I read about certain experiments made with living animals. X-ray pictures were taken of a healthy cat whose peristaltic movements were normally active. The animal was suddenly confronted with an angry dog barking at her fiercely. Instantly, as the hair on her body and her tail went up as the result of sudden fright and anger, the peristaltic action of the stomach and bowels ceased entirely and did not revive until the animal had thoroughly recovered from its emotional
excitement. It also has been proved by experiments on living animals that sudden emotional excitement stops the secretion of the gastric and pancreatic juices. The nature and treatment of nervous, mental and emotional disorders is fully discussed in Section XXIX, No.3, p.258.

The most remarkable case of constipation that has come under my observation was that of a woman suffering from a severe attack of appendicitis and general peritonitis. She had been under Christian Science treatment for six days, her condition in the meantime becoming more aggravated until she was in a dying condition. Cold water compresses and manipulative treatment relieved her intense suffering almost instantly. We tried to empty the colon by repeated flushings, but without success. The bowels did not move for twenty-eight days, then they moved naturally without artificial aid. From that time on the patient made a rapid and perfect recovery.

During the four weeks she had received no food whatsoever. The usual hydropathic and manipulative treatment controlled the fever and gradually revived the peristaltic action of the paralyzed intestines. Eating at any time during the period of constipation would have meant sure death.

As before stated, habitual constipation means not only deficient elimination but also reabsorption of toxins from the putrefying materials in the intestinal canal, especially in the descending colon and rectum. Appendicitis is practically always preceded by an inactive, atrophic condition of the intestines, which favors the accumulation of fecal matter in the cecum and descending colon, which in turn leads to inflammation of the cecum and appendix.

The causes and treatment of appendicitis have been fully described in Volume 1, Chapter XII.

In the urine of people suffering from chronic constipation we usually find considerable amounts of indican, a poisonous ptomain which forms in putrefactive processes in the intestines. This is absorbed into the general circulation and partially eliminated through the kidneys. In like manner many other alkaloids of putrefaction are absorbed from the stagnant, putrefying materials in the sluggish intestines, causing headache, nervousness, muscular fatigue, sluggish mentality and many other ailments. Arteriosclerosis, Bright's disease, diabetes and premature old age are caused or aggravated by the continual absorption of intestinal toxins.

Post mortem examinations often show the lining membranes of the colon, cecum and of certain parts of the small intestines covered with adhesive, puttylike fecal materials. Such a clogged condition of the intestinal membranes interferes with assimilation 'as well as with elimination. This leaves the blood in an impoverished condition and overcharged with systemic poisons, causing on the one hand, nerve starvation and, on the other hand, nerve poisoning.
This condition of the intestines is revealed in the iris by a darkening and brown discoloration of the digestive area and by the lymphatic rosary. Frequently when I tell patients that their intestinal tract is in a clogged and atrophic condition, they seem surprised, saying there is nothing the matter with their bowels because they move regularly. This, however, is not evidence that the bowels are in a normal condition or that the individual is free from intestinal autointoxication. As before explained the intestines, particularly the colon down as far as the sigmoid flexure, may be encrusted with adhesive fecal matter, leaving a clear way in the center for the passage of recently formed waste products. In such cases it is necessary to resort to measures which are somewhat drastic in order to quickly and thoroughly cleanse the colon.

1. **Treatment.** It must be understood that the first requisite in the treatment of any disorder, and especially of constipation, is a change of diet. The diet for an individual suffering with constipation must be of such a nature as to preclude the possibility of the formation of toxins and at the same time to assist in the removal of morbid accumulations from the alimentary tract. Finally, the diet must contain the positive mineral elements necessary to neutralize the negative pathogenic substances in the circulation and in the tissues of the body.

   Meat, coffee, fermented cheese, fried foods, white bread, pastry and all other white flour products must be strictly avoided, as also the habitual use of condiments, spices and white sugar.

   A raw food diet, rich in fruit and vegetables, low in proteins, starches and fats; is best adapted to quickly bring about the desired results. All kinds of fruit, fruit juices and leafy, juicy vegetables are of the utmost value, but a mixture of many at one meal is not advisable. Salads, consisting of lettuce or other leafy vegetables, and raw carrots, turnips, parsnips, celery, young onions and radishes, with a dressing of lemon juice and olive oil, should form the basis of the diet. Bran biscuit, health bread, steamed wheat (Sec. X, No.3), dates, figs, raisins, grapes, acid and sub-acid fruits and berries will furnish sufficient nourishment and will serve to stimulate the peristaltic action of the bowels.

2. **A Sample Diet.** **Breakfast,** any kind of acid or sub-acid fruit or berries. **Luncheon,** raw vegetable salads with dressing of lemon juice and olive oil; dates, raisins and a small amount of either whole wheat bread, bran biscuit, shredded wheat or whole steamed wheat. **Dinner,** raw vegetable relishes and salad of green, leafy vegetables with raw grated carrots or turnips; a cooked leafy vegetable such as spinach, cabbage or Swiss chard; one potato, or in place of it a slice of whole grain bread; some sweet, alkaline fruit for dessert; buttermilk or yogurt. Fruit juices, either pure or dilute, may be taken between meals. This diet should be followed for two or three weeks.

3. **A Natural Laxative.** The treatment of constipation may begin by taking a mixture of bran, agar-agar and flaxseed to
be used two or three nights in succession in the following proportions: Mix two tablespoonfuls of bran, one tablespoonful of agar-agar and one tablespoonful of flaxseed. This must be eaten dry before retiring.

In order to soften and to remove old hard fecal encrustations from the colon a few colon flushings may be taken at the beginning of the treatment. Descriptions of colon flushing and of the necessary apparatus, posture, etc., are given in Sec. XVIII, No.7. While it is permissible to resort to a few thorough colon flushings at the beginning of the treatment, I am strongly opposed to the habitual use of enemas. This is bound to result in greater weakness and atrophy of the intestines. Filling the lower part of the intestinal tract habitually with large amounts of warm water not only dilates the already weakened intestinal wall but takes away the natural impetus to secretion. In other words, as the popular expression goes, "the more you flush, the more lazy the bowels become".

I have met many victims of this weakening practice who assured me that the longer they used the "rubber doctor" the more relaxed and weakened the intestines became and the more they suffered from indigestion, fermentation, gas formation and the effects of systemic poisoning. Therefore we resort to colon flushing only as a "crutch" in the beginning of treatment until the intestines become alive and active under natural diet and treatment. We advise patients to resort to flushing only when it becomes absolutely necessary. In that way they learn to take enemas at increasingly long intervals, forcing Nature to do the work in the natural way. Natural evacuation will be hastened and facilitated by going to the stool at certain stated times.

4. Hydrotherapy for Constipation. A cold sits bath should be taken every evening (with the usual restrictions for women). It has a splendid cooling and relaxing effect upon the abdominal organs. (Sec XIII, No. 13)

The abdominal bandage has all effect similar to that of the sits bath. It is cooling and relaxing, thus relieving the overheated condition of the intestines.

5. Exercises. The best exercises for overcoming constipation are those which bring the abdominal muscles into play. (Sec. XXI, No. 16 and Sec. XXIII, Nos. 6, 7, 8, 9, 14, 23) Aside from these special exercises, brisk walks in the fresh air have a splendid tonic effect upon the muscular apparatus of the digestive tract.

6. Massage. In stubborn chronic cases abdominal massage is absolutely necessary to attain speedy and satisfactory results. (Sec. XVIII, No. 1)

7. Neurotherapy. If lesions are present in that region of the spine which gives rise to nerves that supply the intestines, no permanent results can be expected until these lesions are corrected.
8. Orificial Dilatation is one of the most effective methods for the treatment of chronic constipation. It is fully described under Sec. XXVIII

SECTION XXVII

HEADACHE

Headache is usually but a symptom of disease. Somewhere in the body, though it may be due to local irritation by systemic or drug poisons. Diseased conditions and infiltration anywhere in the system are telegraphed to headquarters in the brain and there manifest in the form of venous symptoms, the most frequent of which is headache. Sometimes it is caused by defects of vision, or eye strain and may be alleviated by properly fitted glasses. This, however, cannot take the place of removing constitutional causes. Frequently the wearing of "eye crutches" prevents the locating and removal of the underlying causes and thus condemns the individual to the life long use of glasses, to constantly weakening eyesight and to chronic constitutional disease.

One of the most common causes of headache, as well as of eye trouble, is uric acid or pathogen poisoning. This has been fully described in Vol I, chap. XXIX. A typical uric acid headache is migraine or one sided headache, particularly annoying in the morning when the blood is loaded with pathogenic materials.

1. Bilious or Sick Headaches. Another common type is the so-called bilious headache. While usually attributed to an inactive liver, it may be caused in various ways. Pathogenic clogging of the liver will interfere with the elimination of bile products; these will remain in the circulation and cause general symptoms of biliousness, jaundice, nausea, vomiting and headache.

Pathogenic obstruction may be due to overeating, to the excessive intake of starchy, protein and fatty food, and to a deficiency of fruits and vegetables in the diet; or the discharge of the bile may be obstructed by sticky, colloid accumulations in the gall bladder and bile duct. In other cases the bile duct is contracted and obstructed through inflammation in the duodenum.

Anything that interferes with bile formation in the liver or its discharge from the gall bladder or bile duct, not only causes surging back of the bile into the general circulation but also a deficiency of it in the intestinal tract, which in turn gives rise to acidity of the intestinal contents, indigestion, constipation, fermentation and gas formation. This intestinal toxemia is reflected to the brain in the form of congestion and headache, and favors the formation of emboli (obstructive plugs) and the development of apoplectic strokes. Anything that tends to cause constipation and thereby intestinal toxemia
or auto intoxication will also help to produce acute or chronic headaches. The treatment for constipation is explained under Sec. XXVI, and also under Sec. XXVIII Orificial Treatment.

The headaches so far described are of the congestive type, characterized by excessive blood pressure to the brain. Anything that tends to raise the blood pressure will therefore create or aggravate these ailments. A common cause is pathogenic obstruction in the capillary circulation, which results in active congestion in the internal organs and the brain; or pathogenic obstruction in the lymphatic or venous drainage which interferes with the flow of the blood from the brain and thus causes passive congestion.

The foregoing remarks explain the effectiveness of a simple manipulative treatment which any layman can apply. The neck stretching movement is illustrated in Fig. 23a. The subject assumes a sitting position. The operator stands on either side, applies the thumb and the first and second fingers of one hand firmly to the base of the skull, while with the other hand under the jaw he lifts the head and stretches the neck gently but firmly upward and backward. The stretching should continue from thirty to sixty seconds.

This movement kinks the arteries and straightens and drains the veins, thus relieving the congestion in the brain. After slowly releasing the pressure, the operator firmly strokes the neck downward along the course of the main arteries and veins, on both sides. The stretching should be followed by a magnetic treatment. The operator takes the head of the patient between his hands and with his thumbs stretches the skin of the forehead outward, half a dozen to a dozen times, and then makes the regular magnetic strokes from the forehead downward and outward along the neck and arms. The various forms of magnetic treatment are fully described in Chap. XXXIV, Vol. I.

The operator while giving the manipulative and magnetic treatment must combine with these the right mental and psychical attitude as described in the chapter just referred to. If one of these combination treatments does not bring the desired result, it may be repeated if the attention of the subject can be temporarily distracted from his ailment so much the better. After an interval of five or ten minutes his headache will usually have disappeared.

2. Anemic Headache. This type of headache is caused either by great impoverishment in the quality of the blood or a deficiency of it in the brain. This condition frequently obtains in cases of anemia, leukemia, pernicious anemia, or where the flow of the blood to the brain is interfered with by a tumor,
aneurysm or other mechanical obstruction. While the congestive headache has violent, throbbing, paroxysmal pains, the anemic headache is accompanied by extreme dullness and lassitude. The former is characterized by heat and redness of the face, the latter by coldness, clamminess and pallor.

The manipulative treatment for the anemia headache is similar to the other. The hands are applied to the nape of the neck and under the jaw in the same manner, but instead of stretching the neck upward and backward, it is stretched upward and forward (Fig. 23b) This movement kinks the veins and straightens the arteries, thus allowing a greater flow of blood to the brain. The magnetic, mental and psychic treatments are the same in either case.

In all types of headaches the dietetic treatment must build up the blood on a natural basis and eliminate pathogenic encumbrances. The various regimens for this purpose have been given under Secs. I and X. In headaches of the congestive type, fasting is of particular value. If the trouble is caused by indigestion, biliousness and a fetid condition of the stomach, copious draughts of water as warm as it can be swallowed sometimes gives quick relief. If the "warm water flushing" causes vomiting, so much the better.

3. Nervous headaches may be caused by sudden fear, shock, excessive worry or anxiety. The preventive and curative treatment is given under "Nervous, Mental and Emotional Disorders." But even for nervous headaches constitutional treatment is essential. Persons in perfect physical condition are not likely to suffer from nervous, mental or emotional disorders of any kind.

4. Mechanical Lesions. In many instances headaches are caused by the impingement of luxated bones or strained muscles or ligaments on blood vessels or nerves supplying the brain or eyes. Luxation of the atlas, the topmost bone of the spinal column which carries the skull, frequently gives rise to this sort of headache. Luxations of one or more of the cervical vertebrae may have a similar effect. Such mechanical lesions must be corrected by manipulative (neurotherapy) treatment.

5. Drug Poisons. The most obstinate and severe types of chronic headaches are caused by drug poisoning. Nature has made ample provision for the elimination of systemic waste, but she never intended that the many forms of powerful poisons given under the guise of medicines, tonics and stimulants should enter human bodies. Therefore the organs of depuration have not been constructed for the elimination of these poisons. They accumulate in the system in certain parts and organs for which they exhibit special affinity, and there
become the source of constant irritation, frequently of actual destruction. Through diagnosis from the iris we have traced hundreds of cases of stubborn chronic headache to the action of powerful drug poisons in the brain itself or in other organs. Many such cases have been described and illustrated in Iridiagnosis, Vol. VI of this series.

The only way to overcome such headaches is to remove the poisonous irritants and stop their destructive effects by thorough systematic natural treatment as outlined under the sections dealing with chronic diseases.

SECTION XXVIII

ORIFICIAL TREATMENT

The following principles underlie the various methods of orificial treatment.

a) All the involuntary functions of the body such as circulation, respiration, digestion, secretion, elimination, etc., are under the control of the sympathetic nervous system.

b) Each of the pelvic outlets of the body is guarded by two sphincter or circular muscle bands. The lower (external) sphincter is under control of the will and is supplied by the cerebrospinal nervous system. The upper (internal) sphincter is not under control of the will and receives its nerve supply from the sympathetic nervous system. In this way a most important connection is established between these two nervous systems.

c) Over tension of these sphincter muscles produces impingement of the sympathetic nerve endings, thus lowering the vitality by exhausting the sympathetic nerve force, "on the same principle that electric energy is wasted by pressure on the button which rings the bell." In time such spastic contraction results in hypertrophy and atrophy.

d) By dilating the abnormally tensed outlets, this irritation of the sympathetic nervous system is relieved. Thereby nervous energy is economized, undue tension removed and functional activity of all the internal organs enhanced.

e) Dilatation of the sphincters of the orifices relaxes the vasomotor nervous system, which is under the control of the sympathetic, and thereby causes a widening and well marked flushing of the capillaries over the entire body thus aiding metabolism, oxidation and elimination of tissue waste and promoting the repair of diseased or injured tissues.

Orificial surgery, as the name implies, in order to relax contraction of the sphincter muscles of the body relies to a large extent upon surgical treatment. This, however, is not natural treatment. We avoid wherever possible any and all
mutilations of tissues and organs because these are always followed by more or less harmful after effects. Surgical treatment usually means serious injury to nerves, blood vessels, muscles, ligaments, and the formation of scar tissue or adhesions which, in turn, may cause impingement and interference with normal functions.

From our viewpoint such surgical mutilations are not only harmful but in most cases absolutely superfluous, because in natural methods of treatment we possess the means for relaxing abnormal contraction of tissues in any part of the body. In the following I shall describe the most common lesions of this character and their natural treatment.

1. Phimosis. Frequently the foreskin or prepuce of the penis of a male child or of an adult is so tightly contracted around the head or glans of the organ that it cannot be retracted. Sometimes the opening of the foreskin is constricted to the size of a pinhead, causing interference with the free discharge of the urine. Smegma, a sebaceous secretion of the glans of the penis, may accumulate under the tightly adherent foreskin and cause irritation, which frequently results in serious affections of the nervous system. The intolerable itching caused by such irritation not infrequently leads to masturbation.

The remedy of the orificial surgeon, as well as of the medical profession in general, consists of circumcision, that is, complete surgical removal of the foreskin. I have never been able to conceive of a valid reason for this barbarous practice, which always means mutilation of one of the most highly sensitive nerve centers of the body. It is a fact well known to nature cure physicians that cooling applications in the forms of sitz bath or friction bath have a cooling and relaxing effect upon all the abdominal organs, indicating that there must be intimate nerve connection through the sympathetic and cerebrospinal nerves between the internal organs and the glans penis and prepuce.

Mutilation of the sexual organs seems inexcusable when there are natural ways of attaining the desired results. In the majority of cases all that is necessary is to lave the head of the penis with cold water for a few minutes in order to produce partial anesthesia, and then to exert gentle backward traction on the foreskin. This treatment usually succeeds in from two to ten days in loosening and drawing back the foreskin.

If the constriction be so severe that traction does not succeed in overcoming it, or if the prepuce is adherent to the glans penis, a probe may be employed to loosen it or a small penile syringe may be inserted within the orifice of the foreskin so that water may be forced into the cavity between the glans and foreskin. Drawing the prepuce over the end of the syringe, an injection is made of warm water mixed with a little castile soap. This should be followed by two or three injections of clear warm water. This procedure not only removes fetid accumulations but also separates and dilates the adherent foreskin without irritation or injury to the parts. It expands the prepuce with an all around even pressure. This
treatment also should be followed by gentle backward traction.

Among several hundred cases thus treated I found only two which demanded surgical treatment, because the prepuce had grown so fast to the glans penis that it could not be removed by the natural treatment.

2. Paraphimosis. Paraphimosis results when the contracted prepuce yields to traction or slips back of its own accord, causing strangulation of the neck of the penis back of the corona. This results in compression of the urethra, retention of urine, and in shutting off the circulation in the extremity of the organ. The gland becomes congested and inflamed, and the foreskin is swollen with serous exudates. In order to prevent ulceration and sloughing of the parts, the foreskin must be brought forward over the glans penis without delay. I have always succeeded in accomplishing this by cooling water applications and absorbent packs followed by gentle dilatation and forward pulling of the constricted prepuce. In no case was it necessary to resort to surgical treatment.

3. Hooded Clitoris. The clitoris of the female corresponds anatomically and sexually to the penis of the male. It is a small erectile organ concealed beneath the labia minora, just in front of the urethra. The free extremity of this organ (glans clitoridis) is a small round tubercle of spongy erectile tissue and highly sensitive. This protuberance is not infrequently covered by a membrane under which secretions may accumulate as under the adherent male prepuce, resulting in nervous irritation. Many serious nervous ailments have been traced to this cause. The natural treatment here, also, consists in cooling applications and gentle backward traction or in loosening the skin with a probe. As a rule the difficulty is overcome more easily than in phimosis. In rare instances where the covering membrane is so tough and tightly adherent that it will not yield to the natural treatment, a small v shaped incision may have to be made in order to free the organ.

4. Dilatation of the Lower Orifices of the Body. The sex organs, as well as the entire system, receive their influx of life force through the sympathetic. The tonicity of the sexual organs therefore depends upon the integrity of that part of the sympathetic which supplies the pelvic organs. Since the secretions of the ductless glands of the sex organs exert a profound influence upon the tonicity of the organism in general, it will be seen how important it is that the sympathetic nerve supply to these organs be not interfered with in any way. Such interference results when the genito-urinary organs are either in an over irritated or atrophic condition. Irritation of the urethra or prostate gland by acute or subacute inflammatory processes causes sexual hyperactivity and a great waste of nervous energy and, through the ramifications of the sympathetic, it produces by reflex action nervous irritation in neighboring or even the most distant parts of the body.

Excessive irritation of the genital organs or the rectum, communicated to the vasomotor centers, may cause
constriction of the blood vessels and thereby congestion, pathogenic obstruction and inflammation in nearby or distant parts of the body predisposed to these conditions.

On the other hand, sexual weakness or atony diminishes the secretions of the sex glands, benumbs the nervous activities and retards heart action and circulation. Aside from excessive drainage of the sex fluids nothing else produces these debilitating effects upon the system like permanent contraction and hypertrophy of the rectal sphincters and of the tissues of the penis and the prostate gland. Such contraction may be the result of long continued irritation and hyperactivity due to excessive indulgence or self abuse, or it may be caused by gonorrheal inflammation, irritating drug poisons, or by long continued constipation with its deadening effects upon the sphincter ani.

The expenditure of nerve force is reduced to a minimum through complete rest and relaxation and its expenditure through voluntary activities ceases entirely during sleep, sound sleep, as is indicated by the disappearance of the aura. Anything which causes abnormal irritation, while awake or asleep, involves unnecessary expenditure. At this point it may be well to enumerate the various causes of nerve waste described in this chapter and in connection with other subjects.

a) Acute and subacute inflammatory processes affecting any part of the sympathetic or cerebrospinal system.

b) Roughened surfaces of internal membranes, especially at the orifices, fissures, papillae, piles, incipient tumors and other adventitious tissues (new growths) in the rectum, genito-urinary organs or in any other part of the body.

c) Nerve irritation caused by luxated vertebrae or other bony structures (chiropractic theory), or by impingement of connective tissues on nerve matter (naprapathic theory)

d) Nerve irritation due to discordant and destructive mental and emotional activities such as impatience, irritability, fear, worry, anxiety, anger, rage, fury, jealousy, self pity, as described in Section XXIX of this volume.

Nervous irritation from any of these causes if continued for a long enough time will result in atony, hypertrophy and atrophy of connective tissue and nerve matter, which in turn results in obstruction to the inflow of vital energy and its distribution through the organism. Acute and subacute irritation are indicated in the iris by white nerve rings; atony and atrophy by black nerve rings, as explained in *Iridiagnosis*, page 57

5. How to Stop the Leaks. Aside from the ordinary natural methods of living and of treatment there is nothing more effective for the relaxation and invigoration of the lower intestinal tube and of the sex organs than dilatation of the rectal sphincters, male urethra, and of the sphincter muscles of the vulvae, vagina and uterus. Alternating compression and
relaxation of the sphincters of these orifices has a wonderful relaxing and tonic effect upon the organs themselves and upon the entire organism.

It relieves abnormal tension and thereby allows a more copious inflow of vital energy through the sympathetic and prevents its waste through continual irritation while waking and sleeping. This restores the normal tonicity of the rectum and of the sex organs, which in turn insures normal evacuation of feces and urine, increased secretion of the ductless glands, and greater activity of all the vital functions of the organism, physical as well as mental and psychical.

Manual or mechanical dilatation of the lower orifices of the body is more invigorating than any medical tonic or stimulant, without producing deleterious after effects. It is a splendid means for reviving persons suffering from fainting fits, anesthesia, epileptic seizures, from opium or other poisoning, and from asphyxiation or drowning. Rectal dilatation is a splendid aid to promote recuperation from serious acute diseases, and to start the normal breath of the newborn infant.

A writer on orificial surgery discusses diseases of the lower intestinal canal as follows:

"Diseases of the lower portion of the intestinal canal are exceedingly common. There is probably no one organ or locality of the human body so subject to a variety and complexity of diseased conditions as this.

"Experience and observation for many years have convinced us of the fact that rectal diseases are the foundation and cause of very many other grave forms of chronic disease which it is impossible to cure so long as the rectal lesion holds. Very many serious uterine affections that baffle the skill of the practitioner, are thus obstinate because he has failed to discover or cure the rectal complications.

"We have no doubt but what many cases of mental aberration are caused by lesions of the intestinal canal and especially of the rectum."

6. Contraction of the Sphincters of the Rectum. This condition interferes seriously with the evacuation of the feces; it frequently results in stubborn constipation, reabsorption of toxic materials from the lower sections of the intestinal canal and in all the evils of autointoxication.

Causes of Tight Sphincters

7. Reflex Irritation. In many instances over tension of the sphincter muscles is due to reflex irritation associated with disturbances of the rectum, uterus, urethra, prostate, bladder, etc., caused by acute or chronic inflammation, tumors, hemorrhoids, fissures, rectal pockets which retain fecal matter, etc.

In discussing the effects of rectal pockets and papillae, Dr. Pratt states that they "induce sexual over activity, disturb
colonic peristalsis and lower vitality by inducing chronic over
tension of the internal sphincter and shallowing respiration,
inviting stomach, heart, lung and head troubles, as well as
interfering with capillary circulation throughout the body."

Granting that artificial dilatation will beneficially influence
these conditions by relieving nervous irritation, the fact
remains that the tightening of sphincters is a symptom, not a
primary cause of the condition, and these primary
manifestations of disease must be removed by natural methods
of treatment.

8. Technique of Rectal Dilatation. Alternating
compression and dilatation of the sphincter and of the
ganglion impar situated on the internal convexity of the
coccyx, and of the sympathetic nerves which radiate from it to the
lower part of the rectum and the pelvic organs, is best
produced by manual treatment. The operator inserts the
forefinger as deeply as possible and exerts firm pressure on
the internal sphincter. The degree of pressure necessary to
obtain the best results can be regulated much better by manual
treatment than by a mechanical instrument. It offers the only
means of forcing back into normal position the bent coccyx
which frequently causes pressure on the rectum and ganglion
impar, or tension of muscles and ligaments attached to the
coccyx, which may result in spastic contraction of the rectum
and the most stubborn constipation. A rubber glove is worn
while giving the treatment.

9. Mechanical Dilatation. Several types of rectal dilators
are on the market for the use of the laity. The results of such
home treatment are not always satisfactory because rectal
dilatation requires the skill of a physician who can judge the
degree of dilatation necessary in each case, the length of each
treatment and the frequency with which it should be repeated.

It is essential that the internal sphincter should be dilated
without exerting undue force on the external sphincter. When
this has been accomplished the speculum is withdrawn
without closing it so as to dilate the external sphincter from
within outward, thereby imitating Nature's way of evacuating
the feces which produces natural dilatation of the sphincter
ani with its tonic effects upon the system.

10. How to Use Rectal Dilators. Dilators made of hard
rubber, wood or glass may be procured in any drug store.
They come in sets of four. One should begin with the largest
size consistent with comfort. The dilator should be lubricated
with clean olive oil, vegetable oil or pure castile soap.

The size of the dilator to be employed depends upon the
size and relaxability of the sphincters; the length of time it is
allowed to remain should be determined by the individual
condition and the amount of reaction to be desired.
Respiration and capillary circulation are more profoundly
stimulated by rectal dilatation than by the treatment of the
genito-urinary orifices.

The instrument is gently passed well into the rectum, as far
as the flange or rim will admit it. The flange prevents the
dilator from slipping in too far. The best position for the
patient to assume is lying on the side with the knees drawn
up. Hold the dilator in place a few moments, until the inner
sphincter closes tightly around it. Then it will be retained. It
may remain in position from ten minutes to half an hour, or as
long as one or two hours.

The dilator may be inserted either on retiring at night or on
waking in the morning, or at any other convenient
time during
the day. In case of obstinate constipation it should be inserted
after waking in the morning and retained about half an hour or
more. This usually induces a natural bowel movement. If used
at night it will promote natural, refreshing sleep. The patient
should go to sleep if possible and not lie awake to time
himself, as no harm can result if the dilator be retained all
night. Dilatation may be repeated daily, every second day or a
few times a week, according to individual needs.

Since it has taken years of wrong living, neglect and abuse
by drugs, to create the chronic conditions, results cannot be
expected within a few days or weeks. While some stubborn
cases show improvement at once, others require time and
patience. As before stated, in order to attain quickest and best
results the mechanical treatment must always go hand in hand
with the general natural regimen and neurotherapy.

By improving the nerve and blood supply and by
establishing better drainage, rectal dilatation will not only help
to overcome stubborn constipation but also promote the
absorption of piles, fissures, rectal pockets, papillae and other
abnormalities. More efficacious and safer than the ordinary
rectal plug are instruments especially devised for this purpose,
in the hands of the trained physician or nurse. Best adapted
are the rectal speculum or instruments of similar construction.

11. Dilatation of the Sphincters and Tubes of the Genital
Organs. One of the common causes of sexual weakness or
complete impotence, as already explained, lies in contraction,
hypertrophy and atrophy of the sphincters of the rectum.
These conditions curtail the inflow of vital energy into the
sexual organs and obstruct the blood supply to the erectile
tissues of the penis or the clitoris. Similar effects upon the sex
functions result from contraction and strictures of the tissues
of the penis and prostate glands.

Aside from rectal dilatation, the passing of graded steel
sounds, either cold or at blood heat temperature, is the best
remedy for correcting the abnormalities just described.
Sounds, as well as rectal plugs, have both local and general
effects upon the circulation and the nervous conditions of the
system.

In case of excessive irritability and abnormal sexual
excitation leading to involuntary emissions and masturbation,
the mere introduction and removal of a warm sound will
immediately reduce the hyperthesia and restore the
sympathetic to its normal tone. Where excessive irritability
has become chronic the treatment must be repeated daily or a
few times a week until the desired results are obtained.

In states of sexual weakness or impotency, which may result in a sluggish, indolent condition of the entire organism and in physical and mental debility, it may be best to leave a warm sound in position for from a few minutes to one or two hours, and to follow this with the introduction of a cold sound which should be left in position not longer than a few minutes. This treatment may be repeated once, twice, or in stubborn cases, three times a week, until normal tonicity of the sex organs and of the system in general has been restored or at least greatly improved.

No routine rules for the use of sounds can be prescribed; the treatment must be adapted to individual conditions. The treatment is very beneficial for the cure of gleet and strictures. It is equally as serviceable in spastic contractions of the urethra and prostate as in relaxed and flabby conditions of these organs. In order to insure good results from the passing of steel sounds for any purpose whatsoever they should be made to pass as far as the interior of the bladder. Their good effects locally and constitutionally depend on their action upon the prostatic inch of the urethra.

12. Dilatation of the Sphincters of the Female Organs.
Dilatation applied to these parts is beneficial to relieve irritation and contraction as well as abnormal relaxation and atony. In other words, it is effective for the cure of spastic contraction as well as for atony, atrophy and paralysis. The former conditions of the vulvae, vagina and uterus occur most frequently in unmarried women and in those of the married who have never borne children. Abnormal relaxation of the parts is frequently the result of sclerosis of the spinal cord, of tubercular processes and of excessive strain in delivery.

The various parts of the female sexual apparatus are so closely related and associated in construction and function that tension or relaxation in one part affects the other parts as well. Undue tension of the vagina may be overcome by careful dilatation with the rectal bivalve, but care must be taken not to injure the vaginal walls, as this might have a tendency to aggravate rather than to relieve the abnormal irritation and contraction of the parts. Dilatation of the uterus is accomplished in similar manner as that of the male urethra by the insertion of graded steel sounds; first smaller, then larger sizes are employed until resistance increases sufficiently to procure the necessary dilatation of the sphincters of the external and internal mouth of the uterus.

Dilatation of the sphincters of the atonic female organs not only raises their tonicity but through increasing the supply of vital energy, stimulating the capillary circulation and procuring better drainage, greatly facilitates the absorption of roughened membranes, papillae, fissures, scars and incipient tumors; however, the treatment must be executed only by physicians well trained and experienced in the use of the instruments. The latter must always be well sterilized and dipped in clean olive oil before insertion.
13. Dilatation by Neurotherapy Treatment. All the beneficial effects resulting from mechanical dilatation of the lower orifices of the body can be obtained also, more or less completely, by neurotherapy and hydrotherapy treatment. To procure the best results all three methods should be applied in proper combination.

14. Coccygeal Lesions. (a) Anatomy of the Parts. The coccyx or end of the spine consists of four small bony segments which are fused into a single curved bone about one inch in length.

At the junction between the coccyx and the sacrum, spinal nerves emerge that supply the external sphincter muscle which guards the lower opening of the bowel.

b) Occurrence of Lesions. Notwithstanding the fact that injuries to the coccyx frequently give rise to obscure neurotic disorders, the literature on this subject is deplorably meager. Evidently the reason why so few cases are reported in professional journals and text books is because sufferers from an annoyance 'at the end of the spine', will, from motives of delicacy, adopt semi-invalid ways rather than seek professional aid.

Coccygeal lesions occur most frequently in women, and play an important part in a large number of diseases peculiar to the female genital apparatus.

15. Causes of Lesions. (a) Falls or blows on the base of the spine are mishaps which the majority of us have experienced some time or other during our lives.

b) Jars to this region frequently occur while riding on horseback.

c) Faulty posture while sitting, if continued for any considerable period of time, frequently gives rise to coccygeal lesions.

d) Childbirth. Injuries are frequently sustained to the coccyx at childbirth, due to the pressure of the child's head during its passage through the outlet of the pelvis. Normally the pelvis yields to the head of the child so as to increase the diameter of the pelvic outlet, but in cases where the pelvis is too small or where the head of the child is abnormally large, or in cases where women give birth to their first child at an age when the coccyx is partially or completely ossified to the end of the sacrum, the coccyx is very susceptible to injury. The exact manner in which these lesions as well as all other spinal lesions are produced is described in Vol. I, Chap. XXXII, on "Manipulative Treatment".

16. Effects of Coccygeal Lesions. An abnormally anterior position of the coccyx encroaches upon the posterior wall of the rectum, thus mechanically giving rise to rectal constipation with its train of complex after effects.

Impingement of the coccygeal nerves produces overtension
of both internal and external sphincters of the anus and thereby wastes nerve energy as previously described.

In individuals with rheumatic or gouty tendencies an inflammatory condition called Coccydynia frequently develops in the region of the coccyx after injury. Coccydynia is characterized by a severe distressing pain which is aggravated by walking, coughing, sneezing, defecation, sudden changes of posture from standing to sitting, or any movement which involves the muscles attached to the coccyx.' The usual allopathic treatment for this condition consists of administering salicylates and pain killing remedies. In obstinate cases the coccyx is excised. Such methods of treatment not only fail to remove the constitutional cause back of this condition but the surgical removal of the coccyx leads to chronic lifelong irritation of the sphincter muscles of the rectum.

17. Coccygeal Relaxation. The same principle laid down for the treatment of other spinal lesions should be followed in case of coccygeal lesions (Vol. I, Chap. XXXII). The muscles attached to the coccyx should be thoroughly relaxed before any attempts are made at adjustment. In all cases where tenderness is present inhibition should be given.

Inhibition in the region of the coccyx exerts a marked beneficial effect on a host of neurotic disturbances that fail to respond to other methods of treatment alone. This is probably accounted for by the fact that such inhibitive treatment exerts a profound relaxing influence on the sphincters, and through these on the entire sympathetic nervous system, by acting upon the ganglion impar (group of nerve cells) situated on the anterior surface of the coccyx. This ganglion constitutes the point of union between the left and the right sympathetic chains and with the end filaments of the cerebrospinal nervous system.

This sympathetic relaxation is administered by applying externally strong and persistent inhibition on either side of the coccyx as well as on the following nerve centers along the spine:

a) Tender spots along the sacrum.

b) The posterior superior spine of the ilium.

c) On both sides of the spinal column on the level with the spines of the scapulae.

d) Over the superior angles of the scapula.

This inhibition is given for about five minutes at a time on one or all centers. The treatment is repeated from twice a week to once in two weeks or longer. In many instances vigorous healing crises develop as a result of such treatment. For this reason it is wise for patients to be in an institution when such treatment is administered.

18. Tonic and Relaxing Effects of Cold Water Treatment. The cold sitzbaths, Kuhne' friction baths and the
application of cooling compresses and cold packs to the abdominal and pelvic parts undoubtedly have effects upon the sympathetic nervous system similar to those produced by mechanical dilatation and coccygeal inhibition. The cold applications to the lower orifices and glans penis produce temporary contraction followed by relaxation of the parts, flushing of the capillaries, and a decidedly tonic effect upon the nerve endings of the sympathetic and the cerebrospinal system in and around the orifices. Similar temporary contraction with following dilatation of the millions of tiny cutaneous orifices all over the body resulting in a general flushing of the capillaries and in profound excitation of nerve reflexes and peristaltic action of the blood vessels all through the body is obtained by the various cold water applications, such as the natural bath, cold ablutions, blitzguss, barefoot walking in the dewy grass, as well as the nude air and light baths.

19. Dilatation of the Nasal Orifices. The beneficial effects of cold water sniffing are due not alone to the mechanical clearing of the nasal passages from pathogenic excretions, but also to the tonic effects of the cold water flushing upon the sympathetic and cerebrospinal nerve filaments in the membranes of the nasal passages. This undoubtedly explains the tonic effect of the cold water sniffing, not only upon the physical functions, especially the respiration, but also upon the mental activities.

These natural methods with their profound effects upon the system make entirely unnecessary surgical dilatation of the orifices, curetments, shortening of ligaments, extirpation of piles and the surgical treatment of fissures, papillae and incipient tumors. Such surgical mutilation is suppressive, not curative, and is usually followed in time by serious chronic after effects—the "mysterious sequelae" of medical science. We must remember also that all the abnormal conditions discussed in this chapter are secondary effects, that the primary causes lie more or less in food poisoning, in the irritating and destructive effects of poisonous drugs, and in wrong thinking and feeling.

SECTION XXIX
NERVOUS DISEASES

It is safe to say that one-half of all the patients who come to us for consultation and treatment have been told that they suffer from nervousness. After having given a long recital of their aches and pains, they usually wind up by saying "All the doctors I have consulted tell me it is my nerves", or, "it is nervousness", or, "it is neurasthenia".

What do these terms mean! Do they actually explain the nature and the causes of the patient's ailments! They do not. They are merely convenient terms for covering the doctor's
ignorance. A well known nerve specialist in Chicago delivered a lecture before a medical society on the subject of neurasthenia. Addressing the assembled physicians, he began as follows: "A patient comes to you complaining that he is suffering from headaches, physical and mental weakness, pressure on top of the head, ringing in the ears, insomnia, irritability and most of the other symptoms of nervousness known to medical science. After a thorough examination you find that all his vital organs are intact; there is nothing wrong with him physically; in fact, you do not know what ails him—that is neurasthenia."

There are many other Latin and Greek names for diseases which serve the same purpose to cover the doctors' ignorance. Still, the patient who has consulted the "great specialist" goes home perfectly satisfied so long as he gets a Latin name for his troubles. When he is told he has rheumatism, neuralgia or neurasthenia he thinks he knows what is the matter with him.

It does not require a medical education to tell a patient that "it is the nerves" or "rheumatism" or "neurasthenia" when his body is racked by aches and pains and his mind is on the verge of insanity. The brain and the nerves will not give out unless there is some good reason for it, and the doctor's diagnosis, in order to be of any value to the patient, should define the causes of the weakness and irritation of brain and nerve matter.

1. The Chemical Causes of Nervous Diseases

The diagnosis from the iris and the examination of the spine, as given in our institutes, throw considerable light on the causes and the rational treatment of nervous diseases. In the great majority of cases when examining the eyes of "nervous" and "neurasthenic" patients, the first thing to attract our attention is a darkening or decided (discoloration of the areas of the stomach and bowels, which are located directly around the pupil. The brownish, reddish, yellowish and other abnormal pigmentation indicate; various forms of drug poisoning that have resulted in a diseased condition of the organs. These signs in the iris mean that the membranous linings of the stomach and bowels are in a sluggish, atonic condition and this is bound to be followed by very serious consequences.

The membranous linings of the digestive organs serve two purposes—elimination and assimilation. Certain cells and glandular structures in these membranes absorb the food materials and after purifying and modifying, transmit them into the blood and lymph streams. Other cell and glands in the intestinal membranes excrete morbid matter and systemic poisons.

From the foregoing it becomes apparent that a sluggish inactive condition of the mucous membranes lining the digestive tract must have the following detrimental results:

First: The food materials are not properly assimilated and so pass out of the body without being utilized. We must
remember that the foods, while they remain in the intestinal tract, are not yet in the body. They do not pass into the body until they are absorbed through the walls of the intestines into the venous and lymphatic circulation. Defective assimilation of this kind is aggravated by the use of mineral oils. While these promote evacuation by creating a slippery condition of the bowels, they do not do anything to clear away the colloid substances which dog the absorbent lining of the intestines—therefore these oily laxatives prevent absorption of the food materials through the intestinal walls into the circulation. In time they aggravate chronic constipation because they obviate the necessity for natural effort.

Second: The elimination of waste materials and systemic poisons through the intestinal membranes is seriously handicapped, which results in systemic poisoning or, as it is called by the medical men, autointoxication.

Furthermore, under normal conditions the membranous linings of the intestinal tract throw off mucoid secretions which lubricate the bowels and facilitate the movement and discharge of the food waste and feces. Certain cell linings in the stomach and bowels throw off secretions containing important digestive ferments on which depends the proper digestion of food materials.

What are the inevitable effects of such abnormal conditions in the digestive organs? If the intestinal membranes do not absorb the food materials the blood and lymph streams are deficient in nutritive elements and cannot properly feed the brain and nervous system. These, as well as the rest of the body are starved.

Somebody has expressed this in the words, "Nervousness is the cry of the nerves for food". While this is partially true, the nerves are also irritated by the systemic poisons which circulate in the blood stream as the result of the retention of feces and defective elimination. No wonder the nerves weaken and cry with pain when they are thus starved and poisoned at the same time.

Systemic poisoning is seriously aggravated by a sluggish, atrophic condition of the skin. This is indicated in the iris by a heavy black ring along the outer edge, which is visible more or less distinctly in the eyes of most people. This atrophic condition of the skin is caused largely through warm bathing from the time of birth, the wearing of heavy, dense clothing, and through clogging and weakening of the skin with antiseptic powders, salves, lotions, etc., used for the suppression of skin eruptions, and by toilet preparations containing substances injurious to the life of the skin.

When the bowels and the cuticle are in a semi-paralyzed condition the kidneys have to do more than their own share or the work of elimination and in turn become clogged and inactive. This is shown in the iris by chronic defects in the areas of these organs.

From the foregoing it becomes apparent that
malassimilation, malnutrition and defective elimination are the most common causes of nervous diseases. What is the usual treatment in such cases? The weakened nerves are artificially and temporarily stimulated by poisonous drugs and tonics, only to become more thoroughly paralyzed, for all artificial stimulation is followed by corresponding weakness and atrophy. The temporary stimulation may be produced by alcohol, coffee, tea or nicotin. Infinitely worse in their paralyzing effects upon the system than these food, drink and tobacco poisons are drug poisons like quinine, digitalis, arsenic, strychnine, etc., which constitute the active principles in medical tonics. The diagnosis from the iris proves conclusively that these drug poisons concentrate in certain parts of the body for which they have a special affinity and then become the cause of more serious troubles. In fact, as we have learned in other parts of this volume, the most serious nervous symptoms are due to the presence of drug poisons in the body.

Aches and pains, restlessness and insomnia are suppressed with bromides, morphine, coal tar preparations and other sedatives, hypnotics and "pain killers". These poisons merely benumb and paralyze brain and nerve matter into temporary insensibility, leaving them in a still more weakened and diseased condition but doing nothing to remove the underlying causes of the nervous or neurasthenic ailments.

The only way this can be accomplished is to build up the blood on a natural basis through proper diet and to make the organs of assimilation and elimination more alive and active through natural methods of living and treatment. A natural diet, well suited for this purpose; is outlined in Sections I and X. In the treatment of chronic ailments this general dietetic regimen must be modified or interchanged with periods of raw food diet, fasting, etc., according to the individual requirements and changing conditions of the patient. The various methods of manipulative treatment are important.

2. Mechanical Causes of Nervous Diseases

Let us now consider the mechanical causes of nervous ailments. The nerves may be irritated or benumbed not only by food and drug poisons but also by mechanical lesions in the spine or in other parts of the framework of the body.

According to physiological law, irritation at any point along the course of a nerve is communicated to all the branches of that nerve, similar to the way in which an electric current introduced at any point of a network of copper wires, if not checked or diverted, will travel over all the wires connected with that system.

Thus irritation of a nerve trunk will be transmitted to all the cells and organs supplied by that particular nerve trunk and its branches. In this manner many serious disorders are brought about.

Frequently patients come to us who have been treated for many years for "sciatic rheumatism". We find that one or both
hip bones are subluxated (slipped innominate). In such cases a few manipulative treatments replace the bones, remove the abnormal pressure and tension and thus cure the "chronic sciatica". Other patients have suffered for years from chronic headaches, nervousness, insomnia, eye troubles, etc. They have swallowed large amounts of poisonous sedatives, anodynes and hypnotics. Upon careful examination we find spinal lesions in the region of the neck. When these lesions are corrected the nervous symptoms disappear. In similar manner irritation of any one of the nerves passing out from the spine may cause pain or abnormal function in the corresponding part of the body.

For such conditions there can be but one remedy, namely, the correction of the mechanical lesions in the framework of the body which give rise to them.

For a detailed discussion of this topic see section entitled "Manipulative Treatment" in Vol. I of this series.

3. Mental and Emotional Causes of Nervous Diseases

While studying mental and emotional causes of disease we must realize that every mental and emotional vibration is instantly transmuted into the physical material vibrations of the physical body. I would define the fundamental law of mental therapeutics as follows: Vibrations originating on one plane of being—physical, mental or psychical—are by continuity transmuted into the vibratory conditions of the other planes.

Thus physical vibrations become mental or psychical vibrations, and vice versa. "As from below so from above; as from above so from below."

The trouble with many representatives of the physical and of the mental and spiritual schools of healing is that; they apply the law in only one of its phases. While it is true that habitual irritability will "sour the bile and poison the liver", it is just as true that an excruciating toothache or any other kind of long continued physical pain will affect the mental and emotional vibrations unless a person possesses superhuman self control.

Every mental, emotional and psychical vibration is instantly telegraphed from the seat of consciousness in the physical and spiritual brain centers over the nerve trunks and filaments to every cell in the body, and there transmuted into the vibrations of physical health and well being, or into physical irritation and disease.

In another chapter of this volume I have illustrated this transmutation of mental and emotional vibrations somewhat as follows: It is a well known fact that dry sand on a glass plate placed on top of a piano will arrange itself into harmonious designs in accordance with the musical sounds elicited from the instrument. Thus purely mental or emotional musical vibrations are transmuted into the material configurations of the sand. The melody produced from the
instrument had its conception in the mind of the composer. This musical conception he transmuted into corresponding sound vibrations. These in turn were translated into written notes on paper, thus completing the transmutation from the purely mental and emotional into the physical ink and paper. Then again, the player translates the written notes into musical sounds from the piano and these musical sound vibrations cause the sand on the glass plate to be grouped into orderly configurations of geometrical designs. It would be interesting to know what sort of higher and finer vibrations paint the flowers and ferns on the frozen window pane.

Another illustration in connection with this theme is the music roll of a pianola. Stretch out one of these sheets and observe the wonderfully symmetrical and geometrical designs in the arrangement of the perforations. The perforations stand for musical notes and these for musical sounds. Musical sounds interpret the emotions of the human soul—"music is the established harmonic relationship of the soul's emotions to the universe of sound". Every musical note expresses some vibration in the gamut of human emotions, from the deepest notes of misery and despair to the highest vibratory expressions of love and happiness.

In the Nature Cure Catechism, I have defined health as "harmonious vibration of the parts and particles composing the human entity on the physical, mental and moral planes of being". Disease is defined as "inharmonious or discordant vibration of the parts and particles composing the human entity, on one or more planes or being".

Health, self content and happiness constitute the music of the soul; discontent, unhappiness and physical disease, discordant, nerve-racking noise.

With these facts in mind, how can we afford to play the discords of fear, anger, jealousy, revenge, greed and self-pity on the harp-strings of the soul!

Let us see just how the mental and emotional discords become physical agony and disease.

4. Fear

The most destructive of all emotions is fear. It has a benumbing and paralyzing effect upon the body. Its physiological effects resemble those of freezing. A person freezing to death and one agitated by great fear and anxiety present a similar appearance. In either case the body is bent, cramped and trembling, the face is blanched, the teeth chattering. Cold shivers chase down the spine and through the benumbed extremities. The blood vessels, nerve channels and cells of the body are benumbed and congealed, causing obstruction to the free flow of the nerve and blood currents, thus shutting off the influx of the vital force. It is this obstruction to inflow of the life force that causes death by freezing and also causes death under the stress of some fear or great anxiety.
People indulging habitually and continually in the fear-and worry habit may not die at once from the effects of it, but they are nevertheless committing slow suicide through psychical refrigeration. They are effectually reducing the inflow of the life force, thus lowering their vitality and resistance to the destructive influences of systemic poisons and disease taints.

Furthermore, as I have pointed out, these vibrations are directly transmuted into the corresponding conditions of physical disease in the tissues of the body. The atoms and molecules of the cells arrange themselves into disorderly configurations and produce inharmonious and discordant vibrations just as surely as noisy racket produced on the piano will throw the sand on the glass plate into disorder.

People affected by these destructive thought habits may answer: "It is easy enough to say these things, but how can I prevent fear and worry thought from entering my mind!" As usual, ignorance is at the bottom of the trouble. People can control their thinking and feeling just as surely as their eating and drinking, but unfortunately they have never been taught self-control nor even the possibility of self-control in these matters. It is the lack of such psychological teaching and training from early youth that accounts for untold suffering, physically, morally and psychically.

Fear manifests in many forms and phases, such as fright, terror, despair, apprehension, anxiety, mistrust, alarm, horror, despondency, melancholy, cowardice, doubt, suspicion, etc. These mental, emotional and psychical vibrations differ only in degree of destructiveness. All must be held in abeyance and eliminated by self-control. This will become easy when we consider the utter uselessness of fear in its various manifestations. While fear is a natural impulse of the soul and useful in so far as it gives us warning of approaching or imminent danger, weak surrender to this emotion robs us of our strength and clear vision, thus making it easier for the threatened evil to overpower us.

Fear is faith in evil. It is a perversion of the great law of faith. He who fears a thing has faith that it can and will master him; thus he becomes a psychological coward and the thing he fears will surely overpower him. How much better is it to profit by the constructive workings of the law than to be destroyed by its evil effects. As surely as fear vibrations benumb and congeal the channels of life, just so surely will hope, faith and confidence in God and man and in the healing forces within relax the whole system, increasing the influx of vital force, thus invigorating and harmonizing the vibrations on all planes of being.

All of us have been at times benumbed and paralyzed by sudden fear, and many when weakened by physical or mental disease have experienced the wonderfully tonic effects of sympathy, love and joyful emotions. Cheerfulness is the best of all tonics and love, the greatest Physician. Increasing health, strength and happiness depend upon higher, more refined and more rapid vibrations on the mental emotional and psychical planes of being. The highest and finest
vibration in the universe is love; therefore is the love vibration the greatest of all healers. Love for humanity and sympathy with its suffering was the secret of the healing power of the Master, Jesus. It is the modus operandi of magnetic and spiritual healing.

5. Anger

While fear freezes, benumbs and paralyzes the organism, anger manifests in the opposite conditions of abnormally increased excitement and heat. As fear corresponds to freezing, anger and its kindred emotions affect the body like a consuming fire. They may well be called psychological combustion. Anger manifests in various phases and degrees of intensity, such as impatience, irritability, ill temper, resentment, hatred, rage, fury, revenge, bitterness, indignation, exasperation, malice and destructiveness.

These violently destructive emotions act on the physical body like fire. A person thus agitated presents the appearance of one overheated. The face is flushed, the blood pressure to the brain is greatly increased, which may result in apoplexy or in heart failure. The brain is congested as if by the effects of alcohol. As congestion in the lungs or other vital organs of the body tends to destroy the tissues of the affected parts, so also congestion of the brain, caused by wrath and fury, disrupts the subtle molecular structures of brain and nerve substances. One who is inflamed with anger is as irresponsible as one intoxicated with fiery liquor. The crimes of rage intoxication are as frequent and as deplorable as those committed under alcoholic stimulation. Nothing corrodes and frizzles the nerves so badly and wastes nerve force so wantonly as the consuming fires of anger and kindred emotions.

Excessive stimulation is always followed by corresponding depression, weakness and collapse. He who succumbs habitually to violent emotions slowly but steadily weakens his physical organism and lowers his power of resistance to destructive influences on the physical, mental and spiritual planes of being, thus inviting nerve exhaustion and paralysis.

Any and all discordant and destructive mental and emotional vibrations interfere with and obstruct the inflow of the life force, lowering the vitality and undermining physical and mental health. This is true of anger as well as of fear and of all other forms of destructive vibrations. Furthermore, the psychical wireless connects the unhappy victim of wrath and fury with the abodes of the most vicious and cruel beings on the earth plane and on the astral and spiritual planes, thus opening his soul to influx from these hellish spheres of cruelty, remorse and despair, and thereby intensifying his own unhappy condition.

The only remedy for these consuming diseases of the soul is self control; the making of new records in the plastic gray matter of the brain, records attuned to the vibrations of patience, forbearance, sympathy and brotherly love. We must either acquire constructive habits of thinking and feeling, or suffer the tortures of alternating nervous and emotional
excitation and exhaustion. Thus we create within ourselves our own heavens or our own hells.

6. Self Pity

Self pity in its vibratory nature and in its effect upon body, mind and soul, closely resembles the ravages of tuberculosis. It is psychological phthisis. A person affected by this degrading phase of emotional self-indulgence presents the miserable, haggard, negative appearance of a consumptive; The victim of self pity assumes that he is being unjustly dealt with by Providence, by fortune and by his fellowmen. He considers himself a martyr, enduring undeserved hardships, privations and injustice. This results in resentment, gloom and depression. It effectually kills cheerfulness, ambition and virile initiative.

This type of psychical consumption affects those possessed of great wealth and of the most wonderful opportunities in life just as frequently as it does those who actually have to endure the greatest privations. The daughter of one of our best known multimillionaires has been confined for many years in a private sanitarium in France. She is obsessed by the delusion that she is facing extreme poverty and the poorhouse, or that she will die of starvation for lack of means to procure food. What a living travesty this is on the popular belief that great wealth secures happiness!

Such cases are not at all uncommon among those possessed of immense wealth. They prove that the cause of this psychological disease does not lie altogether in outward circumstance, but rather in the emotional and psychical life of the sufferer. Such ego maniacs are the product of self centered egotism. If they had paid a little more attention to the real privations and suffering of their fellow beings instead of brooding over their own real or imaginary troubles, they would have escaped the ravages of psychical phthisis.

Sometimes these victims of self-pity are aroused out of their miserable mental dejection by some real trouble or misfortune. A splendid illustration of this is "Mrs. Gummidge" in Dickens' story of "David Copperfield". For many years she had pitied and bemoaned herself as a "lone, lorn creatur"; but when real misfortune struck the family through the elopement of Emily, then sympathy and pity aroused her from her self centered condition and changed her into a veritable angel of mercy who lightened the gloom of the unhappy family by cheerfulness and unselfish service. Forgetting her own imaginary troubles and lonesomeness, she underwent a truly wonderful psychical chemicalization through the magical reagents of pity and sympathy.

In my lectures I frequently take occasion to remind our friends that the best way to help themselves is to help other—that there is no better way of increasing the influx of the healing forces than by treating others for health and strength and happiness. I say to them, "There are those around you who need help just as much as or more than you do—some of them as yet unable to help themselves. Treat these weak ones
mentally and spiritually; strengthen them by a kindly look and a word of encouragement. You will be surprised how this will increase the flow of vital energy into your own bodies." These higher and finer forces can be received only as we give. Selfish brooding on our own troubles and self pity effectually shut off the inflow on life force, while sympathy and unselfish service open wide the channels of life and stimulate the flow of vital energy.

A well known ancient legend strikingly illustrates the utter foolishness of self pity. The people of a certain country had become very much dissatisfied with their sufferings. Each one believed his own cross was much larger and heavier than that of his neighbor. An angel of God appeared among them in human form and told them to bring their crosses and deposit them in one great heap, when everyone would be allowed to select a burden which he deemed lighter than his own. The people greatly rejoiced at this good fortune, discarded their crosses and proceeded to choose what they thought were lighter ones. However, their happiness at the change was not of long duration. One after another they soon returned, confessing dejectedly that the new cross was heavier and more painful to carry than the old one and asking to be allowed to take up again the old accustomed burden which a wise Providence had adjusted to each one's needs and powers of endurance.

Those who consume themselves in self-pity forget that this life is not intended to be a continuous Sunday School picnic; that, on the contrary, it is a school of personal and persistent effort for self development of our latent faculties, capacities and powers, through the use of reason, will power and self control; that only through overcoming evil in its many forms can we educate and strengthen our mental and psychical muscle; that evil on all planes of being is constructive in nature and purpose; and that there is no suffering, disease or evil of any kind anywhere unless the law has been transgressed somewhere by someone. These transgressions of the law may be due to ignorance, to indifference or to willfulness and viciousness. The effects will always be commensurate with the causes.

When we look upon evil from this viewpoint it loses its terrors. Then we look upon it as a healing crisis necessary to eliminate the destructive effects of ignorant or willful violation of Nature's laws. Thus we learn to overcome evil, not through anger, resentment and self-pity, but through cheerful compliance with the law.

Many pity themselves as martyrs to duty, martyrs in the service of their relatives and friends, martyrs to social conditions. They never stop to consider in how far they, themselves, help to create these unfortunate conditions through their own destructive thinking, feeling and doing. A lady remarked to her friend, "I don't understand why it is, but every time I move I find bad neighbors." Her friend answered, "Is it not possible that when you move you take the worst neighbor with you?"
If our surroundings and our neighbors do not suit us, it is a sign that we are not much better ourselves. If we were better than they we would probably be now in some higher sphere of life and action. The fact that we are here indicates that we need the lessons to be learned on this plane, and we shall not escape to more refined surroundings and better society until we become fit to maintain more refined and more sympathetic associations with our fellow beings. It is safe to assume that at each new birth, or as we now call it, at death, we gravitate to those spheres of life and action for which we are best suited. What would be the use of transplanting a drunken sot from his haunts of degradation and squalor to a home of culture and refinement? Unaccustomed to such intellectual surroundings, he would soon return to his filthy dive. The beautiful home would be hell enough for him. We may rest assured that life will sooner or later place us where we belong.

If you suffer from great physical weakness and nerve exhaustion, find out whether it is not caused by psychological phthisis. If you cannot determine this for yourself, have a good psychologist give you a thorough examination. The trouble with many people who are seriously affected by mental, emotional and psychical diseases is that they are unable or unwilling to diagnose their conditions. Frequently they resent vehemently the intimation that they may be suffering from such psychical disorders.

7. Envy

Envy represents a combination of the moods of anger and self-pity. Anger may be inspired by the thought that somebody else possesses the thing which we covet, and self-pity because we are deprived of the thing we desire to possess. Envy, therefore, consumes and wastes the body, mind and soul of its unhappy victims by the combined effects of psychological combustion and psychical phthisis.

8. Jealousy

Jealousy is a mixture of fear, anger and self-pity. We fear that somebody may take from us that which rightfully belongs to us, and anger results from such real or imaginary injury or injustice. Such fear and anger in turn provoke self-pity at the thought of the real or imaginary loss or injury. Thus we are torn alternately or all at once by the most powerful destructive emotions of the human soul. No wonder the victims of the "green monster" suffer the tortures of hell, that overcome by passionate resentment and the desire for revenge they commit unjust and cruel crimes against the innocent as well as the guilty. These terribly destructive emotions, even when seemingly justified, will never right a wrong, but only magnify its destructive effects on ourselves.

That which rightfully belongs to us can never be taken away from us. The majority of people do not distinguish between their real and imaginary possessions. Quite frequently the things which they believe they possess or desire to possess are, in reality, their greatest burdens and their worst enemies. That which we have earned through
faithful exercise of our natural capacities and powers, that is, our mental, moral and psychical characteristics, can never be taken away from us. They are the only possessions that will remain with us after the great transition. Nothing else besides this really belongs to us. We may enjoy the use of money, property and treasures of art for a day, a year or a lifetime, but they never become a part of ourselves and sooner or later we shall leave them behind us.

If a friend deceives and deserts us, it simply means that he was not our friend and the sooner we are rid of him the better for us in the long run. Our real friend, the one that belongs to us, is waiting for us somewhere. It is the same with all material possessions. The greater our possessions the more extravagant our wants and needs. People do not possess wealth, but are possessed and obsessed by wealth. The more simple the life, the less the wants and needs, and the less the fear of loss and deprivation. Those who are used to simple and economical ways of living rejoice in them. Those deprived of great wealth and comfort are appalled and discouraged by the loss of it. When we possess a thing we do not appreciate its value, but the moment we lose it we are overcome by unhappiness and resentment. Then why not do without it in the first place! Instead of wasting our vitality in spiteful resentment at our neighbor's prosperity, let us rejoice in his possessions and thereby make them our own.

If these things be true, then why allow ourselves to be torn by the destructive emotions of fear, anger and self pity because of real or imaginary loss of some ephemeral, or at any rate transient possession, which after all is not essential to the well being of the real man, the soul man; especially so when these discordant and destructive psychical emotions invariably result in mental and nervous breakdown and physical weakness, disease and premature death?

Diseases of the soul, created by perverted mental vision and lack of self control continue after death, afflicting the soul in the spiritual life just as heavily as on this side of the "Great Divide". while diseases of the physical body may terminate at death, abnormal conditions of mind and soul continue on the spiritual planes of life. Therefore our spiritual salvation, as well as physical health, depends upon the correction of our perverted mental vision and upon overcoming our lack of self-control.

Self-control is the master key to the solution of all our troubles and of all higher development on the mental, moral and spiritual planes of being. Flow to strengthen the power of will and how to overcome evil habits and to develop good habits I have described in the last chapters of this volume.

SECTION XXX

INSANITY, OR MENTAL, EMOTIONAL AND 
In the discussion of this subject I shall not follow the official classifications given in standard scientific works. These orthodox classifications are of little value to us, as they are based on outward manifestations or symptoms of mental disorders, while they do not take into consideration their underlying causes and true nature. In most instances they are merely Latin or Greek names for outstanding symptoms.

It is lack of understanding of the true nature and causes of mental and psychical disorders and lack of their rational treatment that accounts for the progressive increase of insanity, which keeps pace with advancing civilization in spite of the most determined efforts of medical science to stem the tide of this great danger that threatens the civilized nations.

A prominent physician at the head of one of the largest sanitariums of this country, in a public lecture, made the statement that at the present rate of increase in insanity all the inhabitants of this country would be insane at a certain future date. Happily this gloomy prediction will not come true, thanks to the rapidly increasing popularity of the nature cure idea.

I shall endeavor to treat the subject simply, as it has presented itself to me in actual experience, including under the term insanity all prolonged departures from the normal standards of thinking, feeling and acting.

The table on page 273 may help to elucidate this complex subject. It will be seen that I divide all forms of insanity into two main groups, the physical and the psychical. By physical, mental and emotional disorders I mean all those morbid mental conditions that originate in abnormal functioning or organic degeneration of the physical organism and particularly of brain and nerve matter.

MENTAL AND EMOTIONAL DISORDERS DUE TO PHYSICAL CAUSES (GROUP I).

A. Hereditary and Congenital Disorders

The physical-mental disorders are again subdivided into hereditary and congenital disorders. These may be of a functional or organic nature. They may result from abnormal prenatal influences of a mental or emotional nature; also from prenatal malnutrition, drug poisoning or trauma. A few days ago I examined a child four years old who had not yet learned to talk. The thyroid gland seems to be well developed and it is physically in normal condition. The frontal region of the head, however, is very low and the sides and the parietal parts of the skull above the ears are somewhat caved in.

The brown eyes of the child revealed three fully developed, heavy nerve rings, an extraordinary condition for a child of that age, indicating serious disorder of the nervous system. Both parents were in good physical condition before the conception of the child and have been ever since. The mother
told me that during pregnancy from beginning to end she had been tortured by great homesickness, mental depression and melancholia. This was the only adverse influence I was able to trace in the case. Possibly it had a harmful effect upon the intellectual brain area of which the speech center is primary and basic. Significant also in this respect is the depression in the parietal bones over Brocha’s convolution, the location of the speech center.

A grown cretin and idiot whose eyes I examined showed in the brain region a very heavy scurf rim. The mother, during pregnancy, had taken enough calomel for liver trouble and constipation to produce the symptoms of salivation several times. The mercury sign was distinctly visible in her eyes. In all cases of so-called hereditary syphilis it is the mercury, salvarsan, arsenic, iodine, potassium or other drug poison, not venereal disease, which produce the congenital defects in the

---

**Mental and Psychic Diseases - Varieties and causes**

**Group I**  
Mental & Emotional Disorders due to Physical causes

- **A** Hereditary and Congenital defects
  - Functional or Organic
  - 1. Accidental injury
  - 2. Autointoxication resulting from:
    - External violence
      - Exposure
      - Starvation
    - Pathogenic encumberances
      - Inflammation
      - Fever
  - 3. Alcoholic poisoning
  - 4. Drug intoxication
    - Mercury
    - Iodine
    - Quinine
    - Bromides
    - Coal tar Products
    - Other toxic substances

- **B** Functional disorders caused by:
  - 1. Accidental injury
  - 2. Autointoxication resulting from:
    - External violence
      - Exposure
      - Starvation
    - Pathogenic encumberances
      - Inflammation
      - Fever
  - 3. Alcoholic poisoning
  - 4. Drug intoxication
    - Mercury
    - Iodine
    - Quinine
    - Bromides
    - Coal tar Products
    - Other toxic substances

- **C** Organic degeneration of brain and nerve matter caused by:
  - Sclerosis
  - Gummata
  - Tumors
  - Abscesses
  - Hemorrhages
  - Paralysis

**Group II**  
Mental & emotional disorders due to psychical causes.

- Subjective psychism due to lack of self control caused by:
  - 1. Negativeness
    - Hypersensitiveness
  - 2. Abnormal development of spiritual senses resulting in clairvoyance/clairaudience
  - 3. Hypnotic control
  - 4. Mediumship
  - 5. Obsession Possession

- Weakening physical habits
  - Mental & emotional disturbances peculiar to the periods of:
    - Pubescence
    - Adolescence
    - Climacteric
    - Sexile Decline
  - Destructive mental habits & Emotionalism
    - Stubbornness
    - Fear
    - Worry
    - Melancholy
    - Anger
    - Introspection
    - Self pity
  - Exaggeration of good habits and emotions
    - Religious Exaltation
    - Over-concern
    - Self condemnation
    - Over scrupulosityness
    - Morbid-altruism
  - Vicious habits
    - Alcoholism, Sexual perversion
  - Hypnotic control
    - Passive submission
It is a fact that syphilis is not communicated to a nursing child through the milk. Much less is it possible that the disease is conveyed from mother to child prenatally. Nature does her best to protect the young life against adverse influences. But Nature is powerless to prevent the introduction of virulent poisons into human bodies by the disciples of pseudo-science.

Serious injuries to the abdomen of a pregnant woman may also cause congenital nervous or mental derangement or physical deformity of the offspring. A few weeks ago we examined in our open clinic a child a few months old whose lower ribs on one side were badly caved in. The mother had a serious fall during the last month of pregnancy. The deformity is rapidly yielding to manipulative treatment.

**Congenital Deficiency of the Ductless Glands**

Congenital deficiency of the thymus and thyroid glands is responsible for most cases of cretinism, idiocy and backward development. Allopathic medicine endeavors to overcome these defects by the administration of thymus or thyroid extract. This, however, is only palliative. While these animal extracts may serve to a certain extent as a substitute and may stimulate the physical and mental development of the child, still the administration of these artificial preparations tends to retard the natural development of the glandular structures. Whenever the administration of the thyroid extract is interrupted, the improvement ceases and there is a strong tendency to retrogression. After all, these extracts artificially prepared from animal bodies are not congenial to the human organism and their constant administration tends to create abnormal conditions. This has been observed in many instances.

Much better and more permanent results are obtained by natural management and treatment. All the tonic influences of the various methods of natural treatment especially massage and neurotherapy-manipulation of the nerve centers which supply the ductless glands tend to develop the defective organs in a perfectly natural manner. We have thus treated and cured many little patients suffering from congenital malformations, backward development, cretinism, defects of the sensory organs and idiocy.

**B. Functional Disorders**

1. **Accidental Injury**

Functional disturbance may be caused by external violence such as concussion of the brain from blows on the head or from falls, etc. Spinal analysis frequently discloses lesions, particularly in the cervical region. The impingement on the blood vessels and nerves by suck bony displacements or contractions of connective tissues may produce mental and nervous disorders which will abate or disappear when the lesions are corrected by proper manipulative treatment.
When mental or nervous disorders result from fractures or indentations of the skull, the fractured bones or splinters pressing upon the brain matter must be removed by surgical treatment.

2. Autointoxication

Many forms of functional mental disorders are caused by systemic poisoning resulting from the accumulation of morbid matter and poisons produced in the system, such as acids, alkaloids, ptomaine and xanthins, which we designate collectively as pathogens. These morbid materials circulating in the blood may unduly exalt or depress the normal activities of the brain and nervous system. For instance, the acids of phosphorous have a powerfully irritating and stimulating effect upon brain and nerve matter, giving rise to nervous irritability, insomnia and hysterical manifestations, while carbon dioxide (CO$_2$) has a benumbing, depressing effect.

The normal structure and functioning of brain and nerve cells depends upon the quantity and quality of the blood supply. Therefore the normality of mental and emotional functions depends to a large extent upon the purity and normality of the vital fluids. If the blood stream which feeds the brain and nervous system is saturated with gluey, mucoid and gaseous materials, the mental and emotional activities will be sluggish and phlegmatic, resulting in impairment of memory and of the reasoning faculties.

Excessive acid formation in the system may result in earthy deposits in the walls of the blood vessels, narrowing their lumen and obstructing the circulation, thus causing so called hardening of the arteries with its attendant depressive effects on brain functions, tendency to hemorrhages, embolism, etc.

As we have learned in our study of dietetics, practically all pathogenic materials are formed by the excessive intake of starchy, protein and fatty foods because the elements composing these foods are electromagnetically negative and therefore pathogen forming substances. These foods at the same time are very deficient in the positive acid binding and eliminating alkaline mineral elements.

The prevention and treatment of this class of disorders is, therefore, largely dietetic and must consist in reducing the protein, starchy and fatty foods and substituting foods rich in the positive alkaline salts of sodium, potassium, calcium, magnesium and iron. Other efficient methods for eliminating pathogenic materials are hydrotherapy, massage, neurotherapy, air and sun baths, proper breathing and curative exercises, homeopathic remedies, etc.

3. Alcoholism

Alcoholism is another prolific cause of functional disorders of a toxic character, producing gradually degenerative changes in the tissues of the body, especially in the liver, spleen and kidneys. In advanced stages it causes degeneration of brain and nerve matter and may result in various forms of
The symptoms of alcohol poisoning cover a wide range, from simple nausea to violent delirium, coma and death.

Alcoholic poisoning may result from the use of distilled liquors, such as whisky and alcohol, or of fermented liquors, such as wines, beer, ale, etc. Many patent medicines and medicinal tonics owe their stimulating effects to the large percentages of alcohol that they contain. Meat eating, coffee drinking, smoking and the use of habit-forming drugs all create a craving for alcohol, and vice versa.

We find in our work that we cannot permanently break our patients from the use of one stimulant unless they give up all other stimulants. Many times we have weaned patients from meat eating, smoking, coffee toying, the use of alcoholic liquors and habit forming drugs, and after their systems had been thoroughly purified from these poisons all craving for them disappeared. Occasionally one would again fall victim to the old, destructive habits.

Inquiry into the cause for backsliding usually brings out confessions like the following: "Oh, doctor, I felt so fine that I thought just a cup of coffee" or "just one or two cigars a day would not hurt me, but I find that my will power once weakened, I could not resist the temptation of indulging more freely. Every time I used a stimulant it seemed to create a craving for another one. When my system was in a purified condition, a piece of meat seemed to stimulate me more than once did a glass of whisky, but the taste of meat created a craving for a cup of coffee or a cigar, and so on until I became once more a slave to all the old habits and now I seem to be deeper in their bondage than ever before." "Give the devil your little finger and he will soon have the whole fellow in the bargain."

When the body is thoroughly saturated with meat poisons, caffein, uric acid, drug poisons, etc., a dozen drinks or cigars a day, more or less, make little difference; but when the system is purified of these poisons and in normal condition, even small amounts of any kind of stimulant will affect the nervous system profoundly and excite a craving for yet stronger stimulation.

That alcoholism is a hereditary disease has been proved beyond a doubt. This should be a matter of grave consideration for those who intend to assume the responsibilities of parenthood.

Symptoms: The symptoms of alcoholism, like those of all other diseases, manifest in the acute and chronic forms. The light drinker awakens in the morning in a morose and irritable condition. He has no desire for food and is unfit for the work of the day until he has had his "eye opener". At a later stage of the disease the nausea develops into vomiting and the indigestion becomes more pronounced and chronic. Constant hyperemia of the stomach, liver and spleen are followed by gradual atrophy.
The drinker of whisky develops 'the shrunken, hobnailed liver; the liver of the habitual beer drinker becomes greatly enlarged; sometimes weighing from twenty to forty pounds, but later on it also shrinks.

The last stages of alcoholism are marked by malnutrition, emaciation, the loss of memory and intellectual faculties.

Alcoholic poisons gradually benumb, paralyze and destroy the best qualities of the body, mind and soul, until the victim falls to the depths of physical, mental and moral degradation.

All drug cures for this terrible disease are of questionable value. They may create a temporary revulsion for alcohol, but at best this is another case of Beelzebub against the devil. The drugs used in these cures have a bad effect upon the system and when the sedative effects of the drug treatment have lost their hold upon the patient, he relapses into the old, destructive habits. Exactly the same is true of hypnotic treatment for destructive habits. It is at best only temporarily suppressive. Hypnotic control still further weakens the will of the subject. He temporarily abstains from liquor, not of his own accord, but compelled by the dominating will of the hypnotist. When this begins to wane he has less control over his cravings than before.

In this connection it must be remembered that a person cannot be hypnotized unless his own reason, will power and self-control are temporarily suppressed and completely in abeyance. If this takes place repeatedly, paralysis of these highest faculties and capacities of the mind and soul becomes permanent and the victim of hypnotism degenerates into the abject slave of every stronger influence. He becomes a negative weakling and drifter, frequently ending in an insane asylum.

The only possible and permanent cure of alcoholism and of drug habits lies in a complete regeneration of the individual through natural methods of living and of treatment. If the patient is in the advanced stages of alcohol-jam, afflicted with organic diseases of the stomach, liver, kidneys or heart and subject to attacks of delirium tremens, it may be necessary to wean him gradually from the effects of the poison by allowing him graduated doses of alcohol, morphine or whatever the habit forming poison may be.

An attendant must administer gradually decreasing doses at increasing intervals of time. The strength of the poison at the same time may be reduced without the knowledge of the patient. In many instances we have given such patients injections of pure distilled water when they imagined they were still getting strong doses of morphine. In such cases the power of suggestion frequently shows us its wonderful effects. Not long ago a patient came to us from a neighboring hospital. An operation had been performed on one of his limbs. It was then kept in a plaster cast for four months. The only remedy they had in the hospital for the terrific pain following the operation was morphine. When he was brought to our institution he was using as high as ten grains a day.
Under the natural treatment the pains gradually abated and within a few weeks we succeeded in reducing the morphine to minimum doses, but whenever we refused to give him an injection he would yell at the top of his voice, claiming that he could not stand the pain and could not sleep. Pains did not trouble him and he was able to sleep when we injected distilled water. The water did the work just as well as the morphine as long as he was under the impression that morphine was being administered. We had to keep up the deception for three weeks, gradually decreasing the number of injections until he became convinced that he could do without the "morphine".

The active treatment of alcoholism must include everything that is good in natural methods. Of primary importance is a strict vegetarian diet, alternating between raw food, dry food, milk diet and fasting regimen. Tonic cold water treatments, massage, Swedish movements, neurotherapy, curative gymnastics, air and sun baths and everything else conducive to a thorough regeneration of the system must be applied systematically. Such patients require constitutional treatment.

During the first stages of treatment, while the victims of drug and liquor habits are helpless and without will power and self control, they need constant attendance and careful nursing day and night. The poison to which they are addicted must be administered in gradually diminishing doses at lengthened intervals and, unless confined in a padded cell, they must be guarded against escape or self-inflicted injury and suicide. When the system of such a patient has been thoroughly purified and regenerated, when he has become accustomed to and thoroughly enjoys a vegetarian diet, the craving for liquor, tobacco or drugs will have disappeared and will not return unless he willfully indulges in former habits.

We have proved in many cases that such a thorough purification and regeneration of the system is a much better guarantee against relapses than all the poison cures in existence.

Not the least potent among the regenerative influences of the Natural Therapeutic treatment are the daily lectures and private consultations through which the patient becomes acquainted for the first time in his life with the natural laws underlying the processes of health, disease and cure, which he must obey in order to attain perfect health and the greatest possible capacity for enjoying the pleasures of life and the highest efficiency in the performance of his share of the world's work. He now becomes aware that these highest and finest achievements of human life cannot be attained through any form of self-indulgence. Having learned his lesson through the great contrast between utter misery and degradation and the enjoyment of perfect health, he is willing to pay the price of self-control in the future.

The best of drug treatment, while it may break the alcohol or drug habit more or less permanently, never leaves the system in the purified and regenerated condition such as results from natural treatment, which alone insures perfect
health and the complete enjoyment of the good things of life.

4. Drug intoxication

Alcoholism has been made the scapegoat for the increase in insanity among civilized nations and for the major part of defective heredity. Its influence, bad as it is, has been greatly overrated. This will be proved positively after national prohibition has become an accomplished fact in this country. Fully as destructive have been the effects of poisonous drugs, especially of mercury, iodine, quinine, arsenic, strychnine, bromides and coal tar preparations.

Alcohol is in a way congenial to the human organism. It is manufactured in small quantities in most human bodies as a product of sugar fermentation in the intestines and is burned up in the system like other fuel material. It is probably for this reason that alcohol is not shown in the iris by a characteristic sign of its own.

Nicotin and caffein do not show in the iris because they are chemically closely related to the uric acid group and are therefore congenial to the system. This indicates that these xanthins are eliminated with comparative ease.

Whenever an habitual alcoholic quits taking the poison its effects are without great difficulty overcome by natural methods of living and of treatment. Poisonous drugs however, have a strong tendency to accumulate in those tissues of the body for which they have a special affinity, there to act as powerful irritants and poisons, creating many of the most destructive chronic diseases.

The destructive effects of drug poisons are fully described in Iridiagnosis, Vol. VI of this series.

Mental disorders caused by poisonous drugs are more difficult to cure than any other forms because they readily result in organic degeneration. (See Quinin, Mercury, Iodin, Coal Tar Products, etc. Vol. VI.)

C. Mental and Emotional Disorders Due to Organic Degeneration of Brain and Nerve Matter

All functional mental disorders if prolonged by neglect or intensified by suppressive drug treatment may result in organic degeneration of brain and nerve matter, creating such conditions as paresis (softening of the brain), sclerosis of the spinal cord, anterior poliomyelitis, etc. It is evident that cures are much more difficult or may become impossible when the stages of organic degeneration have been reached.

A few cases of organic insanity are caused by injury to the brain, but the great majority are due to the action of morbid matter and paralyzing or destructive poisons on the brain. These poisons may have been generated in the body by unnatural methods of living. They may be alcohol, nicotin, caffein or destructive acids and paralyzing alkaloids which are the waste products of faulty protein and starch metabolism.
Morbid encumbrances and organic decay are frequently due to the suppression of scrofulous, psoric and syphilitic diseases. About sixty percent of all organic cases, however, are due to the ever-lengthening array of destructive drug poisons such as mercury, iodin, quinin, arsenic, bromin, acetalonilid and other coal tar products.

Organic defects may be created in the following manner: Earthy waste matter forms deposits in and clogs and hardens the minute blood vessels of brain and nerve centers. Xanthins and alkaloids of the uric acid type, or destructive drug poisons, cause obstruction, abnormal changes, decay and actual destruction of nerve and brain matter.

To this group of organic insanity belong all nervous and mental disorders classed by the old school of medicine under locomotor ataxia, paresis, dementia paralytica, senile dementia, etc.

This entire range of diseases is looked upon by the medical profession as incurable. Nevertheless, we constantly prove in our practice that all of these types of disorders can be alleviated and a large percentage of them cured by natural methods of treatment, provided there is sufficient vitality left in the organism to respond to treatment and provided also that actual destruction of brain and nerve matter is not too far advanced.

The medical treatment of these disorders consists almost universally in the administration of mercury, iodin, arsenic, strychnin, salvarsan and coal tar products. Diagnosis from the iris, however, and the history of cases of this type, reveal the fact that almost without exception these diseases have been produced by the absorption of these same poisons earlier in life.

How, then, can such cases be cured by the poisons which produce them? Is it any wonder that medical science calls them "incurable" when too much drugging is all that ails them? Is it any wonder they improve under Christian Science or any other non-suppressive treatment? Every case of locomotor ataxia, paralysis agitans and paresis which has come under my observation has revealed the signs of drugs, and inquiry into the history usually confirms the drug records in the iris.

It takes mercury from five to sixteen years to work its way into the brain and spinal cord—then its destructive symptoms begin to manifest. What is commonly called secondary and tertiary syphilis is nothing but mercurial and iodin poisoning. Syphilis and gonorrhea in themselves are easily curable by natural methods of treatment. If properly treated, without poisonous drugs, these taints can be completely eradicated from the system within four or five months' time. Not a single case treated by us from its incipiency, that is before suppressive treatment had been given, ever developed any secondary or tertiary symptoms or hereditary disease in offspring.
The subject of defectives and venereal diseases has been fully treated in "The Black Stork".

MENTAL AND EMOTIONAL DISORDERS DUE TO PSYCHICAL CAUSES (GROUP II)

The second main division of our diagram deals with psychical disorders. Under these we classify forms of insanity due to mental, emotional and psychical influences. All mental and emotional disorders may finally result in various forms of abnormal psychism such as hypersensitiveness, negativeness, clairvoyance, clairaudience, hypnotic subjection, mediumship, obsession and possession.

Every form of perverted mentalism such as stubbornness, fear, worry, hypochondria, anger, fury, rage, jealousy or self pity may become permanent forms of destructive emotionalism. In our practice we are daily more and more impressed with the fact that any form of abnormal thinking and feeling may easily develop into the most terrible depressive or emotional insanity.

Mania is frequently merely a natural tendency unduly exaggerated through loss of self-control. If parents could be made to realize that their fond indulgence of a child's selfishness, indolence, willfulness, irritability and temper may develop into the worst forms of nervousness, hysteria and insanity, they would employ the best means at their command to stimulate, educate and strengthen the will power and self-control of the child. In the weakening and loss of self-control lies the root of psychical disorders; in its restoration, the cure.

Paranoia, Monomania, Fixed Idea

Forms of mental diseases classified by medical science under these heads are largely the result of destructive autosuggestion.

I have not been able to find a better illustration of mental and emotional processes than the phonograph and kinematograph. The gray matter of the brain corresponds to the record cylinders in the phonograph or to the films in the moving picture machine. These plastic materials receive, register and retain impressions of sound and passing scenes and reproduce them automatically. So, also, the gray matter of the brain receives, registers and retains impressions from the outside world coming through the sensory organs and also impressions of thoughts and emotions generated in the mind of the individual. After these records in the brain matter have been established, they repeat themselves spontaneously or at the call of the will.

All our distinctly human physical and mental capacities and functions have been created in that way. We had to make the centers or records in the motor or Rolandic area of the brain before we could walk or use our limbs for any other purpose. We had to create centers in Brocha's convolution in the frontal brain for every word we have learned to speak in our own or in any foreign language. In like manner we had to create
molecular groupings or brain centers for everything we have gained in the acquisition of knowledge or in the execution of manual labor or artistic productions. Before we can solve a problem in arithmetic, acquire dexterity in the handling of a tool, play the violin or any other musical instrument, we must first establish the necessary centers in the gray matter of the cortex. After these molecular groupings in brain matter have been created, they work almost spontaneously and may control the physical organism and the mentality through what we call habit.

It took many months of laborious effort to create in Brocha's convolution the molecular groupings for the pronunciation of the words "papa" and "mama" and of other words in an infant's vocabulary. But after the centers were once established, speech flowed freely at the slightest volitional impulse. Many months of laborious and persistent efforts were required to develop the centers in the brain area for muscular movement and coordination before we could make the first tottering steps, but after these centers in the area of Rolando and in the cerebellum were established the legs responded to the slightest impulse of the will.

In similar manner all thinking and feeling impresses its paths, grooves and records in the plastic gray matter of the brain, and after having been firmly established these records of thought, ideas, feelings and memories repeat at the volition of the ego, or they may play their tunes spontaneously. Memory, habit, character, individuality, the subconscious or subjective mind, are made up of these records in the gray matter of the brain. These highly interesting matters are more fully treated in Vol. IV, Natural Eugenics.

Whether our memories and our habitual states of thinking and feeling are of a pleasant, cheerful and happy nature, or whether they are discordant, irritable, morbid, melancholy, unhappy, spiteful, critical, jealous or destructive in any other way, depends upon the kind of records we have made in the past, that is, the kind of thoughts and feelings we have entertained and allowed to impress themselves upon the plastic gray matter of the brain. Our future mental, emotional, moral, spiritual and psychical characteristics will depend upon the records we make from this moment on.

When I explain these fundamental principles of psychology and mentalism, people ask, "How can I prevent unpleasant thoughts and feelings from entering my mind!" There lies the root of the trouble. People have never been taught that they have the power to control their thinking and feeling, as well as their eating and drinking. If these fundamental laws and principles of mentalism and emotionalism were impressed on the child mind from the awakening of understanding, what an amount of unhappiness, mental degeneracy and insanity might be prevented!

While conversing with a friend about the terrible fate of the victims of autosuggestion, hypnotism, mediumship, obsession and other forms of subjective psychism, she remarked, "It seems incomprehensible why a kind Providence allows
innocent and naturally good people to drift into these terrible conditions which must lead to indescribable suffering and final extinction of the individuality."

I answered to this, "Somewhere, some time in the history of these individuals they drifted into abnormal ways of thinking and feeling, brooding over real or imaginary troubles, fear of impending poverty, of persecution or misfortune, fear of eternal damnation, of having committed the unpardonable sin or of other religious delusions.

These fear records multiplied until they filled the mind to the exclusion of everything else and then played their direful tunes incessantly day and night, creating a living hell for the unfortunate victim of his own mental obsession. Others in similar manner drift into negative conditions of thinking and feeling, which make possible control and obsession by external influences and vicious intelligences in or out of the body."

These victims of destructive autosuggestion begin to fear, worry and brood about something. There may be some reason for it, or the thing dreaded may be entirely imaginary-nine times in ten it is. This occurs usually among people who have not enough real work in their lives but too much time to think and brood. Every time they indulge in this sort of fear thought they impress it more deeply in the plastic gray matter of the brain.

One idea sown in the subconscious mind keeps on growing and multiplying until it crowds out everything else. Thus arises the fixed idea, or monomania. The unhappy victim of his own delusion is no longer capable of thinking or feeling anything else. It fills his mind entirely, shows in his behavior and in his gloomy, melancholy features. Hundreds of thousands of people in this United States are thus slowly but surely creating for themselves the worst hells in the universe without realizing their danger, and nobody raises the danger signal because people do not understand the laws of destructive mentalism.

I have come into contact with many of these unfortunates whose minds were filled with just one kind of discordant, destructive records playing their dismal tunes by day and night, without relief or intermission. Just now I have under observation a man twenty-eight years of age who has worked himself into such a deplorable condition. He belongs to a wealthy family, is well educated and has had every possible opportunity to make life a success. A few yearns ago he began to brood and worry over an unhappy love affair. His friends tell me the severing of this attachment was in reality most fortunate, because the object of his affection was not of good moral character, and according to her own confession tried to marry him only for his money. Notwithstanding this, he allowed the matter to occupy his mind to the exclusion of everything else. He imagined that he had wronged the young woman beyond the possibility of atonement. This brought up the idea that he was unworthy of respect and unfit for association with his fellow beings, and this in turn led to more
introspection and seclusion, until these melancholy, morose and self accusatory ideas filled his mind so completely that he tried in various ways to end his misery by suicide.

In spite of all this the man is endowed with splendid intelligence. Even during this mental obscurcation he was able to vanquish some of the best checker and chess players in Chicago. Only a few days ago he mentioned to me from memory the telephone numbers of a dozen firms he dealt with two or three years ago. The telephone book proved his memory absolutely correct. Still, long continued and persistent explanations and persuasion have so far proved inadequate to lift his dismal mental obsession. His troubles undoubtedly originated by making the wrong kind of brain records.

People do not realize that this sort of fear and worry thought is a form of destructive self-indulgence just as surely as is overindulgence in alcoholic liquors or in habit creating drugs. They have never been taught that destructive mentalism and emotionalism may be prevented by the exercise of will power and self control just as easily as alcoholism or the cigarette or drug habits.

**Treatment of Monomania**

These forms of fixed idea or monomania cannot be successfully treated at home. Old surroundings, relatives, friends and accustomed scenes and objects constantly call up the old brain records and cause them to play their dismal tunes. Change of environment—new people, new sights, new ideas—is absolutely necessary to create new brain records and to throw the old ones into disuse and oblivion. We endeavor to hasten the mental regeneration by arousing interest in new ideas and higher ideals, by instilling new faith and the will to be well in place of the old doubt and despair thought.

We have found that the best way to accomplish this is through daily health talks in which we explain to our patients how physical and mental ills are created through violation of Nature's laws of thinking, feeling, breathing, eating, drinking, bathing, etc., and how they must learn to help themselves by complying with Nature's laws in their habits of living.

Nervous and mental patients who would resentfully reject any helpful suggestion in private consultation will allow the ideas propounded in a public lecture to sink into their inner consciousness without arousing antagonism and repulsion.

Hand in hand with change of surroundings and suggestive treatment must go the purification and upbuilding of the physical body, as outlined in this volume.

About a year ago a woman came to us for treatment who was firmly convinced that she had committed the unpardonable sin against the Holy Ghost, that she was damned to hell for all eternity and that there was no possibility of salvation for her. The unhappy condition of her mind may be easily imagined. For four months she exerted all
her strength to refuse my helpful arguments and suggestions. Like most of these people she argued with the ingenuity of an accomplished lawyer trying to prove that she was indeed utterly depraved and lost, while in reality she had been the best and kindest of human beings all through her life, until these unfortunate delusions overwhelmed her.

About two months after she had left for home I received a letter from her which contained the following passage:

"Toward the end of my sojourn in your institution I began to realize that you were right and that I was altogether wrong in my foolish imaginings through which I had created for myself the worst imaginable hell of mental and emotional suffering. But through long continued habit and stubbornness of mind I was not ready nor willing to acknowledge my fault. But after I arrived home and had time and leisure to think matters over I became fully conscious of the absurdity and terrible consequences of my mental aberration. Now I have found my old self again and the dreadful delusions which obsessed and threatened to destroy me seem like a bad dream or dreadful nightmare."

**Psychic Insanity or Abnormal Psychism**

The majority of psychical mental disorders are induced by negative, sensitive conditions on one or more planes of being. I mean by this that physical, mental and moral vigor and resistance have become weakened in some way or another and that as a result, reason, will and self control are benumbed and paralyzed to such an extent that the individual comes into abnormal contact with the lower spiritual planes of existence and lays himself open to hypnotic control by other intelligences in or out of the physical body.

The paranoiac, the delusional maniac and the true medium are frequently hypnotically controlled by vicious intelligences on the physical or spiritual planes of being. The drunkard in delirium tremens actually sees things. The snakes and other horrid creatures which terrify him are not altogether hallucinations of a distorted imagination. In his case the physical organism and its sensory organs, under the deadening influence of alcohol, have become so benumbed and paralyzed that the senses of the spiritual body are abnormally active. In other words, the victim of alcohol becomes clairvoyant on the lowest plains of spiritual life—the hell of the theologians.

Our physical material plane of life corresponds, as far as location in space is concerned, to the lowest spiritual plane, the astral plane of the theosophists, and therein lies the awful danger of premature and abnormal psychical development through negative, subjective processes. All such experiments are extremely dangerous as long as the individual is bound by his heavy physical body and by heavy spiritual gravity to the lowest plane of spirit life.

The doctors who have lately "weighed the soul" by observing and recording the loss of weight at the point of...
death were right in their conclusions. The spiritual body, mentioned by Paul and visible to the seer, is material just as is the physical body, and although this spiritual counterpart of the physical body consists of matter in a very rarefied form, still it occupies space and has some weight.

Those who, by a weakening of will power and by subjective, negative processes of psychic development rashly expose themselves to psychic control and abnormal quickening of the spiritual organs of sense, come in contact with the slums and vicious inhabitants of the lowest planes of spiritual life.

To the religiously inclined who doubt these statements I would say that if these things are untrue, then the New Testament is false from beginning to end. If abnormal psychism and obsession was a fact in Nature nineteen hundred years ago, it is a fact today.

To the materialistic, skeptical scientist I would adapt the quotation and bid him remember "there are really more things in heaven and earth, my medical Horatio, than have been dreamed of in thy philosophy". Only he who has sincerely and earnestly investigated and tested these subjects has a right to speak and judge.

When I took "incurable paranoiacs" from a state insane asylum, the doctors in charge smiled at my presumption and informed me that never yet in the history of the institution had a case been cured. Yet we have permanently cured several such cases within four to twelve months' time.

It is not to be wondered at, however, that these patients are incurable under the conventional treatment when we stop to consider that insane asylums are veritable "hells on earth", where ignorant and vicious spirits congregate to obsess and vampirize defenseless victims. The latter are rendered more negative and subjective by idleness, improper diet, solitude, confinement, constant communication with other insane, by the vicious spiritual atmosphere, and by the paralyzing influence of sedative and hypnotic drugs which are negative in their effects on the human organism.

There are those who endeavor to restore lost self-control by "hypnotic suggestion", which, however, is a misnomer. An able writer on this subject draws the following distinction between suggestion and hypnotism:

"It is safe to say that in its most common acceptance the word [suggestion] is intended to mean a deferential method of calling the attention of one person to the subject matter in the mind of another and inviting favorable consideration of the same.

"For some reason, quite inconceivable at this time, the word has become inseparably connected and associated in thought with the subject of hypnotism. By a sort of tacit agreement or understanding, as it were, among writers and students generally, it has come to include almost, if not quite,
all the means and methods by and through which a hypnotist impresses his own thoughts, impulses, desires and will upon the consciousness of his subject.

"But it must be borne constantly in mind that in exact proportion to the depth or intensity of the hypnotic state the hypnotist controls the will, voluntary powers and sensory organs of his subject. Under these conditions the subject, to the extent that hypnosis exists, is deprived of the power of independent choice, without which the word 'suggestion' is entirely meaningless to him.

" Indeed, every thought, every impression, every impulse of the will projected by a hypnotist upon the consciousness of his subject during the hypnotic relation has, just as far as the hypnotic process is able to carry it, the force and binding effect of a definite and inviolable command. It is not presented to the subject for his consideration as an independent self conscious and rational intelligence possessing discretionary powers. It is not submitted to the rational judgment of the subject at all. It is not offered upon the theory that it may possibly be rejected. On the other hand, it is forced upon him under conditions which, according to the laws of Nature, make its rejection an impossibility.

"And yet, notwithstanding all this, it is called 'suggestion' by learned men who are wise enough to instantly discover many a less conspicuous error."

Careful scientific investigation has demonstrated that hypnotism may not only produce insanity and physical death, but that it seriously interferes with the normal development of mind and soul and entails evils far greater than mere physical debauchery. In fact, hypnotism is debauchery of mind and soul.

It is not to be questioned that hypnotism practiced in a helpful spirit may produce temporary results which seem in a measure to justify its use, but if these be observed in their unfolding it will be found that there has been no actual cure; that the results were merely the effects of a brain paralysis and the substitution of the will of the operator for the will of the victim. In other words, hypnotic treatment, like that by drugs, is suppressive, not curative.

There is a single consideration which of itself should deter any self respecting and prudent person from submitting to hypnotic control. This process involves the temporary subjection and abeyance of reason, will power and self control of the subject. With each repetition, these highest attributes of the soul become more benumbed and paralyzed. This not only prevents the development of the higher faculties, capacities and powers, but starts the victim of hypnotic control on the downward road of mental and moral deterioration and retrogression. Such a person becomes an easy prey to any outside influence that may desire to control him for good or evil.

Those who are regularly experimenting with this dangerous
power, believing that they are accomplishing beneficial results, should ask themselves if they have a right to extinguish self consciousness and to usurp absolute control over the mind and soul of another individual when this means criminal intrusion upon the sacred rights of individual consciousness and personality for the sake of merely temporary and doubtful benefits.

It is our highest and most solemn duty to maintain the waking consciousness and to guard the citadel of our being at all times against intrusion and control by outside intelligences. Any process which progressively weakens the victim's control over his own acts is in violation of the primary law of individual life the law of moral and personal responsibility.

Reason, will power and self-control are the soul attributes which distinguish the human from the animal. Take these away and there is nothing left but an idiot or a lunatic. When these highest qualities of the human soul are permanently benumbed and paralyzed through the hypnotic process, the individual sinks below the animal plane, because he has not even animal instinct to guide him. This is soul murder.

I began to realize the destructive nature of hypnotism and mediumship when I was studying Nature Cure in Berlin. At that time I also took a course in "Suggestive Therapeutics" under Jacques Groll, at that time the most celebrated hypnotist in Germany.

My fellow students appeared to enjoy the abject submission and helplessness of our clinical subjects when under hypnotic control, but from the beginning the pitiable condition of these wretches, deprived of reason, will and self-control, was revolting to me. Although endowed to a marked degree with the power to exert hypnotic control, I decided there must be other less harmful methods of curing human ailments and resolved never to employ subjective methods in any form whatsoever.

There is no delusion more fatal than that encouraged by certain church organizations engaged in the work of psychic healing, namely, that will power can be restored and strengthened by hypnosis-the very process that destroys it more surely than any other known agency, a process which is the greatest crime which can be committed against a human being.

We now come to the consideration of subjective psychism, in its various phases closely related to hypnotism. These states all have their incipiency in negative physical and mental conditions. By a negative condition we mean weakness, lack of resistance, susceptibility and submission to outside influences.

Prominent factors in producing negative physical and psychical conditions are hereditary tendencies, debilitating diseases, drugs which exert a negative hypnotic influence upon the organism, a negative diet, vicious habits, such as alcoholism, sex perversion, etc.
Habits not vicious, but which have been indulged in to the extent of jeopardizing self control, may lead to subjective psychism. Among these are religious emotionalism, over scrupulousness, concern about the future, morbid altruism, in fact any good habit exaggerated to a degree involving loss of equilibrium.

Again and again physicians hear from the patient this complaint, "It is not that I like doing these things; I abhor and detest the very thought of them. A foreign influence seems to come over me and to control me. I feel as if it were another person." Indeed, it often is. All habits carried to a point producing loss of self-control open the door to control by outside intelligences having the same tendencies. Yet even so, hypnotism and the séance room may accomplish more harm in a few "sittings" than evil habits during a lifetime.

Hypnotic control depends upon the temporary paralysis of reason, will and self-control. If persisted in it may result in the permanent loss of these capacities and powers that distinguish man from the brute.

Under abnormal psychism I include all phases of psychism, from mere sensitiveness and awareness of conditions on the spiritual planes (clairvoyance, clairaudience, etc.) to actual obsession, which is the hypnotic control of an individual in the body by an intelligence outside of the body. Such control by a spiritual intelligence may result in complete possession of the physical organism by the obsessing influence.

Not long ago I received from a distance a manuscript describing the author's experience in developing mediumship, from the time when she began to receive strange vibrations and to be impressed by peculiar sensations until she heard voices and came in actual contact with her "controls".

These experiences became very annoying and interfered with her daily occupations as well as with rest and sleep. She begged her tormentors to leave her and threatened to disclose her true condition. They laughed and told her if she did she would be adjudged insane and would be confined in an asylum.

When her condition became unbearable she related these experiences to her husband and to the family physician; the latter shook his head and left a prescription for her "nerves". A few days later, her husband took her for a walk and with her entered a large building. Presently she found herself before an assemblage of physicians and nurses and was asked to tell her story. After she had done so the doctors agreed that she was suffering from delusional insanity and committed her to the institution.

In the manuscript she tells a piteous story of her experiences. During two years she was confined in three different asylums. "All this time," she says, "I was as sane as ever in my life, but the mere mention of my psychic experiences was sufficient to commit me."
People no more insane than we are have been tortured by experiences which in many instances they are afraid to tell their nearest friends, lest they be committed to the insane asylum.

Psychic exposure is brought about by a weakening of the physical body and its magnetic envelope, sometimes called the aura. The physical body and its magnetic envelope form the protecting wall dividing us from contact with the astral plane and the lower spiritual spheres. If between the room where I am sitting and the adjoining one there were a heavy brick wall, I should be unconscious of what is transpiring on the other side; but if the partition consist merely of wood and glass, I apprehend every sound and can hear distinctly the conversation in the other room. Thus it is with a person whose protective physical and magnetic envelopes have been weakened and attenuated to such an extent that the spiritual senses have become abnormally active on the lowest spiritual planes coexistent with our earthly plane.

From what I have said it becomes apparent that the cure of abnormal psychism cannot lie in solitude, confinement, idleness, sedatives nor hypnotics, either in the form of drugs or of "suggestion", but in the application of natural tonic treatment. Fundamental is the right diet, rich in positive dairy foods and in positive vegetable foods that grow in and near the ground. Massage and neurotherapy are important because they stimulate in a natural manner the dormant nerve centers. Hydrotherapy and open air baths stimulate and invigorate the circulation and the vital activities of the skin. Daily physical culture drills, particularly the psychological exercises, not only strengthen the body but teach coordination of mind and muscle, thereby exercising in a most effectual manner will power and self control.

Medicinal treatment, if administered, must be tonic, never depressive. Suggestion also plays its part, but it, too must be tonic, not depressive.

That is, it must not be administered in the hypnotic trance, but directed to the waking consciousness, in order that the patient may accept it and respond to it by the exertion of his own will, not through coercion by the will of another. This is the danger line. Let the psychotherapist (Emanuel Movement) beware that he does not cross it.

All phases of abnormal psychism are fully covered in Volume IV of this series, entitled *Natural Eugenics*.

SECTION XXXI

MENTAL AND SPIRITUAL HEALING

1. Telepathy, the Language of Impulse
Telepathy means the transmission of words and ideas from mind to mind through vibrations in the ether. That this is possible is now a matter of common experience among those who are physically and mentally sufficiently refined to become sensitive to such etheric vibrations. A few years ago materialistic science would have dismissed telepathy as "another evidence of hysterical self delusion or as tricks of pretenders and fakirs".

This is hardly possible now in the days of wireless telegraph and telephone. If it is possible for metal instruments to transmit messages through thousands of miles of open wireless space, why should it be impossible to send mental vibrations from mind to mind and brain to brain through the all-pervading ether?

What is now possible to a comparatively few physically and mentally refined and sensitive individuals will in the course of evolutionary development become the common capacity of all mankind. Those who have attained the power to travel in foreign lands—that is, in the spiritual planes of life—assure us that in the higher spiritual spheres telepathic communication, the language of impulse, becomes the common mode of expression. Though we may not be aware of it, it is a fact that all of us are more or less sensitive while waking and possibly more so while sleeping, to thought vibrations and emotional vibrations from our physical and spiritual surroundings.

Every human brain and the consciousness back of it is a wireless telegraph with its sending and receiving apparatus. We live in a great sea of mental, emotional, spiritual and physical vibrations. Most of us are constantly sending forth our own vibrations and receiving those of other minds. Much of that which appears to us as our own thinking and feeling is thus inspired or forced upon us from without. This becomes particularly apparent in what has been called mob psychology. Our mental and psychical wireless connects us with all the planes and spheres of earth and heaven, of hell and purgatory, and with their inhabitants. The nature of the vibrations that we receive, whether they be cheerful or of a depressing nature, helpful or harmful, constructive or destructive, depends upon the quality of our own vibrations.

In order to make communication between wireless instruments a possibility, the sending and receiving apparatus must be attuned to the same range of vibration. So also the human wireless receives and registers those vibrations only which are nearest in vibratory quality to its own.

Thus the brain habitually attuned to the vibrations of hopelessness, fear, despair and melancholy will receive and register like vibrations from the earth plane and the lower and lowest spiritual spheres which are the abodes of gloom, remorse and despair.

In like manner, vibrations of greed, jealousy, revenge and cruelty will attract and register like vibrations from other depraved and cruel minds. From this it appears that those who
indulge in destructive mentalism and emotionalism intensify their own unhappy or depraved conditions through the operation of the law of spiritual attraction and repulsion.

I use the word "indulge" advisedly because destructive mental and emotional habits are just as much forms of self indulgence as are the drug or liquor habits. The person who indulges in fear and worry thought is just as much a victim of intemperance as the drunkard and drug fiend.

Lack of self-control is the cause of all vices; the exercise of self control the only remedy. The preacher of temperance may be surprised to learn that his fear and worry mania or his irritability and nervousness is just as much a matter of lack of self control and of intemperance as the liquor or cigarette habit of those whom he tries to reform by force of law.

The trouble is that people have not been taught that they can and must control their thinking and feeling just as strictly as their eating and drinking. They grow up under the impression that they cannot help what they think or feel—that thoughts and feelings come and go "as the wind listeth"; they think of the brain and mind as an Aeolian harp which is played upon by the passing breezes. They do not realize that the brain is a musical instrument under the absolute control of the will of the ego, that the will is the artist who may elicit harmony or discord from his instrument as he desires.

Fortunately the laws of spiritual attraction and repulsion work just as accurately in the constructive as in the destructive way. Just as surely as we can connect our mental, spiritual and psychical wireless with the astral planes and the deepest hells, just so surely can we connect them with the higher spiritual and celestial spheres and their inhabitants, with the invisible helpers and angels and with the all-pervading spirit of the universe whom we call God, the Father, the Logos, the Great Spirit, Brah, and by innumerable other names.

Just as surely as wireless connection with the lower spheres will fill our souls with the discords of unhappiness, remorse and despair, just so surely will connection with the higher spheres bring us an influx of more life, love and happiness, of "peace that passeth all understanding".

To illustrate the foregoing, think of a hall in which an orchestra is performing a great symphony. The audience, instead of listening quietly and attentively, creates loud and disturbing noises. Naturally the beautiful music is drowned in the general clatter and merely serves to increase the nerve racking noise. In similar manner the influx of peace, harmony and healing power from the higher spheres of spiritual and celestial life cannot fill the soul, cannot have a harmonious effect upon the physical, mental and psychical conditions of a person if mind and soul be agitated by discordant and destructive mental and emotional vibrations.

2. The Secret of Spiritual Healing
Mind and soul must be in a condition of perfect serenity and peace before they can receive the wireless vibrations of healing power from the source of all life. This is the modus operandi of true spiritual healing. It means the opening of our souls to the influx of almighty love from the source of all life and love in the universe.

Life and love are identical in nature. Love is the highest vibratory activity of the human soul as well as of the universe.

Why should we depend upon spiritual healers when within ourselves we have the shortest wireless connection between the human soul and the oversoul? A spiritual teacher cannot help us more effectively than by showing us how to establish this wireless connection and how to operate it.

A sufferer, confined to bed for many years, said: "You ask me to make myself receptive to the healing currents coming from the innermost source of life and power within me; you say I must relax and fix my attention and desire on the spiritual and celestial ranges of vibratory activity.

"I fail to understand how I can come into living contact with heavenly vibrations while confined in this hell of ignorance, sin and suffering." Smilingly, she added:

"Don't you think it a far call from Chicago to Heaven?" To this I replied: "It is within your power to receive as you desire—the discords of hell or the peace and harmony of heaven. Though the planes of mundane, spiritual and celestial life differ greatly in locality, the vibrations of the higher and highest spheres penetrate to the lower and lowest. Even the denizens of hell may catch glimpses of heaven.

"You fail to understand how it is possible for you to be in heaven and hell at the same time, yet, in this great city all spheres are represented in the souls of its inhabitants—the highest spiritual and celestial spheres as well as the lowest abodes of hell. It is possible for you to be at the same time in closest touch with these Varying places and conditions.

"Suppose your sick bed was surrounded with telephones, phonographs and kinetoscopes which transmitted to your eyes and ears the sights and sounds of these varying localities and conditions. What impressions you received would depend upon your desire, the direction of your attention and upon the refinement and receptivity of your physical and spiritual sensory organs. So your psychical wireless connects you with all the spheres of our planetary universe."

The invalid to whom I allude—a woman of about thirty-five years of age—had been confined to her bed for four and a half years, unable to turn from side to side, her physical body being slowly eaten away by cancer—the result of five surgical operations.

When I first called to attend her she had been suffering with the dread malady for two years Christian Science had been of no avail to ease her suffering. Morphine and other opiates
brought only temporary relief. From the day I first met her until the day she died, she never took another dose of painkillers or hypnotics. The simple, natural methods of treatment and her own serene and exalted mental and spiritual attitude made her suffering bearable and enabled her, under the most distressing circumstances, to remain in a cheerful and even happy frame of mind.

Her relatives and friends frequently assured me that instead of their having to console and cheer the sufferer, she was the sunshine of the home. As she became acquainted with the laws of constructive psychism and learned to control the higher and finer forces of mind and soul, it seemed that the spiritual predominated over the physical. Towards the end her consciousness was as active on the spiritual plane of life as on the physical. While her poor body was racked with pains, her spiritual eyes delighted in rapturous spiritual visions. It was undoubtedly the supremacy of the spiritual life over the physical which helped to keep her alive and which harmonized the physical vibrations sufficiently to ease her suffering and make it bearable. She had learned to connect her mental and psychic wireless with the highest vibratory ranges of spiritual and celestial activity.

This experience more than any other disclosed to me the marvelous possibilities of constructive mentalism and psychism as a healing power.
PART IV

BABY BOOK

Natural Therapeutics has undoubtedly solved the problem of treating human ailments. All other schools and systems will in time have to adopt the natural way. It is the hub of the healing art; all therapeutic methods radiate from it like spokes from a wheel.

Natural Therapeutics, however, has something better to give than treatment of disease, and that is prevention of disease. If children were brought into this world in the manner ordained by Nature and reared in harmony with the teachings of natural philosophy, disease would soon be a thing of the past. Human beings would then enjoy good health and be as beautiful and perfect in their kind as are animals, which live in the freedom of Nature, guided by instinct and therefore in harmony with the laws of their being.

We must begin, then, with prevention, for prevention is always easier and cheaper, than cure. But where must we begin to study the prevention of disease? Some will say, "At birth, because that is the beginning of life." Not so: that would be too late. The mould is made and the foundation laid for health or disease, for happiness or suffering, for efficiency or deficiency, before the human being in process of creation sees the light of day.

"Then," it may be said, "we must begin with prenatal influence, for the physical, mental, emotional and moral habits of the mother influence powerfully the development of the new life she is carrying." True—but we must start earlier than that. The making of the human being begins with mating and conception. All subsequent development depends upon the right start.

SECTION XXXII

Heredity

1. Importance of Correct Mating. Of primary importance in the sacred rite of procreation, as already intimated, is mating. This should take place only between descendants of the same subrace, or of closely related subraces such as the Indo-Caucasian and Celtic.

If the racial descent of the marriage partners is so far removed that it has produced pronounced differences in racial
characteristic—as in the case of the swarthy Mexican and white skinned Englishwoman, or the dark eyed Magyar and blue-eyed Scandinavian—then procreation becomes miscegenation and degenerates into mongrelization of the offspring. Everywhere in the animal and human kingdoms Nature has set the mark of disapproval on the mongrel. The offspring of miscegenation is doomed to deterioration and extinction unless assimilation of the elements of a lower race by a higher takes place sparingly and gradually.

The law of racial purity may be summed up as follows: When a member of a higher race cohabits with a descendant of a lower race, the offspring of the union loses more or less the characteristics of the higher race and reverts in physical, mental and moral traits to the level of the lower race.

The constructive results of racial purity are evident in Hindus of the higher castes; in that portion of the Jewish race which in mating has faithfully adhered to the Law of Moses, and in the blond and blue-eyed remnants of the Indo-Caucasian and Celtic races in Northern Europe and North America. The destructive results of miscegenation are plainly evident in the mongrelized population of Mexico and everywhere in the half-breed and many kinds of mixed breeds. These usually fall below the physical, mental and moral standards of the parent stock, and almost invariably revert to the customs and habits of the inferior race.

2. **Use Heredity.** Use heredity deals with the transmission to offspring of *acquired* physical, mental and moral characteristics of the parents. According to this law as it has been formulated, the chances of the offspring for long life, health, mental efficiency and moral stamina, other conditions being favorable, are better in direct ratio to the advancing age of the parents at the time of conception. While this is contrary to popular opinion, which assumes that younger parents produce more perfect offspring than older ones, the fact of use heredity is proved, both in the animal and human kingdom, by common observation and statistical evidence.

The working of the law is based on the fact that the procreative elements of the parents, or rather the microzyma of those elements, cannot contain the impress of physical, mental and psychical characteristics which at the time of procreation were not developed in the threefold organisms of father and mother.

The age of the father at conception is called the "birth age" of the offspring and determines its birth rank. While the father and previous male ancestors, for reasons hereafter explained, seem to exert greater control over the mental and physical characteristics, the mother furnishes the nutrient soil for physical growth. This does not mean that she exerts no control over the mental and psychical characteristics of the offspring; in addition to her influence through use heredity she has added opportunities through prenatal influence and postnatal training.
According to this law, then, the chances of the offspring for excellent physical, mental and moral development become better as the age of the father at the time of procreation advances beyond thirty five; while the physical condition of the mother for reproductive function is best below thirty five years.

But we must not overlook the fact that too great a discrepancy of age between the man and woman may become the cause of physical and mental incompatibility, of aversion and great unhappiness, especially on the part of the younger woman.

Extensive statistical evidence seems to prove that the birth age of the mother has been of less importance than that of the father. As will be shown in Natural Eugenics, the majority of famous men in all lines or human endeavor had old male ancestors, while the mothers and previous female ancestors were of much younger age at the time of conception.

This may be accounted for by the following reasons:

The man is usually considerably older than the woman at the time of marriage. Men, as a rule, devote much more time and effort to acquiring a scientific, professional or business education than do women. This has been true in the past more than it will be in the future. Thrown early into the competitive struggle of life men generally have had to make greater mental and physical effort than have women.

These points are of considerable importance because it has been proved that it is not inherited brain mass and mental capacity, but strenuous and persistent effort that intensifies use heredity. The earlier this begins and the longer it continues before procreation takes place, the better the chances of the offspring for physical, mental and moral capacity.

The reproductivity of the mother has usually ceased at thirty-five. Though she be capable of childbearing a few years longer, usually conception has been avoided after that age. Men under favorable conditions remain reproductive to advanced age. Some of the world's greatest men descended from fathers over sixty years old.

That intellectual and creative capacity has followed the male line of descent rather than the female line, is indicated by the fact that the high intellectual capacity of many eminent men has skipped their daughters to reappear in male descendants. This may be partly accounted for by the fact that the daughters in their limited spheres of activity have not had the opportunity to unfold inherent intellectual capacity to any conspicuous degree.

There has been a tendency in some quarters to criticize the general entrance of women into professional and commercial life and to dilate upon the adverse influence this will have
upon womanly characteristics and family life.

In the light of the knowledge we possess upon the subject of use heredity, it is safe to say that any such problematical drawbacks will be far outweighed by the general postponement of the marriage age. This will insure not only better physical fitness but also higher intellectual development and greater moral stamina on both sides of parentage.

The tremendous benefits which this increased hereditary endowment will confer upon future generations cannot be overestimated. Greater intellectual and economic equality between the sexes will emancipate woman from degrading sexual subservience. Under the old order, sex appeal was too often her only stock in trade by which to attract and hold the male and thus to secure a living. Economic independence will insure greater consideration and higher esteem for the woman on the part of the man. It will go a long ways toward solving the problem of birth control in a natural way, by leaving it more largely to the judgment of the mother.

We find the law of use heredity according to birth age verified in the intelligence and moral development or obliquity of races, nations and tribes all over the earth—The lower the average birth age of a race or nation, the lower, other things being equal, the intellectual and moral development The greatest development and efficiency is found among those nations where marriage is delayed to a later age through custom, economic necessity, professional or military training.

The following quotation from "Control of Heredity", by Casper Lavater Redfield, is of interest in this connection:

"In general it may be said that wherever there are no restraints upon the sexual propensities, as with the Digger Indians, the Fuegians, the Andamanese, the Wauraus of the Guianas, the Bushmen and the tribes along the Gabbon river, there we find reproduction taking place at the earliest possible age, and the lowest grade of intelligence. Where we find some special circumstances or customs that delay the age at which reproduction takes place, as with the Patagonians, the North American Indian and the Polynesians, there we find considerably higher grade of intelligence.

"Where we find the custom of marrying late in life, as was customary with the Greeks and the Romans, there we find a very high grade of intelligence. And where we find a fortuitous succession of very late births, there we find the very great men of the world's history.

"In other words, the longer the time in which the individuals have in which to use, develop and strengthen their brains before reproduction begins, the greater and more powerful are the brains of their descendants."

In Volume IV of this Series I shall quote elaborate and
highly interesting statistics from Redfield, which reveal the effects of the various birth ages on physical, mental and moral characteristics. I shall confine myself, for the present, to the statement that, with few exceptions, the great artists, scientists, philosophers, statesmen and philanthropists were born from fathers whose ages ranged from forty to sixty-five years at the time of the procreation of their famous offspring.

The existence of these laws and principles as facts in nature is very evident in the training of racehorses and of other animals along certain lines of proficiency.

3. Pernicious Heredity. The effects of deteriorating and destructive heredity prenatal and congenital influences have been traced and commented upon in so many different ways that I do not believe it necessary to enter deeply into this phase of the subject. Various authors have filled entire volumes with the unsavory family histories of the descendants of the Jutes, Ishmaels and other drunkards, prostitutes, degenerates and criminals, which prove positively the transmission of morbid and pernicious traits through successive generations. It has been proved statistically beyond the shadow of a doubt that youthful delinquency, pauperism and criminality are the aftermath of immature marriages.

The laws of use heredity and prenatal influence, like all other natural laws and principles, manifest along opposite lines of expression. It remains for us to determine whether we shall align ourselves with their destructive or constructive activities. The effects upon ourselves and our offspring will show accordingly.

If I succeed in arousing the consciousness of prospective fathers and mothers to the glorious privileges and enormous responsibilities which these laws of nature confer upon them, then my labor will not have been in vain and I shall feel deeply gratified.

SECTION XXXIII

1. The Creative Alchemy of Love and Affection

Procreation—as is the case with everything else pertaining to the constituents and functions of the human entity—takes place on three planes of being, the material (physical and spiritual), the mental and the psychical planes. Which of these elements shall predominate in the offspring depends upon the mixture and adjustment of qualities in the triune makeup of the mating couple. In order to fulfill the law and to draw the divine blessing upon themselves and the fruit of their union the partners in the procreative function must be united by the bonds of love, or at least by the ties of true affection.
The source of creative genius is love and wisdom, and the essence of intelligence and power is sincerity and goodness. Without these, intelligence degenerates into selfish cunning, power into self-destructive brute force. The spring cannot rise higher than its source; its water cannot be pure and wholesome when contaminated by impure admixtures from filthy surroundings.

It is not generally known that use heredity pertains to intellectual and psychical qualities, as well as to the physical material. Animalism breeds nothing but selfish animalism. The vampire who craves and absorbs the love of its victims and robs them of vital energy, without being capable of feeling or bestowing affection, is the child of a discordant union—of brute animalism on the part of the man, of secret aversion and hatred, usually, on the part of the woman. These bestial and degrading tendencies on the one side, and unrequited love craving on the other, breed sex perversion, and propagate the harpies who delight in the seductive power of superficial beauty, while gloating over the weakness and ruin of their victims.

True love and affection, paired with intelligence and goodness; liberate the creative elements necessary to the production of perfect offspring.

The finer qualities of mind and soul open the fountains of life on the higher planes, liberate and harmonize the male and female procreative fluids, and charge them with the purest and most potent intellectual, spiritual and psychical elements.

The divine fire of creative genius burns only in the love aura of truly mated couples. It is true that these are rare under our artificial, unrighteous social institutions, and that accounts for the rarity of complete manhood and womanhood.

Perfect offspring, endowed with beauty and power of body, mind and soul, destined to shed through life a radiance of health, happiness and helpfulness—to love and be loved—issues only from the union of love and affection with intelligence and goodness.

"Love lieth at the foundation" (of all that is). "Love is passion, enthusiasm, affection, heat, fire, soul—God."

To the extent that love enters into the holy rite, to that extent its attributes will be absorbed in the threefold organism of the woman and become active in the child building in her womb. While she loves her man more than ever, her most passionate affection is centered in the new being in process of development. On it she bestows the purest and best in her food and drink, in her thoughts, emotions and secret desires. Fear, worry, anxiety, jealousy and hatred are strangers to her soul; these are the emanations of the lower spheres—she lives in heaven.

Somebody endowed with deep insight into these matters has
said:

"Whatever male and female shall truly will for, hopefully pray for and earnestly yearn for, when love pure and holy is the nuptive ascendant, in form, Passional, affectional, divine and volitional, that prayer shall be granted, and the boon be given—but the prayer must precede."

What are the direct effects of the marital rite upon the participants? If the sex attraction operates on the physical material plane only, if lust instead of love presides at the matrimonial feast, then temporary gratification of erotic craving will be followed inevitably by monotony, satiety, gradual revulsion and aversion, culminating in a morbid craving for change and variety. The partners in carnal self-indulgence are intuitively aware of these tendencies to marital unfaithfulness, and, therefore, easily dominated by distrust and jealousy.

The procreative function is attended by complete satisfaction, buoyancy of body and mind and lasting happiness only when sex attraction operates on the higher and highest planes of being, as well as on the lower, when desire and impulse are operative on both sides. Thus only will the generative function fulfill its sacred purpose and confer the highest possible benefits upon parents and offspring.

The woman, being the more highly sensitized, must be responsive to the call of holy passion. To force unwilling compliance will ruin the woman, kill her love and curse her offspring. Balzac says: "He who begins with his wife by a rape is a lost man." It is impossible for a wife to love unless she is won, not forced to compliance.

**2. Sexual Intercourse During Pregnancy.** Sexual intercourse should be considered the most sacred function of the human entity. From the highest and best viewpoint it should be exercised only for the propagation of offspring. However, considering the present stage of ethical and moral development, temperate indulgence may not be wholly condemned. Excessive intercourse is always weakening and harmful to both participants. We must remember that the sex fluid is the carrier of the life force. It is that which constitutes strength, resistance to disease, initiative and genius. **During abstinence from intercourse the sex fluids with their creative energy are absorbed through the inguinal glands into the organism and increase physical, mental, moral and spiritual capacity and energy.**

Set rules for frequency of intercourse cannot be given. This must depend entirely upon individual conditions. One safe rule is that after indulgence there should be no feeling of satiety, weakness and exhaustion. The more frequent the indulgence the stronger will grow the power of habit and of passion and the greater will become the abnormal craving. It is the same with all other appetite and passions. The more frequently they are indulged, the stronger they grow, until
they attain complete control and develop into destructive habit

A free and confidential understanding in regard to these matters between those who contemplate matrimony would go far to prevent marital misery. A great deal of unhappiness arises from the fact that mates in the matrimonial union often labor under misapprehensions concerning the attitude of each toward the sex relation, and are prevented by excessive sensitiveness and delicacy from frankly discussing it. (For further discussion of this subject, see page 390, Volume I.)

There is no problem of married life that needs more thorough mutual consideration and understanding than this one. Lack of it accounts for a great deal of "incompatibility," loss of love, revulsion, hatred, and the final tragedy in the divorce court.

Among animals, no female allows intercourse after conception. In this respect as in many others, man has sunk below the natural standards of the animals. No greater crime can be committed against the woman and the unborn life.

It is a sad commentary on our system of education, scholastic as well as religious, that our young people are not instructed before and after marriage in these all important laws of Nature. To do this should be the province of the priest who unites them in marriage, or of the family physician, if the parents have failed in their duty.

It is well known (notwithstanding the denials of medical skeptics) that the unborn infant may be "marked" by transitory impressions, especially by strong emotions; that even insignificant parental characteristics are reproduced in the offspring. Is it any wonder, then, that the most powerful of human emotions should leave its impress on the growing brain and sex centers of the fetus, causing abnormal and precocious sex consciousness?

All too often is sex perversion born and bred in bone and flesh, before the child sees the light of day. The mother cannot be blamed for this "slaughter of the innocents"; she has not been instructed on the subject. Though she intuitively senses the horror of it, she submits, in order to maintain her hold upon the man—and many a life is thus cursed before it is born. The fault lies primarily with those of the medical profession who teach our young men that the free indulgence of sexual passion is not only legitimate, but a necessity to manly vigor.

This dictum of pseudo-science is almost universally concurred in by spiritual guardians. No greater lie was ever promulgated from the blackest abyss of Hades. If our young men were taught that greater happiness is to be attained by the exchange of tender affection than by the indulgence of the coarser animal appetites, that the creative forces thus preserved develop and strengthen their own finest capacities.
of body, mind or soul, they would wisely and chivalrously protect mother and child, at the same time conserving their own physical and moral integrity.

In no other way is it possible to call forth the deepest gratitude and unfailing esteem of a true woman. Many a man whom we have thus advised has become a lifelong friend in consequence.

3. Limitation of Offspring. I believe that the unlimited production of offspring, encouraged in some quarters for swelling the ranks of religious bodies or for increasing tax paying and cannon-fodder material, is a misfortune, both to the family and to society. Limitation of offspring, in accordance with the means and circumstances of the parents, is not only justified but should be encouraged. In any case, the production of offspring entails great responsibility upon the parents and if they cannot properly comply with the needs and rights of their children, they fail in their responsibility and duty.

Any method, however, which interrupts intercourse or prevents conception in an artificial way, is absolutely to be condemned, because this has very harmful and positively destructive effects upon the physical, nervous and mental organism of those who thus try to cheat nature by the suppression of a natural process. In our professional work we frequently meet the victims of such pernicious practices. The ordinary contrivances for prevention make of intercourse something akin to masturbation. This is also true of intercourse without orgasm which is strongly advocated under various guises. The use of poisonous antiseptics and germ killers in warm water douches is not essential for prevention, and is highly injurious. These chemicals have a tendency to poison the sexual organs and to produce in time atrophy, many kinds of female disorders, and tumors. Undoubtedly the greater number of so called female troubles and malignant tumors in later life are caused by curetments, antiseptic douches and the use of poisonous drugs, for producing abortion. The only legitimate methods of birth control are abstinence or common cleanliness.

There is nothing more conducive to the physical, mental and spiritual health and development of a woman than childbearing and child rearing in harmony with Nature's laws, as outlined in these volumes. Under favorable conditions it is not a thing to be dreaded, but to be looked upon as the greatest of blessings and opportunities in the life of a woman. Natural philosophy and practice takes these problems of procreation, childbearing and childrearing out of the domain of uncertainty and haphazard management with its dire consequences, and makes eugenics the most exact of all sciences and the sublimest and most enjoyable of all the arts.

4. Determination of Sex. Numerous theories have been advanced concerning this interesting subject. Many attempts have been made to wrest from Nature the secret of sex
determination and numerous more or less ingenious methods have been recommended for sex control.

I know of one method only which seems to have a rational basis and which has proved of practical value. Observations seem to prove that the right ovary liberates male ova only, while the left ovary discharges female ova. The two ovaries discharge ova only at alternate menstruations.

With this data at hand, it is possible to determine the sex of a child after one birth has taken place. Suppose the first child was a boy. By consulting our pregnancy table (page 377) we can determine when the last menstrual discharge took place. This menstruation liberated a male ovum; the next menstruation would liberate a female ovum, the next a male, etc.

Thus, using the last menstruation period before the last conception as a fixed point, it would be possible, figuring from period to period, to determine the sex nature of the ovum to be discharged at each following menstrual period. Account is taken of all regular periods during the time menstruation is suspended in pregnancy. Thus, conception may be timed in such a way as to impregnate at will a male or female ovum.

This solves in a simple, rational manner another of Nature's riddles, namely, the reason for the practically equal division of the sexes.

SECTION XXXIV

Prenatal Influence

There exists just as much diversity of opinion among scientists concerning the reality of prenatal influence as about race heredity, use heredity, disease heredity and many other mooted problems of science and philosophy, which we shall study in Vol. IV of this series. In the following I shall present and examine impartially the various theories and opinions concerning prenatal influence; then we shall be better prepared to draw our own conclusions.

1. Medical Science Denies Prenatal Influence. Medical men, as usual cocksure of the correctness of their theories and hypotheses based on the "latest discoveries", deny and ridicule the possibility of prenatal influence, and relegate it to the rubbish heap of popular superstitions. They base their judgment on the fact that no nerves pass from the body of the mother through the umbilical cord into the growing fetus in the placenta, which forms the soft protecting nest of the new life within the womb. They claim that since no direct nerve connection exists between the two, mental and emotional vibrations cannot be transmitted from the brain of the mother to the brain and nervous organism of the fetus.
Are there no other means of communication between the mind of the mother and the brain of the unborn!

In the volume dealing with Eugenics we shall learn how universal intelligence and creative will become individual intelligence and personal will.

Cosmic vibrations do not flow into the gray matter of the human brain over coarse physical nerve tracts. They come over the psychical wireless which connects the human soul with the world Soul, the individual intelligence with the universal or cosmic intelligence the human will with the divine will.

Since, as proved by modern brain and nerve anatomy, immaterial cosmic intelligence and "power to will" fashion the brain of the mother into physical material centers for the expression of human intellectual faculties, capacities and powers, why cannot these cosmic vibrations act in like manner over the psychic wireless through the soul and mind of the mother on the brain and nervous system of the fetal organism?*

These epoch making discoveries and revelations of modern brain anatomy are explained in Vol. IV of this Series, *Natural Eugenics—Man Building on the Physical, Mental and Moral Planes.*

Why should the wireless, which transmits impulses of intuitive intelligence from the great source of all intelligence and creative energy into the soul of the mother, cease to operate at that point, and fail to transmit its message to the brain and nervous system of the fetus which is most intimately related and connected with the organism of the mother?

What about the phenomena of hypnotism? Absolute control of the subject's mind, through the intelligence and will of the hypnotist does not depend upon the existence of an umbilical cord and physical nerve connection between the two. The hypnotist, by silent command, may call his subject from a distance, far beyond the reach of his voice.

People telepathically attuned may communicate in like manner, spontaneously, or by conscious intent. Why then should we doubt the possibility of vibratory correspondence between the mental and emotional conditions of the mother and the plastic nervous organism in process of development within her womb?

If a complexity of sound can impress itself permanently upon the wax cylinder of a phonograph, or what is still more marvelous, if the photographic rays of passing scenes can be fixed and retained in the picture film, why should it be impossible for the mental and emotional vibrations of the mother to impress and modulate the molecular and cellular constituents of the fetal brain and nervous organism?
I have compared this creative power of the mother mind to the process of electrotyping. As the particles of metal in suspension in the fluid adhere to the spoon that is to be coated with silver, so the atoms and molecules in the gray matter of the brain of the fetus group themselves in harmony with the thought forms and emotional vibrations of the mind and soul of the mother. While this mental and psychical electrotyping takes place automatically, the mother's brain and nerve molding power can be greatly strengthened and intensified by the conscious and voluntary operation of the psychical wireless that establishes vibratory oneness between her and the human entity in process of development within her own body.

Thus it is revealed how a brain prenatally refined, organized and fashioned may endow the nascent individuality with certain aptitudes and talents along established paths of cerebration. There surely will be less resistance along such lines of physical, mental and moral endeavor than along other lines not prenatally influenced and molded. Therefore I strongly advise mothers, pregnant with new life holding marvelous possibilities for good or evil, not to be influenced by the superficial reasoning of materialistic science, but to follow the sacred intuition and impulse of their own creative genius in this, the most holy function of their being. Every normally constituted mother is intuitively aware of this wonderful power, and is willing and anxious to exercise it when her consciousness has been aroused to the great possibilities and responsibilities which the divine privilege of motherhood confers upon her.

It is natural for us to admire a great artist who portrays the human form, true to life, on the painted canvas, or who fashions it from inanimate stone, metal or marble; how much more grand and godlike is the creative power of truly mated parents whose privilege it is to bring into the world, and to fashion according to their highest ideals, a human being endowed with life and intelligence, with the infinite possibilities of a new center of creative activity.

Yet many mothers, totally ignorant of their divine creative privileges and possibilities, victims of physically and morally degrading marriage relations, and often filled with secret aversion or open hatred for their marital companions, pass unwillingly through pregnancy and not infrequently seek to destroy the new life. When the unfortunate victim of such marital incompatibility, conceived in passion and developing under the worst possible influences of mental and emotional discord, comes to arouse the maternal instincts of affection and devotion, then fear, anxiety and worry, like a continual nightmare, haunt the unhappy mind of the mother and impress their discordant vibrations upon the sensitive films of infant consciousness.

Compare this condition of fear, apprehension and gloom in the mind and soul of an unhappy and unwilling mother, with the joyful and ecstatic state of mind of a mother conscious of
the creative power of her intelligent will, who, from the time of mating and procreation, with accurate prescience prepares the most favorable conditions, astrologically, prenatally and postnatally for the finest development of the physical, mental and moral characteristics of the future world citizen.

The loftiest exaltation of a creative genius working in dead clay and cold marble cannot approach the ecstasy of a mother who has acquired a knowledge of the great laws which make possible the development of a perfect human being,—the embryo of a master, an angel, a being destined to be godlike in its faculties, capacities and powers!

In place of fear and anguish of soul, what joy to the mother who knows that it lies within her power to prevent disease and degeneracy in her offspring; that the development of the child depends solely upon her own intelligent effort! Nothing is left to accident. Child bearing becomes an exact science, the most beautiful and inspiring of all arts and professions. Under such conditions motherhood, instead of being the greatest of hazards and hardships, becomes a divine privilege and the highest achievement of human existence and endeavor. It falls short only of the creative work of the great Universal Intelligence whose instrument of creation is the mother.

2. An Example from History. Let us consider the oft-quoted example of Napoleon Bonaparte. His mother, Lutitia Bonaparte, while pregnant with the future military genius, accompanied her husband on a military expedition, sharing with him the hardships and excitement of camp life, and the marches and battles of a military campaign. If there be nothing in prenatal influence, is it not singular that Napoleon should have become one of the greatest military geniuses of all ages, while not one of his many brothers ever exhibited enough military ability to make an efficient corporal? What was it that favored or determined the birth of the great military prodigy under these circumstances? The ancestors of Napoleon's father were not professional soldiers, nor was the father especially interested in military matters before the conception of his gifted offspring.

The dominant influences, therefore, must have operated through the singular occupation and surroundings of the mother during this particular pregnancy.

Many similar striking examples have been cited in works on prenatal influence. I myself might add many convincing proofs from an extensive experience in medical practice; but time and space do not permit. Contributory evidence may be secured from many excellent works dealing with this vital problem in human life. I may be permitted to say that use heredity and prenatal influence are distinctly manifest in the physical and mental characteristics of our three children who were born at intervals of seven and five years. Each one of them clearly mirrors in his or her physical, mental and emotional peculiarities the predominant mental tendencies, occupation and surroundings of the parents during the
respective prenatal periods. Similar manifestations of prenatal influence may be observed in almost any family.

3. Birthmarks. Medical men of late deny also the possibility of "marking" the offspring by sudden fear or shock on the part of the mother during pregnancy. Incidents of this kind, however, are of such common occurrence that it is a waste of time to refute these flippant denials.

There are good reasons for believing that such marking is more likely to occur during the periods when the menstrual flow should take place, but is suspended.

It may be argued that to mention the possibility of marking to a pregnant woman will greatly increase the probability of electrotyping violent emotions upon her offspring; in other words, that the fear of the thing will help to materialize it. This may be true to a certain extent, but we must remember that sudden shock through fear or disgust may cause the mischief anyway, whether or not the expectant mother is aware of the possibility. Understanding a danger and being prepared for it seems the best protection. The pregnant woman should study carefully section XXX, dealing with mental and emotional causes of nervous diseases, and should learn to relax to any sudden surprise and thus neutralize unpleasant and fear arousing impressions. Self-control is the royal remedy and the key to mastery.

4. Physical Influence. Now that we have studied some of the more important hereditary mental and psychical prenatal and postnatal influences, let us see how the physical condition of the mother's organism influences the brain and nerve matter of the fetus in its last stages of development, and after birth.

Materialistic science teaches that brain matter exudes thoughts and feelings, as the liver excretes bile, or the stomach pepsin. Natural science proves that mind is superior to matter, that the new born ego, by the power of intelligent volition, must fashion in the gray matter of the brain the molecular groupings or centers for the expression of intellectual and emotional activities, such as language, music, numbers, scientific and philosophic speculation.

This means that active cerebration and brain molding do not begin until after birth. But it stands to reason that the work of the nascent intelligence may be greatly facilitated or impeded by the physical condition of the brain. It is reasonable to assume that intellectual and emotional vibrations will more easily shape the gray matter of the brain into new configurations when it has been prenatally refined, organized and developed along certain lines of cerebration by use heredity and by constructive prenatal influences.

There exists a remarkable similarity between the brain molding and memory building activities of the intelligent ego and the making of phonographic records and moving picture
films. Lifelike impressions of sounds and passing scenes can be made upon the phonographic and photographic mediums only when wax and film are in a highly refined and plastic condition. When impure of substance and coarse of texture they, are not sensitive and plastic enough to register and retain the subtle and highly complex vibrations of sounds and passing scenes. In order to receive and register a great variety and complexity of sounds, the wax on the phonograph cylinder must possess a certain degree of refinement, softness and plasticity. If it is too hard and coarse it registers the loud and coarse sounds only. Such a record cylinder, exposed to a beautiful symphony executed by a great orchestra, would register and reproduce only the shrill cries of the trumpet, the rattle of the snare drum and the booming of the big horns and bass drums. The softer sounds of string, wood and wind instruments and finer shadings of tone and rhythm would be lost. With increasing refinement and plasticity, more subtle and delicate sound vibrations will be retained and reproduced.

In like manner the sensitive gray matter of the cortex of the brain must be in a pure and plastic condition in order to receive and register the impressions and impulses coming through the sensory organs, the psychic intuition and the intellectual and emotional activities of the mind. Anything in the way of physical impurity or foreign matter that tends to clog the brain, or to feed it with waste and morbid materials, or with corroding poisons, will lessen the atomic and molecular motility of brain and nerve matter, and will interfere with, or impede, the groupings and subtle transformations involved in the fashioning of brain centers through mental and emotional influences.

If the nutrient blood which feeds the brain substance of the fetus be saturated with CO$_2$, the benumbing, paralyzing carbon-dioxide, with clogging uric acid or the destructive acids of phosphorus and sulfur, the gray matter cannot, respond to the subtle and complex impressions and impulses from without and within.

The purity or impurity of the plastic matrix of the cortex depends upon the materials absorbed from food and drink. If these are so constituted as to create in the system excessive amounts of clogging and corroding substances, then these food and drink poisons will have a benumbing and deteriorating effect upon the sensitive gray matter of the brain, as well as upon the coarser tissues in the joints, muscles and vital organs. There is a rheumatism of the mind as well as of the joints.

A brain asphyxiated and clogged with pathogenic materials cannot be alert and active; it is too dull and lazy to think; it would much rather sleep than work; it is incapable of doing its best when its tiny blood and lymph vessels are obstructed with waste and morbid deposits which prevent the oxygenation and drainage of its delicately organized cellular tissues.
This, of course, is true postnatally as well as prenatally. A brain originally capable of the highest and finest achievements of the human mind may become utterly worthless, and may degenerate into idiocy through food, drink and drug poisoning.

Medical men tell mothers they need not worry over prenatal feeding, because the placenta, the vascular bag which forms the nest of the new life, acts as a filter which purifies the blood before it reaches the fetus. Common sense and every day experience tell another story. Even the best in the blood of many mothers is bad enough to serve as food for the new life.

The placenta does not filter out of the blood of the mother all food, disease and drug poisons. This is proved by the wretched condition of many infants, suffering from malnutrition, anemia and rachitis, after delivery. If the vital fluids of the mother are deficient in the mineral elements, or in other important nutritive substances, how can they deliver them to the fetus?

Occurrences like the following, quite common in our institutional practice, prove positively that the placenta is not a perfect filter for systemic poisons and for disease taints circulating in the blood of the mother.

One of the most pitiable cases of eczema in a little child less than one year old we traced to the fact that the mother, during her first year of marriage, had traveled with her husband through Eastern European and Asiatic countries, and during her pregnancy had been vaccinated five times while passing through localities where smallpox was prevalent. Both she and her husband had always enjoyed perfect health. The family record was excellent as far as traceable; still the body of the infant soon after birth, was covered with open bleeding sores, presenting a revolting sight. We could find no explanation for this strange phenomenon other than the many vaccinations during pregnancy. These had contaminated the blood of the mother, and through her the body of the fetus, with a filthy scrofulous taint.

The baby suffered terribly. For many months it slept but little, because of the excruciating pains. The eczematous eruptions were of a very stubborn nature; they broke forth again and again. Finally, however, after eighteen months of natural treatment, we succeeded in purifying the little body of the horrible infection. The child is now a little over three years old, in perfect health, and during the last twelve months has shown no signs of the morbid taint.

Under another section I shall describe the influence of food upon character and sex life.

To recapitulate: Purity, plasticity and motility of the highly refined and sensitive materials which make up the gray matter of the brain depend upon pure food, plenty of fresh air and exercise, and upon all other natural methods of living.
SECTION XXXV
Conception and Pregnancy

1. Conception takes place whenever the male spermatozoon joins the female ovum (egg) within the woman's womb. Normally the female organism liberates from its ovaries but one ovum each month, usually during menstruation, while the male discharges millions of spermatozoa at each orgasm.

Conception does not always follow copulation. The ovum remains in the womb and is capable of impregnation for about five days after menstruation. The spermatozoon on entering the womb may meet an ovum which has been discharged at a previous menstruation, or it may remain alive in the womb for a number of days and finally come in contact with a newly discharged ovum at the following menstruation.

The spermatozoon retains its ability to impregnate the ovum for from ten to fifteen days after its discharge into the womb. When the male and female germs merge into one another, conception or impregnation takes place. As soon as this has happened, the impregnated ovum becomes attached to the inner lining or mucous membrane of the womb and begins its new life as an embryo. The period comprising the time from the impregnation of the ovum until the beginning of labor or childbirth is called pregnancy.

The table of pregnancy on page 377 indicates the probable date of normal termination of a pregnancy, calculated from the last menstruation.

2. Exercise During Pregnancy. Unfortunately a great many expectant mothers labor under the idea that they must rest and be relieved from work and exercise. This of course is a great mistake. Light housework is good exercise. There is nothing more harmful during pregnancy than nursing "that tired feeling" by lounging idly about the house and coddling one's real or imaginary aches and troubles.

Of great benefit to the pregnant woman are all outdoor sports such as tennis, golf and other games which require vigorous exercise without straining or overworking the body. The great benefit of walking and other outdoor exercises, aside from their general invigorating effects, lies in the strengthening of the abdominal muscles and ligaments, which at delivery will greatly facilitate expulsion of the fetus.

The walk should be brisk and rhythmical, body erect, head thrown back, chest forward; the breathing at the same time should be deep and regular. These walks should be continued as long as time and endurance permit. Nothing, of course,
must be pushed to the point of exhaustion. One good long walk every day is necessary; two are better.

We all understand the necessity for a plentiful supply of oxygen under ordinary conditions, and especially in time of illness. During pregnancy the demand for oxygen, as well as for mineral salts, is doubled or trebled on account of the needs of the rapidly developing organism in the womb of the mother.

These extra demands for oxygen and ozone must be supplied by systematic deep breathing, cold bathing, outdoor walks, etc. If circumstances do not permit the taking of outdoor exercise, deep breathing should be practiced as often as feasible, at the open window.

Next in importance among gymnastic exercises is the internal massage described under section XXI, No.16.

Those exercises are especially valuable which bring into play the abdominal muscles and the muscles and ligaments of the genital organs.

3. Clothing. Clothing and the manner of wearing it profoundly influences the normal or abnormal development of the fetus, the health of the mother, labor and delivery.

At no time should the waistline be constricted by a corset or even by the ordinary skirt band. All clothing should be as loose and light as possible—one-piece under and outer garments, with the weight suspended from the shoulders, are best. If skirts are worn they should be fastened to skeleton waists of some thin cotton material. The close, heavy texture of the material from which the corset or so called "reform waist" is made is injurious because it interferes with skin elimination.

Even the slightest constriction of the waist line interferes with the free circulation and the normal blood supply to the abdominal organs, which is of especial importance in pregnancy; it also hinders the free expansion and movement of the uterus during the various stages of pregnancy.

Within the waistline are located a dozen or more important vital organs of the body. Any sort of constriction compresses these organs and pushes them out of their normal position. While this is extremely injurious to the body of a woman under ordinary conditions, it is doubly so to the pregnant mother and to the rapidly growing fetus. Undoubtedly many deformities and monstrosities are produced by unnatural constriction of the blood vessels and vital organs in the abdomen and pelvis of the pregnant woman.

If due attention is paid to the foregoing influences, labor and delivery will be brief and easy. This we have proved in hundreds of cases which have come under our management. The reason why women of civilized countries spend many
hours and sometimes days in dreadful agony of childbirth while those of primitive or savage races, as we call them, produce their young easily and painlessly as the animals do, is that primitive women live more simple and natural lives, while "civilized" mothers violate practically every law of Nature in their daily habits of living.

Civilization unfortunately stands in many respects for that which is artificial, unnatural and therefore productive of disease and suffering in all domains of life, not only as regards physical health, but social and political health as well.

SECTION XXXVI

Danger Signs During Pregnancy

1. Dropsical Swelling. Swelling of the limbs and distention of the veins of the legs during pregnancy may be caused by a tendency towards varicosity, intensified by obstruction of the circulation due to the enlarged uterus. Such a condition requires, aside from the natural regimen, careful and competent treatment.

Swelling of the limbs or other parts of the body may also be caused by incipient or advanced Bright's disease. The urine should be examined from time to time, especially if there is a swelling of the feet and ankles, or if there are dropsical symptoms in other parts of the body.

Such dangerous conditions are usually brought about through the excessive intake of starchy and protein foods which overwork the liver and kidneys and cause pathogenic dogging of the capillary circulation. This may result in uremia attended by violent and sometimes fatal Convulsions.

2. Uremia is the result of retention in the system of waste materials and poisons that should be eliminated through the kidneys and skin. Medical treatment for such conditions, aside from the administration of stimulating drags, consists in hot bathing with the idea of opening the pores of the skin.

We understand that all hot water treatment gives only temporary relief and is followed by greater enervation and inactivity of the skin. The best water treatment for systemic poisoning of any kind consists in the application of wet packs followed by cold ablutions as described in section XV.

The addition to the packs, dry friction rubs, air bath, good massage and neurotherapy treatment will aid in restoring the normal activity of skin, bowels and kidneys.

Whenever the urine contains sugar or albumen, fasting, alternating with raw food diet, is indicated. Suitable regimens are outlined in sections X, XI.
The giving of heavy food to the mother with the idea of increasing the flow of milk is all-wrong. We have found in all cases that the diet outlined in section X will produce a more copious flow of rich milk than the "nourishing" meat diet. The best remedy for a scanty flow of milk is slow and thorough mastication of a few spoonfuls of raw crushed wheat every day.

3. Morning Sickness. One of the common disorders experienced during pregnancy is known as Morning Sickness. One suffering from this ailment, though following a natural diet, should sip a cup of hot postum while remaining in bed. If this does not have the desired effect and if the patient has not been accustomed to drinking coffee, half a cup of black coffee with a few drops of lemon juice will quiet the irritated nerves. It is necessary after taking the hot drink to remain in bed for at least thirty minutes. It is understood that this is only an emergency measure. If continued, it will lose its good effect and work injury.

SECTION XXXVII

Labor and Delivery

At about forty weeks, exactly nine solar months, from the period of conception the fetus reaches full maturity, and labor begins. Labor is divided into three stages. During the first stage the neck of the womb becomes slowly and gradually distended and the orifice of the womb opens widely. When this has taken place, the fetal membranes burst and the amniotic liquid surrounding the fetus escapes.

During the second stage the fetus emerges from the womb.

After expulsion of the fetus, the placenta is expelled from the uterine cavity. This constitutes the third stage of labor.

The first stage usually begins with more or less radiating pains in the abdomen, accompanied by dull pain in the small of the back and a drawing pain in the limbs. Sometimes women with the first baby feel these pains weeks in advance of the actual commencement of labor. At first they occur at long intervals and are of short duration, but gradually become more prolonged and more frequent. The pains are due to a cramp-like contraction of the muscular apparatus of the uterus forcing its contents downward.

Under this pressure from above, the neck and mouth of the uterus distend to their limits, and the walls become thinner and thinner. First the inner, then the outer orifice of the neck of the womb opens and the fetal membranes protrude and finally rupture, allowing the amniotic fluid to escape. Shortly after this the part of the fetus nearest the orifice, normally the
head, makes its appearance. At the present time the average duration of the first stage of labor is six hours, but it may last twenty-four hours or longer, depending upon the plasticity and elasticity of the bony structures of mother and infant, the rigidity of the cervix, and the vigor or lack of vigor of the muscular apparatus of the uterus.

While the foregoing is true of the average delivery under ordinary ways of living, we find that after the enforcement of a natural regimen of living during and, better still, before pregnancy, the entire period of labor and delivery does not cover more than half an hour, or at the utmost from one to two hours. Even the disadvantages of slight build and smallness of pelvis can be overcome by the natural regimen outlined in section X. When our youngest child was born, the mother gave the first sign of pain at about midnight. I rose from bed instantly, but had not time to finish clothing when the membranes broke. Within twenty minutes after the commencement of labor the infant was resting in my hands.

The wife of a prominent lawyer in a western city had experienced three difficult deliveries. Each time surgical instruments had to be used and she had suffered untold agonies lasting from 24 to 36 hours. When she became pregnant the fourth time the most prominent physicians in her home city assured husband and wife that it was not safe for her to go through another delivery, that the womb was in worse condition than ever before therefore they recommended surgical removal. For conscientious reasons, however, the husband and wife did not follow the advice of the doctors, but decided to try natural methods of treatment.

The lady placed herself under our care during the fifth month of pregnancy. From that time on she followed strictly the natural regimen of living and received daily the usual hydropathic and manipulative treatments. This was continued until a few weeks before delivery. In this case the baby was born within an hour from the first contraction, and the mother of the patient, who was in an adjoining room, had not heard a sound. Many similar experiences refute the idea that it is unsafe and injurious for pregnant women to undergo the ordinary methods of natural treatment, such as hydropathic sprays, sitz baths, massage, Swedish movement and other forms of manipulation.

1. Preparation for Delivery. The diet during the last week before the beginning of labor should be very light, consisting mostly of fruits and vegetables. From the commencement of labor no food at all should be given, until at least twenty-four hours after delivery; a three-day fast is better.

In addition to a competent physician, a nurse or midwife should be engaged. If a good neurotherapist, who has had sufficient experience in obstetrical work, can be procured, he should be preferred, because he can assist delivery and make it much easier by manipulative treatment.
The nurse will make the necessary preparations and provide the various supplies needed in labor. With the first sign of approaching labor, the physician in charge should be summoned. A rectal enema of one pint or more of warm salt water (See. XVIII, No.4) should be administered. The woman should be given a vigorous cold rub and her genitals thoroughly cleansed. She may then remain on her feet and walk about, comfortably dressed, until actual labor commences.

2. **No Anesthetics.** The attending physician should not be impatient to hasten delivery with drugs or instruments. The use of anesthetics should be avoided insofar as this is possible. They should be employed only when absolutely necessary—that is, when excessive pain must be allayed or when surgical delivery is unavoidable.

3. **Breaking of Water Bag.** When the bag of water is about ready to break, the patient is placed in bed. Premature discharge of the amniotic fluid must be guarded against. An escape of the liquid at an early stage means difficult and prolonged labor, commonly known as "dry labor". Usually the membranes burst when the orifice is fully dilated. A large sponge is held in readiness to catch the out-flowing liquid.

3 a. **Umbilical Cord.** When the infant has been delivered, the umbilical cord should not be severed at once. Plenty of time should be allowed for the blood to transfuse itself from the body of the mother to that of the child. This is important. If the connection is severed too soon, the child begins life in an anemic condition.

The newborn baby usually greets the world with a lusty cry. It should be placed on its right side with its face turned away from the mother, care being taken that the cord is not stretched tight. As soon as the cord stops pulsating, plenty of time being allowed for blood transfusion, it is tied about two inches away from the baby's abdomen and cut a little above the ligature. The baby is now wrapped in a warm blanket and put in its crib.

4. **After Delivery.** Immediately after the baby is born, the nurse or attending physician gently compresses the abdomen and womb of the mother, kneading and rubbing it occasionally in order to secure complete contraction and thus prevent hemorrhage. After delivery the mother enjoys a period of rest and recuperation which usually lasts for about half an hour.

5. **Afterbirth.** Meanwhile the placenta becomes detached, and when the pains set in again a few contractions usually suffice to expel it with all the membranes.

The attending physician must make sure that none of it is left in the body, since this might result in putrefaction of the remains and blood poisoning. The woman's genitals should be washed with clean sterilized water.
The exhausted woman should now enjoy a deep, wholesome sleep and awaken from it in a few hours refreshed and strengthened.

In the foregoing I have not gone into the details of obstetrics and of technical management because this must be left to a competent obstetrician. I have called attention only to those points which are of special importance from the viewpoint of Natural Therapeutics and to the differences in treatment between the conventional and natural methods.

6. The Lying-In Period. The lying-in period varies from five to twelve days, according to the constitution of the mother and the care that she has taken during pregnancy. The greatest danger of the lying-in period is puerperal sepsis or blood poisoning. This condition is the result of infection occurring during labor, or it may result from the retention of parts of the placenta.

The only way to prevent this is by observing the most scrupulous cleanliness during the entire process of childbirth and during the lying-in period. When blood poisoning has developed it must be treated the same as all other acute inflammatory diseases (see section IX).

7. Care of the Newborn. The child should begin to breathe immediately after the cord is cut. If it fails to do this, the physician should lift the baby by its feet to facilitate the escape of mucous from the trachea and throat. If necessary the mucous must be removed from the throat by the insertion of the little finger, or by means of a tiny stick covered with gauze.

Breathing may be accelerated effectively by a few sharp taps on shoulders and buttocks. If this fails to bring the desired result, artificial respiration must be resorted to at once. The attendant grasps the child by its shoulders, its head resting between his palms and the two index fingers being hooked under the child's armpits. It is now swung between the physician's legs and lifted high above his head so as to be turned upside down. This is repeated from fifteen to twenty times, after which it is placed in a basin containing a few inches of warm water. Its body should then be rubbed briskly with cold water.

Father Kneipp used to take the newborn babe by the nape of the neck and the feet and submerge it quickly in cold water. This, a few times repeated, is probably the quickest way of resuscitating an asphyxiated baby.

In order to soften the cheesy deposit which frequently covers the body of the newborn, it is well to rub the skin with warm olive oil. After the greasy covering has sufficiently softened it may be removed with bits of gauze. This is followed by a cleansing bath with warm water and castile soap.
After the warm cleansing bath, the little body should be quickly rubbed down with cold water, wrapped in a soft, warm blanket and laid away to sleep until it wakens of its own accord. A normal baby should sleep for about twelve hours, and must not be disturbed to force food on it before it is ready to take it.

8. Bathing. From the first day, the baby must have a morning and evening bath. This consists, as before described, in a quick, cleansing bath of warm water and castile soap, followed immediately by a brisk cold rub. In the course of a few weeks the baby can be placed, for the cleansing bath, in a small bathtub containing a few inches of warm water. Immediately after the cleansing bath the warm water is replaced by cold water. This is taken up in the hollow of the hand and briskly applied to the little body. In this fashion the child, within a few months time, will enjoy its cold rub just as much as an adult. I have seen several such nature cure babies, but a few months old, object most vigorously to a warm bath. The cold rub is the best preventive of chilling; but care must be taken that the temperature of the room where the bath is given is not below 70 deg.

The olive oil bath or rub, often recommended for premature babies or infants suffering from malnutrition, is very injurious, because it occludes the pores of the skin and prevents the elimination of poisonous gases and other morbid materials from the body. The skin is not an organ of digestion. Olive oil, like all other foods, must enter the body through the alimentary canal where, under the action of digestive ferments, it is broken down into its component elements which are then assimilated through the intestinal membranes. Oil absorbed through the skin is not digested, and it circulates in the body as foreign matter which in this state cannot be assimilated and utilized in the system.

9. Powdering after the bath is fully as injurious as the rubbing with oils or massage creams. Powders and creams tend to clog the pores, and most of them contain poisonous antiseptics which lower the vitality of the skin and prevent or suppress elimination in the form of skin eruptions, eczemas, etc. For chafing use nothing but cold water. In case the chafing should become unusually severe and painful, through neglect by the caretaker, a soothing and healing lotion composed of one part lemon juice to two parts olive oil, may be applied a few times, until the irritation is under control.

10. Air Baths. Next to cold water, there is nothing that will invigorate baby's skin and nervous system as will the air and sun bath. If the season will not allow the outdoor air bath, the baby should be allowed to lie nude several times a day, for thirty minutes or more, in a warm, well ventilated and sunny room.

11. Constipation. Glycerin and suppositories should never be used; neither laxatives nor cathartics. Oat extract and cooling sitz baths will produce natural movements.
12. **Diarrhea** is a form of morbid elimination, and must never be suppressed by drugs. If it is habitual, bailey or wheat extract prepared in the same manner as oat extract, is a good remedy. If the diarrhea is persistent and of a violent nature, no food at all must be given, except water with dilute acid fruit juices, until the purging ceases. Even then plenty of time must be allowed for the rebuilding of the sloughed intestinal membranes.

13. **Bandages.** Until the umbilical cord dries up and falls off, it is necessary to cover the navel with a gauze compress dipped in olive oil. This is held in place by an abdominal bandage made of soft cotton material. These strips should not be hemmed, merely torn or cut. They should be drawn just snugly enough to hold the compress in place, but not tightly enough to interfere with circulation. The, navel must be cleansed and the compress renewed twice each day. After the umbilical cord has dropped off we no longer apply the abdominal bandage. This is contrary to common usage, but is the best practice. The abdominal bandage overheats the body and interferes with the free movement of the diaphragm and the circulation of the blood.

14. **Clothing.** The clothing of the infant should be loose and light and as simple as possible. Freedom of movement is very important; binding or pressure upon any part cannot help but interfere with the circulation, and otherwise produce injurious results. The clothes should be short, in order to allow the feet and legs free play. Light weight, porous cotton materials are best for both under and outer garments. A lightweight wool petticoat may be worn when absolutely necessary to provide sufficient protection for the baby. Cotton hose and bootees may be used, but under no circumstances should such articles be of wool, because it prevents free elimination from the skin. The baby's head should not be covered out of doors, except in severe weather. At no time should a veil be placed over the face, as it will cause the infant to reabsorb the poisonous exhalations from its own lungs. All clothing should be changed each day. No garment should be starched—such a practice is not only useless but harmful.

15. **Diapers** must be provided in sufficient number to allow thorough cleansing and drying. The wet diapers should be scalded in hot water and very thoroughly rinsed in several waters afterwards. They should then be dried in the open air and sunshine. Soiled diapers must be well washed and boiled. Washing powders, soda, ammonia and other chemicals should never be used. They have an extremely irritating effect upon the delicate skin of a baby. In order to save labor and to facilitate the cleansing of the diapers, small squares of clean old linen or muslin rags, or pieces of absorbent gauze, may be placed inside. These inserts will absorb all or most of the bowel movement and may then be burned. If the skin is irritated or chafed, the parts should be sponged off with clean cold water at each change, paying special attention to cleansing of the genitals. Oils or powders must not be used to soothe the sore places, because they clog the pores and
Interfere with natural elimination.

16. A wet nurse is to be preferred to artificial feeding. She should be thoroughly healthy, not over thirty years of age, of equitable temper, not excitable or nervous and her diet should be that prescribed for the mother.

17. Care of the Nipples. They should be thoroughly cleansed before and after nursing; not with carbolic acid, but with water and dilute lemon juice. The lemon juice tends also to harden the nipples. Treatment of the nipples may begin before the birth of the child.

18. Care of the Eyes. The baby's eyes, whether awake or asleep, should always be shielded from strong light, either sun or artificial, and from dust and wind. The eyes should be washed with cold water after every cleansing bath. If they show any tendency to weakness or disease, slight vibratory massage over the closed eyelids should be given after the cold eye bath.

19. Care of the Mouth. A healthy baby's mouth needs no cleaning before the arrival of teeth. As a matter of fact, the teeth of a perfectly healthy adult would not need cleaning any more than do those of an animal living in the freedom of nature. The saliva is a sterilizing fluid, under normal living, intended by Nature to keep the mouth clean and healthy. Cleansing of the mouth of an infant with the finger or with a cloth may injure its delicate membranes. If the mouth must be washed, in case of disease, a swab made by twisting a piece of sterilized absorbent cotton on the end of a smooth stick should be used. The swab should be dipped in warm boiled water, and the interior of the mouth washed thoroughly, the cotton then being burned.

20. Care of the Ears. The external ear should be cleansed with a soft rag or swab as before described. Never use a hard instrument inside the ear.

21. Care of the Nose. A baby's nose should be cleansed as a part of the daily toilet, in the same way as the ears. A swab may be made by twisting a, piece of gauze to a cone. As soon as the child becomes old enough, it should be taught to sniff up cold water through the nostrils and the nasal passages. This is the best way to keep the nasal membranes in a clean, healthy condition.

22. Care of the Genital Organs. The genital organs of both sexes must be kept scrupulously clean with as little handling as possible. The foreskin of the penis of the male baby should be drawn back at bathing time and the organ thoroughly cleansed, always finishing with cold water.

23. Phimosis. The treatment of phimosis is fully described under Sec. XXVIII, No.1.

24. How to Lift the Baby. The best way to lift a young
baby is to slip the left hand under the back beneath the shoulder, spreading out the fingers in such a way as to support the neck and head. Then lift the feet and legs with the right hand. *Never lift an infant without first supporting the spine.*

When a baby has grown strong enough to hold up its head and has gained considerable strength in the muscles of the back and neck, he may be lifted by grasping him with outspread fingers under the armpits; the body must be held firmly so that the entire strain does not come on the shoulders. A baby should never be lifted by the arms. This may dislocate the shoulder joints.

---

**SECTION XXXVIII**

**Prenatal Feeding**

1. **Effects of Diet During Pregnancy.** The problem of infant nutrition begins before birth. Prenatal feeding determines the physical start in life. On it depends not only the condition of the mother's health during pregnancy, but also the size and weight of the fetus, pliability of the bony structures, ease or difficulty of delivery, and the quality of the mother's milk.

   The flesher and heavier the newborn infant, the prouder and happier are the parents and the doctor. Yet, excessive size and weight of the child constitute the most prominent cause of difficult and painful childbirth and frequent necessity for instrumental delivery.

   The biblical saying, "In sorrow thou shalt bring forth children"; has led many to believe that woman's dreadful suffering is a necessity, God ordained; but is not man's ignorance, rather than the cruelty of an avenging God, to blame?

   This latter view is confirmed by the fact that other mammalia literally cast their young, without pain or difficulty; and the labor pains of primitive mothers are insignificant, their delivery presenting little more difficulty than that of the lower animals. A squaw on the Western Plains stops a few hours by the wayside to deliver her papoose and then resumes her journey as though nothing had happened.

   Women among the European peasantry, who wear no corsets, live on black bread and vegetables, and have plenty of exercise in the fields and in the home to the last day of pregnancy, have their babies without help of midwife or physician and resume their usual routine of work within a few days after delivery.

   Thousands of mothers who have adopted natural ways of
living have learned to dispense with anesthetics and the surgeon's instruments; they now bring forth their offspring without excessive pain.

2. Results of Faulty Diet. It is significant that the offspring of the lower animals, at birth, consist of little more than skin and bones, while the newborn human is often abnormally large and fat. This is especially true of babies born of weak and anemic mothers. As before stated, excessive size and weight of the infant is not a matter for congratulation, but is a pathological condition. It indicates fatty degeneration of the fetus, due to the anemic watery condition of the blood of the mother, and the cause of this hydremia of mother and child lies in the faulty dietetic habits of the former.

The ordinary diet of American women consists almost entirely of meat, fish, fowl, potatoes, white bread, pastry, coffee, tea and refined white sugar. The few vegetable, which enter into the daily dietary are first deprived of their all important organic salts by faulty cooking; fruits are looked upon as luxuries and frequently are regarded as harmful

The anemic, watery condition of the blood of mother and child is not due to a lack of starchy, protein and fatty materials in food and blood, but to a deficiency of organic mineral elements. Neither is the anemic condition, as the regular school of medicine assumes, caused by lack of iron. Any ordinary food mixture, as well as the blood and milk of anemic mothers, usually contains a sufficient amount of iron. The actual cause of the anemia is a deficiency of other mineral elements.

As I have explained in Volume III of this Series, carbonic acid poisoning and the resulting sluggishness of the surface circulation, coldness of the extremities and congestion of the inner organs is not caused so much by a lack of the oxygen-carrying iron as by a deficiency of the carbonic acid neutralizing and eliminating sodium and magnesium.

If the blood is deficient in lime, phosphates, silicon and fluorine, rachitic conditions, softening of the bones, deformed spines and legs, and decay of the teeth, are inevitable results.

It is an easy matter to supply the daily needs of the organism for proteids, starches, fats and sugars; the difficulty lies in supplying a sufficient amount of the organic mineral elements.

The deficiency of sodium in human blood, Dr. Lahmann proved in the following table of comparative blood analyses. In a hundred parts of ash he found in the

<table>

Blood of dogs | 2.02 to 5.78
Human blood | 2.03 to 6.27

The percentages of lime and of other positive mineral elements in the human blood are also much lower than in the blood of cows, oxen and sheep.

While the blood of cattle and sheep raised on pasture is very uniform in composition, hardly any two samples of human blood are alike. It is for this reason that Dr. Lahmann adopted cow's milk instead of human milk as the standard elementary food combination.

In the following table, he compares the percentages of minerals in the ash of cow's milk with the percentages of mineral elements in the ash of various other food materials.

A daily dietary consisting largely of meats, eggs, white bread, potatoes, peas and beans, though excessively rich in proteids, fats and starches, will, on account of its deficiency in sodium, lime and magnesium, inevitably result in carbonic acid poisoning, anemia, rachitis, premature decay of the teeth and a multitude of other acute and chronic ailments.

If, however, the daily dietary contains a liberal amount of green vegetables and fruits, a normal food mixture resembling that of cow's milk can easily be obtained. It must be remembered that fruits and vegetables are not only rich in the most important mineral salts, but that they are relatively poor in proteids and carbohydrates.

For this reason fruits and vegetables facilitate the establishment of an equilibrium between proteids and carbohydrates on the one hand and organic mineral salts on the other.

3. **Excessive Fat Formation.** We can now understand why the ordinary faulty diet of pregnant mothers causes anemia, softening of the bones, sluggish circulation, carbonic acid poisoning and fatty degeneration in mother and offspring.

Lack of sodium causes excessive accumulation of carbonic acid, and oxygen starvation. This results in defective
oxidation of food and waste materials; in other words, in fat formation.

Defective draft prevents the complete consumption of coal, and chokes the furnace with the products of imperfect combustion. Similarly, lack of oxygen in the tissues (due to carbonic acid poisoning) causes an incomplete combustion of food materials and waste products, resulting in fat formation and in the generation of poisonous byproducts.

Lack of sodium also prevents the neutralization and elimination of uric and other acids and ptomaines (pathogenic matter) which accumulate in the tissues, block the circulation and assist in the smothering of the vital processes.

In order to eliminate these pathogenic materials, there arises an abnormal craving for water—"the anemic thirst"—which is closely related to the thirst of fever patients and of diabetics. Excessive water drinking is encouraged by the popular "flushing" fad.

To make things worse, the anemic, for reasons before stated, usually suffers from weak heart action and sluggish circulation. This means defective elimination of water through the skin and kidneys, resulting in a watery (dropsical) condition of the tissues and fatty degeneration.

Not all anemic, carbonic-acid-poisoned mothers, however, develop a tendency to obesity. On the contrary, under certain constitutional conditions, they may become exceedingly lean, like the anemic, carbonic-acid-poisoned consumptive. Briefly stated, sluggish heart action and weak kidneys favor retention of carbonic acid and water in the tissues and thus make for fatty degeneration. Good circulation and normal activity of the kidneys may keep the system free from excess of water and carbonic acid, but excessive proteids in the diet may result in sulfuric and phosphoric acid poisoning. These destructive acids break down the tissues, rob them of their mineral constituents, and thus cause excessive loss of flesh and fat.

In both types of dysemia the blood of the pregnant mother is overloaded with poisonous gases, waste matter and the debris of broken-down tissues. The oxygen supply to the fetus is therefore very much impeded and we find that both fleshy and lean mothers produce babies of abnormal size and weight, ranging from eight to twelve pounds, while the normal weight of the newborn should not be more than six pounds.

4. Advantages of Natural Regimen. We know of many instances where mothers, after having given birth to heavy, fleshy babies, in subsequent births have reduced the weight of the new born to normal, and the pain of delivery to a minimum, by the adoption of a natural diet, plenty of exercise in the fresh air and systematic deep breathing.
The effects of a natural regimen are manifested in various other ways. The bony and muscular structures of mother and child are much more pliable and elastic, making parturition and delivery much easier. Pure blood, normal nutrition and abdominal exercises, walking and special gymnastics, greatly strengthen the abdominal and uterine muscles, thus facilitating expulsion of the fetus.

The morning cold rub, systematic deep breathing and general exercises, every day outdoor walks and right mental and emotional attitude are all of paramount importance in the regimen of pregnancy.

The Regimen for Wholesome Living, section I, is admirably adapted for all the needs of the pregnant mother.

SECTION XXXIX

Postnatal Feeding

Thanks to the educational influence of nature cure propaganda, a decided change for the better in baby feeding has taken place during the past ten years. Up to that time the "top cream mixture" was universally recommended by allopathic physicians and given to babies by trained nurses.

While in the meantime many physicians and nurses have adopted more natural methods, the "top cream mixture" is still too common and must be entirely abolished in order to safeguard the health of our little ones.

In the February, 1909, issue of the Nature Cure Magazine, I commented upon this subject as follows:

1. Bottle-fed Babies. Our food analyses disclose the interesting fact that the elementary composition of the ash of the milk of an animal is about the same as the composition of the ash of its body.

They also show that good cow's milk when normal comes closer to the requirements of the infant body than does inferior human milk.

Our tables of food analyses show that chemically the composition of cow's milk and of human milk is very much the same. Human milk contains a little less proteid and a little more sugar than cow's milk, and the latter is much richer in organic salts than the former. There is much more of the all-important sodium in cow's milk than in human milk and about twice as much calcium (lime) and iron (table p.100). This explains why rachitis is so common among babies, while never found among calves.

As we have learned, the elimination of poisonous acids
from the body depends on sodium. The building of the bony structures depends on lime; the oxygenation of the blood, on iron.

Many years of practical experience in the care of babies has convinced me that milk fresh from a healthy cow is greatly to be preferred, as nourishment for infants, to the impoverished milk of scrofulous mothers.* In this connection it is significant that one-half of all "civilized" mothers, thanks to unnatural food and drink, vaccination and poisonous drugs, are incapacitated for nursing their offspring.

* This may not be true in the future if our milk cows continue to be regularly subjected to tuberculin tests.

To one who has studied the comparative analyses of cow's milk and human milk, it is incomprehensible why the former, when given to infants, should be diluted and spoiled by large quantities of water, salt, soda and inorganic mineral lime (in the form of lime water).

This procedure, however, is still frequently recommended by physicians of the regular school. Undoubtedly, the great frequency of anemic and rachitic diseases, the darkening of the iris, appearance of scurf rim, and the signs of catarrhal conditions in stomach and bowels are caused by such unnatural feeding.

The following extracts are taken from an article entitled "Bottle-fed Babies", in the Ladies' Home Journal. It was written by Dr. Emelyn Lincoln Coolidge, of the Babies' hospital, New York. Thousands of mothers, on account of the high standing and excellent reputation of this family journal, undoubtedly have followed, without question or misgiving, the advice presented.

The formulas given below are for the average healthy baby, and are called "cream" or "top milk" mixtures.

"Food for the first month. With a spoon, or a tiny dipper which comes for this purpose, carefully skim off the top six ounces from a quart bottle of milk; to this add twenty-four ounces of water which has been boiled and cooled, and in which has been dissolved three teaspoonfuls of granulated or six of milk sugar; next add a pinch of bicarbonate of soda and a small pinch of salt; mix this all thoroughly, and pour enough for each feeding into ten separate bottles. Then cork the bottles family with cotton and either Pasteurize the milk or stand it on the ice.

"For the second month. Skim off six ounces of cream, then pour off three ounces of milk; add twenty-four ounces of water and the same amount of sugar, salt and soda as above; mix and bottle.

"For the third and fourth months. Cream, six ounces; milk, six ounces; water, twelve ounces; barley or oatmeal gruel, twelve ounces; sugar, salt and soda as usual, etc.

Plain Milk Formulas

"Pour the entire quart of bottled milk out into a clean pitcher and then back into the bottle several times, thus thoroughly mixing the milk; then take:
"For the first month. Six ounces of milk, twenty-four ounces of barley-water, half a tablespoonful of granulated or one of milk sugar, a pinch of bicarbonate of soda; mix all well together and pour the proper number of ounces into separate bottles, and either Pasteurize or place on ice.

"For the second month. Nine ounces of milk, twenty-one ounces of barley-water, one tablespoonful of sugar, and a pinch of soda."

Physicians would never think of giving such advice as this, if they were acquainted with natural dietetics founded on exact and complete analyses made by food chemists of the nature cure school.

I have already called attention to the fact that food chemistry, whether practiced in allopathic colleges, in great sanitariums or by vegetarian food reformers, deals with proteids, starches, fats and sugars only, and leaves entirely out of consideration the all important mineral elements or organic salts of potassium, sodium, iron, lime and magnesium.*

*This was true at the time this article was published in the Nature Cure Magazine.

On these five positive mineral salts, as we have shown, depend all the important vital functions of the human organism, while proteids, starches, fats and sugars serve only as building and fuel material.

The digestion of the proteid and carbohydrate foods, as well as the elimination of the waste matter resulting there from, depends upon the positive organic mineral salts.

Study carefully these recipes for baby feeding, taken from the Ladies' Home Journal, and compare the mixtures with the analyses of cow's milk and human milk in the accompanying tables.

Let us consider the "top milk" mixture, prescribed for the first month. The cream rising to the top is almost pure fat. The all-important mineral elements plus the nourishing milk sugar and proteids remain in the skimmed milk, which is looked upon as worthless and fed to the pigs.

Our food analyses (see tables in Volume III, Cook Book) show that the ordinary brands of flour are almost devoid of mineral elements. Furthermore, one teaspoonful of barley to one pint of hot water does not mean much in food values. Where in these six ounces of cream (fat) and twenty-four ounces of barley water is baby to get the necessary amount of sugar for fuel material, of proteid for tissue-building, of lime for bone-building, of iron for oxygen-carrying, and of sodium, magnesium and potassium for the processes of elimination?

It seems that these deficiencies are intended to be overcome by baking soda, mineral table salt and the lime water, so generally prescribed by physicians. Many times I have demonstrated that inorganic mineral salts, with the possible exception of a little table salt, should not enter the animal or human organism, that these salts must first be organized,
made alive in the plant or animal cell, before they are wholesome food for animals or human beings. I have shown that, taken habitually in the mineral form, these salts accumulate in the human body, act as irritants and poisons and reveal their presence in the iris of the eye.

I fail to understand why the tender and sensitive organism of the newborn infant should be encumbered with inorganic minerals while cow's milk contains them in ideal form, made alive first in the grasses and grains, then still more highly organized and magnetized in the body of the animal.

It is bad enough to give mineral sodium, lime and table salt to an adult, but it is little short of criminal to give them to babies under the guise of foods and medicines.

The cream mixtures are readily digested, because there is not much to digest. The fact that infants thus fed cry for food continually is good evidence that their needs are not satisfied. Babies fed with this sort of slop grow fat for a while. The watery food inevitably produces fatty degeneration. This for a season swamps the little body with unhealthy fat. But the first crisis which happens along often takes away not only the unnatural fat, but the baby also.

The artificial mixtures contain entirely too much water in proportion to nourishing elements. The resulting malnutrition and the constant irritation caused by the inorganic minerals result in chronic diarrhea or constipation.

**The Right Way**

The best food for the newborn and growing infant is undoubtedly the mother's milk, provided that she is herself in fairly good health. Unfortunately, many mothers are unable to nurse their offspring, and if a healthy wet nurse cannot be secured, other food must be provided.

The best substitute for human milk, without question, is cow's milk, fresh, pure and undiluted, as it comes from the animal.

"Why", indignantly exclaims the trained nurse, when we give these instructions, "undiluted cow's milk is altogether too rich, it is indigestible for baby; if the milk is not boiled or pasteurized, germs and bacilli will surely create infectious diseases".

To this we answer: Our analyses show that the difference in composition between cow's milk and human milk is not enough to affect the infant. The danger lies not so much in overfeeding on "rich" cow's milk as in underfeeding on watery milk and cereal dilutions, and in poisoning the little body with inorganic minerals.

As regards germ infection and the necessity for pasteurizing the milk, the menace to health and life is greater through
malnutrition than through germs and bacteria. Germs we cannot escape, not even if we were surrounded on all sides by walls of air-purifying and antiseptic materials.*

*Since the foregoing was written we have learned that low vitality and morbid soil will develop perfectly normal microzyma into so called disease germs.

One of the foremost French bacteriologists claims that in the mouths of infants shortly after birth he has found almost every disease bacillus known to medical science.

William Osler; M.D., to whom the English language is indebted for the verb "to oslerize," says in *The Principals and Practice of Medicine* on page 151, in the chapter on Diphtheria:

"The presence of the Klebs-Loeffler bacillus is regarded by bacteriologists as the sole criterion of true diphtheria, and as this organism may be associated with all grades of throat affections, from a simple catarrh to a sloughing, gangrenous process, it is evident that in many instances there will be a striking discrepancy between the clinical and the bacteriological diagnosis."

In the first part of this sentence he states that bacteriologists regard as the sole criterion for the diagnosis of diphtheria the Klebs-Loeffler, or diphtheria, bacillus; in the last part of the sentence he admits that this bacillus is found in even slight catarrhal conditions, and he might add that it is found just as frequently in the mouth and throat of healthy infants and adults. This is a good example of "orthodox" scientific reasoning.

If germs and bacilli of themselves could destroy health and life, the human race would in a short time become extinct. Disease germs are omnipresent. They permeate the tissues of our bodies and in the intestinal tract swarm by millions. Whether they prevail depends upon natural resistance, or reserve force, and upon the disease soils in the system. The air we breathe is saturated with all sorts of disease germs or their microzyma.

Since baby cannot escape germ invasion, the real problem is how to increase the resistance of the little organism and how to purify it of morbid matter so that disease germs will not find anything to feed on.

Resistance depends largely upon proper nutrition. Diluted, watery milk, contaminated by inorganic minerals, is not a good nutrient; its nutritive value is still more reduced by pasteurizing or boiling. Heating milk or any other proteid food above 1500 F. coagulates the albumen, disorganizes organic compounds, precipitates salts and dissipates the life elements. This reduces the nourishing value and digestibility of the milk.

Nature does not provide the young animal with boiled or
pasteurized milk, and we should not lower food values by such methods.*

* It is now admitted that pasteurization and boiling kills "newly discovered vitamins" which are the "life elements" constantly referred to in my earlier writings.

I do not wish to intimate, however, that scrupulous care and cleanliness should not be exercised in the selection and handling of the milk.

Wherever possible, secure the milk of a single healthy cow that grazes on green pastures or is fed on normal clean food mixtures. Milk from cows kept in stables and fed on brewery and distillery slops and other refuse should not be used.

Every vessel and utensil with which the milk comes in contact must be carefully scoured, submerged in boiling water, drained and kept in a light, airy place.

The nursing bottle, after each feeding, must be taken apart and carefully scrubbed, inside and out, in hot water with an addition of a little soda. It should then be left in pure, cold water, until the next feeding time.

2. When to Feed. Physicians quite generally recommend feedings at stated hours, in fixed quantities.

This is altogether wrong, it establishes at once the stuffing habit, does not permit the development of natural desire and its regulation. The infant very soon becomes accustomed to eating at certain times, whether it really needs the food or not.

Food should not be given until there is an actual demand for it, which will express itself in real hunger. By careful observation and experiment the mother will soon learn to distinguish the ordinary crying of the baby and the desire for food expressed by it. If this practice of feeding only when there is a natural desire for food is strictly followed, the infant will soon establish its own regular feeding times, usually at intervals of about three or four hours in the daytime. The stomach digestion of a feeding of milk will require about three hours, therefore a minimum of that much time should be allowed between feedings after the first few weeks.

If the mother can nurse her baby, it should be put to the breast upon awakening from its first sleep, either before or after bathing and dressing.

The first secretion of the breasts (colostrum) is not really a food, but performs an important function in cleansing the intestinal tract and preparing the digestive system to properly digest and assimilate the milk when it comes, usually about the third day.

3. How to Feed. If artificial feeding must be resorted to, no food at all should be given, except a few teaspoonfuls of water, during the first twenty-four hours after birth. During
the next few days, cow's milk should be given, well diluted—about one-half milk and one-half filtered or boiled water. From week to week the amount of water should be reduced until at the end of the second month the baby takes cow's milk undiluted.

4. Night Feeding. In the nighttime feeding should not be encouraged. During the first four months it is advisable to feed not more than once during the night. After that the child should be weaned from the habit entirely. This will be facilitated by giving a drink of water instead of milk.

5. Amount of Food. Discretion should be observed in determining the amount of food. Do not induce the baby to take as much as possible, rather as little as possible. Its welfare does not depend upon the amount of food consumed, but upon the amount which it can easily digest and assimilate.

When more food is given than the digestive organs can take care of, the entire mass may ferment and sour.

6. Grain Extracts. If undiluted milk proves too rich, grain water may be added. In order to prepare this, take clean grain as it comes from the field, crush it in a hand grain mill or a new coffee mill, take three tablespoonfuls of the crushed grain to one pint of cold water, and boil on the stove for one hour; or in the fireless cooker for two or three hours, in which ease use a little more water at the start. While the gruel is boiling over the fire, add enough water to allow for evaporation and absorption. When thoroughly cooked, strain the gruel through a fine cloth or sieve. Add one tablespoonful, or more if necessary, to each milk feeding.

When baby is constipated, add to the milk, grain extract made from oats, and frequently cool the bowels with cold water. This will cure the most stubborn constipation. If the bowels are too loose, add to the milk, extract made from barley or wheat.

The small particles of hulls in the grain extracts improve digestion and evacuation, in a mechanical manner. They permeate the curds and keep them from coagulating too solidly, thereby facilitating the penetration of digestive juices; they also exert a mild stimulation on the walls of the intestines, thereby increasing the peristalsis of the bowels and evacuation of feces.

7. Baby's Natural Medicines. Fruit juices and scraped raw ripe pear or apple and the pulp of cooked fruits such as prunes or figs without addition of sugar or sweetening of any kind, are baby's finest medicines. They increase the supply of organic salts for blood, nerve and bone building and for purposes of elimination. They are nature's own cholangogues, laxatives, tonics and antiseptics. They keep the little body sweet and wholesome. All babies under our care receive fruit juices beginning with the second week.
During the first two months, give one teaspoonful of orange juice, grape fruit juice or prune juice, one hour before or after each nursing. After the second month, gradually increase the amounts of fruit juices and begin to add raw pear or apple scraped with a spoon or dull knife, or the mashed pulp of fully ripened peach or grapes.

8. Weaning the Baby. Nursing infants should be weaned from the breast after the eighth or ninth month. From the sixth or seventh month, both nursing and bottle-fed babies should begin to take some solid food. The best of these to begin with are whole-grain cereals, gruels, raw and cooked fruits and tender vegetables in small amounts. Mealy baked potato is one of the best foods, better than the cereals.

9. Feeding After First Year. After the lapse of the first year, the solid foods are gradually increased and the milk reduced in quantity. Eggs should not be given before the eighteenth month, then soft-boiled or poached. During the second and third year half an egg twice or three times a week is sufficient; after that an egg at a time may be given once or twice a week.

Meat and all other foods prepared from the dead animal carcass are bad enough for adults, but it is inexcusable to give them to tender infants and children.

Dog fanciers, when they sell a valuable canine, usually advise the buyer not to give the animal any meat before the second year, lest it become a victim of distemper; and dogs are naturally meat eaters.

Well informed physicians now generally advise not to give meat to children before the fifth or sixth year. They have learned this much from the nature cure people.

Foods undoubtedly have a powerful influence, not only on the physical body, but also on the mentality and the emotions. These problems will be interesting subjects of investigation for the food chemist and psychologist of the future. In general, we may say that flesh foods are stimulating and feed the passional nature, while fruits and tender vegetables refine and stimulate brain and nerve matter as well as the intellectual, emotional and spiritual activities. Cereals, nuts and pulses build and repair the physical body and supply the body with heat and muscular energy.

The majority of animals adhere strictly to one kind of food, and therefore faithfully exhibit in their mental and emotional characteristics the effects of different food materials. Ferociousness we find personified in the carnivorous bulldog, lion, tiger and panther (that is why soldiers are fed on meat three times a day); glutony and omnivorous voraciousness in the hog, chicken and hyena; cold-blooded cunning in the fox, and cruelty in the cat. The intelligence of the carnivorous animals displays itself mainly in the cruel cunning with which they stalk their living prey. It resembles in quality the low
intelligence of the human criminal.

Personifications of great physical strength, intelligence, endurance, patience, gentleness, fidelity, affection and self-control, we find among the vegetarian animals. The beaver, the arboreal ape and the elephant are especially noted for their intelligence; deer, antelope and sheep for gentleness; the horse for its almost human intelligence, affection and fidelity. Oxen, elephants and camels for their great strength and endurance.

**Meat is detrimental to the child in every way**, physically, mentally and morally. The poisonous acids and alkaloids which it contains clog the capillary circulation, causing anemia, coldness of the extremities and defective elimination through the skin. This results in congestion in the interior organs, high blood pressure in brain and heart, headaches, nervousness, irritability, tendency to fevers, inflammations and catarrhal conditions.

With the meat, the child often absorbs the eggs of worms, tubercular bacilli, and other parasites and disease germs. Certain forms of epilepsy, St. Vitus' dance and hysterical conditions are due to uric acid poisoning and to other pathogenic materials and ptomains contained in flesh foods. Such patients, in times of crises, frequently emit pronounced odors of raw meat or uric acid. Strictly vegetarian diet, combined with other eliminative natural methods of treatment, cures the majority of these cases.

Most of these poisonous acids, alkaloids and ptomains contained in the flesh of dead animals are powerful stimulants. I have frequently noticed that people who have abstained from meat for a long time, when they first partake of it again experience sensations and exhibit symptoms resembling those of alcoholic intoxication.

We have learned that these stimulating extractives of flesh foods chemically closely resemble caffeine, thein and nicotine. The use of one or more of these stimulants invariably creates a craving for the others. This explains why a heavy meat eater is usually a confirmed coffee drinker or inveterate smoker, and vice versa; and why we find it almost impossible to wean people from one of these stimulants as long as they persist in taking the others.

The legumes or pulses—peas, beans and lentils—are close seconds to meat in acid-producing qualities. Eggs contain considerable ready-made uric acid and a great deal of sulfur and phosphorus. These may become dangerous to the organism. For these reasons, meats, legumes and eggs are always danger foods for the child.

Children brought up on such foods will show the effects in nervousness, irritability, lack of self-control, craving for cigarettes and alcoholic stimulants. The most serious aspect of this question lies in the stimulative influence of meat poisons
on the sex centers. It is a well known fact, verified by close 
observation, that flesh foods stimulate the sexual passions to a 
marked degree. This tendency is greatly increased by the use 
of coffee, tea and alcoholic stimulants in the form of wines, 
liquors or medicines. If the sensitive nervous organism of a 
child is overwrought by these powerful irritants, there can be 
but one result; precocious sexual awakening.

From the third year the child may gradually adopt with 
slight appropriate modifications, a diet as outlined under Sec. 
I, No. 10, and Sec. X, No.7.

SECTION XL

Exercises in Infancy

1. Exercises in Infancy. Proper exercise is important from 
the very beginning of life. A baby will follow its natural 
instincts for exercise if allowed to do so, by working its arms 
and legs and writhing its little body in all directions, if not 
unduly hampered by tight clothing and bandages. A few nude 
air baths every day will afford excellent opportunity for 
baby's gymnastic stunts.

After he is a few months old he may be placed on his 
stomach, when he will exert himself vigorously by trying to 
raise his head, to turn around, or to raise himself with his 
arms. He will soon learn to roll over and to creep lie nay now 
be pulled up gently by his arms and lowered again a number 
of times in succession.

When three or four months old he may be lifted by one arm 
or by both arms; by the right arm and left leg, or by the left 
arm and right leg. When the baby is six or eight months old, 
he should be strong enough to rise from his back to a sitting 
position. This may be encouraged by holding down the feet. I 
have known a number of nature cure babies who at six 
months of age clung tightly to a stick while being lifted a few 
feet from the bed. Another good exercise greatly enjoyed 
by the youngsters is to roll them back and forth on a bed.

The average healthy child will secure ample exercise while 
learning to walk and run and while playing with simple toys 
or with other children; but this may be supplemented to good 
advantage by special exercises devised by the father and 
mother. Nothing is better for the health and happiness of both 
parents and children than to join in merry romp and play.

Between two and five years of age the child may be taught 
more difficult stunts, performed either by himself or with the 
assistance of the father or mother; but swinging the child 
high overhead, throwing him up and catching and other 
dangerous tricks should be avoided. They are risky and 
have very little effect in developing the body of the child. The 
best exercise at this age consists in outdoor play and games.
From the sixth year, the question of exercise becomes a more important one, especially since the children are confined for many hours in school rooms. If exercise at this time of life, through play and games and special gymnastics, is neglected, it may affect health, strength and efficiency of the child for life.

Those of good physique and ample strength may gradually take up and practice the exercises for adults outlined in sections XXI, XXII, XXIII, XXIV.

2. High Chair. A baby should not be put in a high chair until he is quite well able to hold the spine and head erect, and should never be left in a chair for any length of time. If a baby is forced to maintain a rigid, sitting position for a considerable time, before the bones and muscles are sufficiently developed, this may produce deformity of the spine. Maids and nurses, if not properly supervised, sometimes fasten a baby in a high chair and leave him there to take care of himself for long periods.

3. Toys. Since most babies have a habit of putting everything into their mouths, toys must be selected that can do no harm. They should have no paint, no sharp points or corners which might hurt the eyes or mouth, and must be of material which can be easily and thoroughly cleansed. Hairy and woolly playthings are unsafe, being unclean and germ carriers. Objects small enough to be swallowed must never be put within baby's reach. The simpler the playthings the better; a few clothespins, empty spools, or other simple objects are better than expensive toys.

SECTION XLI

Baby's Ailments

1. Hernia. As a result of a weakly or sickly condition of the mother during pregnancy and of faulty prenatal management, many children are born ruptured. So far I have not known a single nature cure baby that was born ruptured. Such defects are due to weakness of the tissues. This results from mineral starvation. The tissue walls contain too much mortar (protein) and not enough building stone (mineral salts). Prevention of hernia, therefore, lies mainly in proper diet of the pregnant mother, but all the rest of the prenatal regimen described in these pages is of great importance in preventing this and other ailments and deformities.

There are three principal points at which rupture or hernia may take place in infancy-at the navel, in the groin, and at the line between the navel and the lower end of the sternum. Other kinds of ruptures are extremely rare.
2. **Umbilical Hernia** This is a protrusion of the intestine at the navel. It is the most common rupture in infancy. Pulling on the cord during childbirth, urging at stool or violent crying may result in rupture. The umbilical ring first expands and this forms a pouch into which one of the folds of the small intestine protrudes.

   Treatment: Of primary importance is the diet as outlined herein. The baby must have plenty of fruit juices in order to reinforce the mineral salts in the milk. Cold bathing is very beneficial. The rupture itself should be cleansed several times a day with warm water. This must be followed by a wash with cold water mixed with lemon juice. Gentle, passive exercise, such as raising, lowering and twisting the limbs from side to side, also raising and lowering the body while supporting the shoulders and head, is of especial value.

   The rupture must be reduced and kept from protruding by placing over it a large button or other article of similar shape, wrapped in gauze and held in place by broad strips of adhesive plaster. The adhesive tape is fastened over the button crosswise and must be applied in such a manner as to draw the skin from all sides over the rupture. Instead of the button, a compress made of gauze may be laid over the rupture and held in place by one broad adhesive strip. The covering of the rupture must be removed and renewed every day in order to allow cleansing, as before described.

   When the child is old enough to exercise by himself, he should be taught special movements of the body and the limbs which develop the muscles of the abdominal region.

3. **Ventral Hernia.** This occurs along the middle line of the body between the navel and the breastbone, sometimes below the navel. The rupture may not be larger than the size of a pea or small marble, and may disappear on pressure. The treatment is the same as that of umbilical hernia.

4. **Inguinal and Scrotal Hernia** occur in infancy or in adult life; sometimes the inguinal canal does not close after the descent of the testes from the abdominal cavity into the scrotum, and the intestine descends through the open canal, thus producing the rupture. These forms of hernia become aggravated by coughing. They can be reduced immediately with gentle manipulation while the patient is lying on his back. This kind of rupture may be distinguished from hydrocele by the fact that in reducing it goes back easily with a gurgling sound. Hydrocele is not affected by coughing. A hernia is opaque to transmitted light; hydrocele, transparent.

   These ruptures should be protected with a well-fitting truss. This has to be removed daily for cleansing of the parts. Appropriate exercises, passive and active, together with cooling sitz baths and washes with cold water and lemon juice are the best remedies for these, as well as of other forms of rupture.
5. **Congenital Hernia** occurs in the form of inguinal hernia and has to be treated in the same way. Ruptures of any kind must be reduced and properly supported. Constipation and consequent urging at stool may cause or aggravate any form of hernia and must, therefore, be overcome by the right treatment described under section XXVI, No.1.

6. **Colic.** This is usually caused by indigestion due to overfeeding, improper feeding, or too frequent feeding. The intestines are distended with gas, giving rise to a severe pain. The baby cries sharply, alternately drawing its legs up to the body and kicking them away. One of the quickest means of relief is a small enema of warm water and gentle circular massage of the abdomen from right to left. Food should be withheld until the symptoms have disappeared. The giving of milk or other food may quiet the attack temporarily, but the pain is apt to return with greater intensity. Warm water may be given if the baby will swallow it.

A baby managed in the natural way prenatally and postnatally is not likely to suffer from this ailment. Constipated babies are more prone to it than others.

Colic may also be caused by sudden chilling. In that case a warm bath for five or ten minutes, followed by gentle body massage will bring about a warm reaction.

7. **Convulsions.** These cause a great deal of anxiety to the fond mother. They are always reflex symptoms of some slight or serious internal disturbance due to wrong management. They commonly result from some form of auto-intoxication caused by digestive disturbances, and the resulting systemic or drug poisoning. An inactive condition of the skin, bowels or kidneys will favor auto-intoxication and convulsions. If proper care is taken to keep the system pure, and the organs of elimination in active condition, convulsions will not occur.

The best treatment during an attack is a quick, cold rub all over the body; application of a whole body or trunk pack; gentle soothing magnetic massage, and neurotherapy treatment. These treatments draw the blood into the surface and relieve congestion in the brain and nervous system.

8. **Ailments of Teething.** Many ailments of children are laid to teething, but this is a mistake. Well managed, healthy babies go through the teething period without any trouble whatsoever. This is practically always true of nature cure babies. When, however, the little body is heavily encumbered with hereditary and acquired morbid materials, food poisons and disease taints, the process of teething will not run its natural course and may precipitate any form of disease crisis.

When teething is difficult, it is frequently associated with digestive disturbances. Diarrhea may alternate with constipation and vomiting is of common occurrence. The baby may be restless and fretful. He tries continually to bite on something in order to facilitate the projection of the teeth
through the hardened gums.

No teething lotions or soothing medicines of any kind should be given for the relief of pain in teething. They all contain poisonous sedatives which benumb and paralyze the nerves and have serious after effects upon the system. They usually contain opium in some form, or other narcotic drugs.

The only way to prevent these and other infantile ailments is to keep the little body as nearly normal as possible through the natural treatment described in these pages. If this is closely adhered to, it will prevent, in many cases, the development of even measles and other common eliminative infantile ailments.

During this critical period in the baby's life the diet must be extra light; starchy food should be reduced to a minimum and replaced by raw and cooked fruits and vegetables juices. Cooling sitz baths will help to keep the bowels active and to abate internal fever.

9. Acute Catarrhal Disease. Acute catarrhal diseases of infancy such as croup, cold in the head, acute bronchitis and whooping cough, are different forms of acute elimination through which Nature tries to purify the little body from hereditary and acquired accumulations of morbid matter, systemic poisons and disease taints.

In accordance with this conception of acute diseases, as purifying, healing efforts of Nature, we would not do anything to check or suppress elimination but cooperate with Nature in her purifying, healing efforts. How we do this has been fully explained in other parts of this volume. (Section VIII)

The natural treatment is very much the same in all acute inflammatory ailments. Feeding must be reduced to a minimum. If the baby does not insist upon eating, nothing should be given except water with acid or sub-acid fruit juices, such as lime, lemon, grape fruit and orange. If the temperature does not run high, say not above 100 or 102 deg, frequent ablutions with cold water at intervals of from one to two hours will be sufficient to promote heat radiation and elimination of morbid matter through the skin and other organs of elimination. If the temperature runs higher, say between 102 and 105 deg, wet packs must be applied, and renewed when they become hot or dry.

The wet packs are of especial value in all kinds of cough; whether it be the ordinary cough, croupy cough or whooping cough. A whole body or trunk pack, with or without a throat pack, will give almost instant relief. In many instances where baby is making the night hideous for the anxious mother, with it's coughing, a well-applied whole body pack, or a combination trunk and throat pack, will relieve the coughing almost instantly, and induce restful sleep.
In serious cases it is always advisable to call in a natural therapist or some other drugless physician, if one can be reached.

The mother should not forget that all acute diseases, after they have once developed, must run their natural course. She must, therefore, not become impatient and lose faith in the natural treatment if it takes a week or more to cure a common cold in the head or an attack of bronchitis, or if it takes from two to eight weeks to cure a case of whooping cough. Serenity, patience and cheerfulness are the primary requisites of the nature cure physician.

PART IV

BABY BOOK

Natural Therapeutics has undoubtedly solved the problem of treating human ailments. All other schools and systems will in time have to adopt the natural way. It is the hub of the healing art; all therapeutic methods radiate from it like spokes from a wheel.

Natural Therapeutics, however, has something better to give than treatment of disease, and that is prevention of disease. If children were brought into this world in the manner ordained by Nature and reared in harmony with the teachings of natural philosophy, disease would soon be a thing of the past. Human beings would then enjoy good health and be as beautiful and perfect in their kind as are animals, which live in the freedom of Nature, guided by instinct and therefore in harmony with the laws of their being.

We must begin, then, with prevention, for prevention is always easier and cheaper, than cure. But where must we begin to study the prevention of disease? Some will say, "At birth, because that is the beginning of life." Not so: that would be too late. The mould is made and the foundation laid for health or disease, for happiness or suffering, for efficiency or deficiency, before the human being in process of creation sees the light of day.

"Then," it may be said, "we must begin with prenatal influence, for the physical, mental, emotional and moral habits of the mother influence powerfully the development of the new life she is carrying." True—but we must start earlier than that. The making of the human being begins with mating and conception. All subsequent development depends upon the right start.

SECTION XXXII

Heredity

1. Importance of Correct Mating. Of primary importance in the sacred rite of procreation, as already intimated, is mating. This should take place only between descendants of the same subrace, or of closely related subraces such as the Indo-Caucasian and Celtic.

If the racial descent of the marriage partners is so far removed that it has produced pronounced differences in racial
characteristic—as in the case of the swarthy Mexican and white skinned Englishwoman, or the dark eyed Magyar and blue-eyed Scandinavian—then procreation becomes miscegenation and degenerates into mongrelization of the offspring. Everywhere in the animal and human kingdoms Nature has set the mark of disapproval on the mongrel. The offspring of miscegenation is doomed to deterioration and extinction unless assimilation of the elements of a lower race by a higher takes place sparingly and gradually.

The law of racial purity may be summed up as follows: When a member of a higher race cohabits with a descendant of a lower race, the offspring of the union loses more or less the characteristics of the higher race and reverts in physical, mental and moral traits to the level of the lower race.

The constructive results of racial purity are evident in Hindus of the higher castes; in that portion of the Jewish race which in mating has faithfully adhered to the Law of Moses, and in the blond and blue-eyed remnants of the Indo-Caucasian and Celtic races in Northern Europe and North America. The destructive results of miscegenation are plainly evident in the mongrelized population of Mexico and everywhere in the half-breed and many kinds of mixed breeds. These usually fall below the physical, mental and moral standards of the parent stock, and almost invariably revert to the customs and habits of the inferior race.

2. Use Heredity. Use heredity deals with the transmission to offspring of acquired physical, mental and moral characteristics of the parents. According to this law as it has been formulated, the chances of the offspring for long life, health, mental efficiency and moral stamina, other conditions being favorable, are better in direct ratio to the advancing age of the parents at the time of conception. While this is contrary to popular opinion, which assumes that younger parents produce more perfect offspring than older ones, the fact of use heredity is proved, both in the animal and human kingdom, by common observation and statistical evidence.

The working of the law is based on the fact that the procreative elements of the parents, or rather the microzyma of those elements, cannot contain the impress of physical, mental and psychical characteristics which at the time of procreation were not developed in the threefold organisms of father and mother.

The age of the father at conception is called the "birth age" of the offspring and determines its birth rank. While the father and previous male ancestors, for reasons hereafter explained, seem to exert greater control over the mental and physical characteristics, the mother furnishes the nutrient soil for physical growth. This does not mean that she exerts no control over the mental and psychical characteristics of the offspring; in addition to her influence through use heredity she has added opportunities through prenatal influence and postnatal training.
According to this law, then, the chances of the offspring for excellent physical, mental and moral development become better as the age of the father at the time of procreation advances beyond thirty five; while the physical condition of the mother for reproductive function is best below thirty five years.

But we must not overlook the fact that too great a discrepancy of age between the man and woman may become the cause of physical and mental incompatibility, of aversion and great unhappiness, especially on the part of the younger woman.

Extensive statistical evidence seems to prove that the birth age of the mother has been of less importance than that of the father. As will be shown in Natural Eugenics, the majority of famous men in all lines or human endeavor had old male ancestors, while the mothers and previous female ancestors were of much younger age at the time of conception.

This may be accounted for by the following reasons:

The man is usually considerably older than the woman at the time of marriage. Men, as a rule, devote much more time and effort to acquiring a scientific, professional or business education than do women. This has been true in the past more than it will be in the future. Thrown early into the competitive struggle of life men generally have had to make greater mental and physical effort than have women.

These points are of considerable importance because it has been proved that it is not inherited brain mass and mental capacity, but strenuous and persistent effort that intensifies use heredity. The earlier this begins and the longer it continues before procreation takes place, the better the chances of the offspring for physical, mental and moral capacity.

The reproductivity of the mother has usually ceased at thirty-five. Though she be capable of childbearing a few years longer, usually conception has been avoided after that age. Men under favorable conditions remain reproductive to advanced age. Some of the world's greatest men descended from fathers over sixty years old.

That intellectual and creative capacity has followed the male line of descent rather than the female line, is indicated by the fact that the high intellectual capacity of many eminent men has skipped their daughters to reappear in male descendants. This may be partly accounted for by the fact that the daughters in their limited spheres of activity have not had the opportunity to unfold inherent intellectual capacity to any conspicuous degree.

There has been a tendency in some quarters to criticize the general entrance of women into professional and commercial life and to dilate upon the adverse influence this will have
upon womanly characteristics and family life.

In the light of the knowledge we possess upon the subject of use heredity, it is safe to say that any such problematical drawbacks will be far outweighed by the general postponement of the marriage age. This will insure not only better physical fitness but also higher intellectual development and greater moral stamina on both sides of parentage.

The tremendous benefits which this increased hereditary endowment will confer upon future generations cannot be overestimated. Greater intellectual and economic equality between the sexes will emancipate woman from degrading sexual subservience. Under the old order, sex appeal was too often her only stock in trade by which to attract and hold the male and thus to secure a living. Economic independence will insure greater consideration and higher esteem for the woman on the part of the man. It will go a long ways toward solving the problem of birth control in a natural way, by leaving it more largely to the judgment of the mother.

We find the law of use heredity according to birth age verified in the intelligence and moral development or obliquity of races, nations and tribes all over the earth—The lower the average birth age of a race or nation, the lower, other things being equal, the intellectual and moral development The greatest development and efficiency is found among those nations where marriage is delayed to a later age through custom, economic necessity, professional or military training.

The following quotation from "Control of Heredity", by Casper Lavater Redfield, is of interest in this connection:

"In general it may be said that wherever there are no restraints upon the sexual propensities, as with the Digger Indians, the Fuegians, the Andamanese, the Wauraus of the Guianas, the Bushmen and the tribes along the Gabbon river, there we find reproduction taking place at the earliest possible age, and the lowest grade of intelligence. Where we find some special circumstances or customs that delay the age at which reproduction takes place, as with the Patagonians, the North American Indian and the Polynesians, there we find considerably higher grade of intelligence.

"Where we find the custom of marrying late in life, as was customary with the Greeks and the Romans, there we find a very high grade of intelligence. And where we find a fortuitous succession of very late births, there we find the very great men of the world's history.

"In other words, the longer the time in which the individuals have in which to use, develop and strengthen their brains before reproduction begins, the greater and more powerful are the brains of their descendants."

In Volume IV of this Series I shall quote elaborate and
highly interesting statistics from Redfield, which reveal the effects of the various birth ages on physical, mental and moral characteristics. I shall confine myself, for the present, to the statement that, with few exceptions, the great artists, scientists, philosophers, statesmen and philanthropists were born from fathers whose ages ranged from forty to sixty-five years at the time of the procreation of their famous offspring.

The existence of these laws and principles as facts in nature is very evident in the training of racehorses and of other animals along certain lines of proficiency.

3. Pernicious Heredity. The effects of deteriorating and destructive heredity prenatal and congenital influences have been traced and commented upon in so many different ways that I do not believe it necessary to enter deeply into this phase of the subject. Various authors have filled entire volumes with the unsavory family histories of the descendants of the Jutes, Ishmaels and other drunkards, prostitutes, degenerates and criminals, which prove positively the transmission of morbid and pernicious traits through successive generations. It has been proved statistically beyond the shadow of a doubt that youthful delinquency, pauperism and criminality are the aftermath of immature marriages.

The laws of use heredity and prenatal influence, like all other natural laws and principles, manifest along opposite lines of expression. It remains for us to determine whether we shall align ourselves with their destructive or constructive activities. The effects upon ourselves and our offspring will show accordingly.

If I succeed in arousing the consciousness of prospective fathers and mothers to the glorious privileges and enormous responsibilities which these laws of nature confer upon them, then my labor will not have been in vain and I shall feel deeply gratified.

SECTION XXXIII

1. The Creative Alchemy of Love and Affection

Procreation—as is the case with everything else pertaining to the constituents and functions of the human entity—takes place on three planes of being, the material (physical and spiritual), the mental and the psychical planes. Which of these elements shall predominate in the offspring depends upon the mixture and adjustment of qualities in the triune makeup of the mating couple. In order to fulfill the law and to draw the divine blessing upon themselves and the fruit of their union the partners in the procreative function must be united by the bonds of love, or at least by the ties of true affection.
The source of creative genius is love and wisdom, and the essence of intelligence and power is sincerity and goodness. Without these, intelligence degenerates into selfish cunning, power into self-destructive brute force. The spring cannot rise higher than its source; its water cannot be pure and wholesome when contaminated by impure admixtures from filthy surroundings.

It is not generally known that use heredity pertains to intellectual and psychical qualities, as well as to the physical material. Animalism breeds nothing but selfish animalism. The vampire who craves and absorbs the love of its victims and robs them of vital energy, without being capable of feeling or bestowing affection, is the child of a discordant union—of brute animalism on the part of the man, of secret aversion and hatred, usually, on the part of the woman. These bestial and degrading tendencies on the one side, and unrequited love craving on the other, breed sex perversion, and propagate the harpies who delight in the seductive power of superficial beauty, while gloating over the weakness and ruin of their victims.

True love and affection, paired with intelligence and goodness; liberate the creative elements necessary to the production of perfect offspring.

The finer qualities of mind and soul open the fountains of life on the higher planes, liberate and harmonize the male and female procreative fluids, and charge them with the purest and most potent intellectual, spiritual and psychical elements.

The divine fire of creative genius burns only in the love aura of truly mated couples. It is true that these are rare under our artificial, unrighteous social institutions, and that accounts for the rarity of complete manhood and womanhood.

Perfect offspring, endowed with beauty and power of body, mind and soul, destined to shed through life a radiance of health, happiness and helpfulness—to love and be loved—issues only from the union of love and affection with intelligence and goodness.

"Love lieth at the foundation" (of all that is). "Love is passion, enthusiasm, affection, heat, fire, soul—God."

To the extent that love enters into the holy rite, to that extent its attributes will be absorbed in the threefold organism of the woman and become active in the child building in her womb. While she loves her man more than ever, her most passionate affection is centered in the new being in process of development. On it she bestows the purest and best in her food and drink, in her thoughts, emotions and secret desires. Fear, worry, anxiety, jealousy and hatred are strangers to her soul; these are the emanations of the lower spheres—she lives in heaven.

Somebody endowed with deep insight into these matters has
said:

"Whatever male and female shall truly will for, hopefully pray for and earnestly yearn for, when love pure and holy is the nuptive ascendant, in form, passional, affectional, divine and volitional, that prayer shall be granted, and the boon be given—but the prayer must precede."

What are the direct effects of the marital rite upon the participants? If the sex attraction operates on the physical material plane only, if lust instead of love presides at the matrimonial feast, then temporary gratification of erotic craving will be followed inevitably by monotony, satiety, gradual revulsion and aversion, culminating in a morbid craving for change and variety. The partners in carnal self-indulgence are intuitively aware of these tendencies to marital unfaithfulness, and, therefore, easily dominated by distrust and jealousy.

The procreative function is attended by complete satisfaction, buoyancy of body and mind and lasting happiness only when sex attraction operates on the higher and highest planes of being, as well as on the lower, when desire and impulse are operative on both sides. Thus only will the generative function fulfill its sacred purpose and confer the highest possible benefits upon parents and offspring.

The woman, being the more highly sensitized, must be responsive to the call of holy passion. To force unwilling compliance will ruin the woman, kill her love and curse her offspring. Balzac says: "He who begins with his wife by a rape is a lost man." It is impossible for a wife to love unless she is won, not forced to compliance.

2. Sexual Intercourse During Pregnancy. Sexual intercourse should be considered the most sacred function of the human entity. From the highest and best viewpoint it should be exercised only for the propagation of offspring. However, considering the present stage of ethical and moral development, temperate indulgence may not be wholly condemned. Excessive intercourse is always weakening and harmful to both participants. We must remember that the sex fluid is the carrier of the life force. It is that which constitutes strength, resistance to disease, initiative and genius. During abstinence from intercourse the sex fluids with their creative energy are absorbed through the inguinal glands into the organism and increase physical, mental, moral and spiritual capacity and energy.

Set rules for frequency of intercourse cannot be given. This must depend entirely upon individual conditions. One safe rule is that after indulgence there should be no feeling of satiety, weakness and exhaustion. The more frequent the indulgence the stronger will grow the power of habit and of passion and the greater will become the abnormal craving. It is the same with all other appetite and passions. The more frequently they are indulged, the stronger they grow, until
they attain complete control and develop into destructive habit.

A free and confidential understanding in regard to these matters between those who contemplate matrimony would go far to prevent marital misery. A great deal of unhappiness arises from the fact that mates in the matrimonial union often labor under misapprehensions concerning the attitude of each toward the sex relation, and are prevented by excessive sensitiveness and delicacy from frankly discussing it. (For further discussion of this subject, see page 390, Volume I.)

There is no problem of married life that needs more thorough mutual consideration and understanding than this one. Lack of it accounts for a great deal of "incompatibility," loss of love, revulsion, hatred, and the final tragedy in the divorce court.

Among animals, no female allows intercourse after conception. In this respect as in many others, man has sunk below the natural standards of the animals. No greater crime can be committed against the woman and the unborn life.

It is a sad commentary on our system of education, scholastic as well as religious, that our young people are not instructed before and after marriage in these all important laws of Nature. To do this should be the province of the priest who unites them in marriage, or of the family physician, if the parents have failed in their duty.

It is well known (notwithstanding the denials of medical skeptics) that the unborn infant may be "marked" by transitory impressions, especially by strong emotions; that even insignificant parental characteristics are reproduced in the offspring. Is it any wonder, then, that the most powerful of human emotions should leave its impress on the growing brain and sex centers of the fetus, causing abnormal and precocious sex consciousness?

All too often is sex perversion born and bred in bone and flesh, before the child sees the light of day. The mother cannot be blamed for this "slaughter of the innocents"; she has not been instructed on the subject. Though she intuitively senses the horror of it, she submits, in order to maintain her hold upon the man—and many a life is thus cursed before it is born. The fault lies primarily with those of the medical profession who teach our young men that the free indulgence of sexual passion is not only legitimate, but a necessity to manly vigor.

This dictum of pseudo-science is almost universally concurred in by spiritual guardians. No greater lie was ever promulgated from the blackest abyss of Hades. If our young men were taught that greater happiness is to be attained by the exchange of tender affection than by the indulgence of the coarser animal appetites, that the creative forces thus preserved develop and strengthen their own finest capacities
of body, mind or soul, they would wisely and chivalrously protect mother and child, at the same time conserving their own physical and moral integrity.

In no other way is it possible to call forth the deepest gratitude and unfailing esteem of a true woman. Many a man whom we have thus advised has become a lifelong friend in consequence.

3. Limitation of Offspring. I believe that the unlimited production of offspring, encouraged in some quarters for swelling the ranks of religious bodies or for increasing tax paying and cannon-fodder material, is a misfortune, both to the family and to society. Limitation of offspring, in accordance with the means and circumstances of the parents, is not only justified but should be encouraged. In any case, the production of offspring entails great responsibility upon the parents and if they cannot properly comply with the needs and rights of their children, they fail in their responsibility and duty.

Any method, however, which interrupts intercourse or prevents conception in an artificial way, is absolutely to be condemned, because this has very harmful and positively destructive effects upon the physical, nervous and mental organism of those who thus try to cheat nature by the suppression of a natural process. In our professional work we frequently meet the victims of such pernicious practices. The ordinary contrivances for prevention make of intercourse something akin to masturbation. This is also true of intercourse without orgasm which is strongly advocated under various guises. The use of poisonous antiseptics and germ killers in warm water douches is not essential for prevention, and is highly injurious. These chemicals have a tendency to poison the sexual organs and to produce in time atrophy, many kinds of female disorders, and tumors. Undoubtedly the greater number of so called female troubles and malignant tumors in later life are caused by curetments, antiseptic douches and the use of poisonous drugs, for producing abortion. The only legitimate methods of birth control are abstinence or common cleanliness.

There is nothing more conducive to the physical, mental and spiritual health and development of a woman than childbearing and child rearing in harmony with Nature's laws, as outlined in these volumes. Under favorable conditions it is not a thing to be dreaded, but to be looked upon as the greatest of blessings and opportunities in the life of a woman. Natural philosophy and practice takes these problems of progeneration, childbearing and childrearing out of the domain of uncertainty and haphazard management with its dire consequences, and makes eugenics the most exact of all sciences and the sublimest and most enjoyable of all the arts.

4. Determination of Sex. Numerous theories have been advanced concerning this interesting subject. Many attempts have been made to wrest from Nature the secret of sex
determination and numerous more or less ingenious methods have been recommended for sex control.

I know of one method only which seems to have a rational basis and which has proved of practical value. Observations seem to prove that the right ovary liberates male ova only, while the left ovary discharges female ova. The two ovaries discharge ova only at alternate menstruations.

With this data at hand, it is possible to determine the sex of a child after one birth has taken place. Suppose the first child was a boy. By consulting our pregnancy table (page 377) we can determine when the last menstrual discharge took place. This menstruation liberated a male ovum; the next menstruation would liberate a female ovum, the next a male, etc.

Thus, using the last menstruation period before the last conception as a fixed point, it would be possible, figuring from period to period, to determine the sex nature of the ovum to be discharged at each following menstrual period. Account is taken of all regular periods during the time menstruation is suspended in pregnancy. Thus, conception may be timed in such a way as to impregnate at will a male or female ovum.

This solves in a simple, rational manner another of Nature's riddles, namely, the reason for the practically equal division of the sexes.

SECTION XXXIV

Prenatal Influence

There exists just as much diversity of opinion among scientists concerning the reality of prenatal influence as about race heredity, use heredity, disease heredity and many other mooted problems of science and philosophy, which we shall study in Vol. IV of this series. In the following I shall present and examine impartially the various theories and opinions concerning prenatal influence; then we shall be better prepared to draw our own conclusions.

1. Medical Science Denies Prenatal Influence. Medical men, as usual cocksure of the correctness of their theories and hypotheses based on the "latest discoveries", deny and ridicule the possibility of prenatal influence, and relegate it to the rubbish heap of popular superstitions. They base their judgment on the fact that no nerves pass from the body of the mother through the umbilical cord into the growing fetus in the placenta, which forms the soft protecting nest of the new life within the womb. They claim that since no direct nerve connection exists between the two, mental and emotional vibrations cannot be transmitted from the brain of the mother to the brain and nervous organism of the fetus.
Are there no other means of communication between the mind of the mother and the brain of the unborn!

In the volume dealing with Eugenics we shall learn how universal intelligence and creative will become individual intelligence and personal will.

Cosmic vibrations do not flow into the gray matter of the human brain over coarse physical nerve tracts. They come over the psychical wireless which connects the human soul with the world Soul, the individual intelligence with the universal or cosmic intelligence the human will with the divine will.

Since, as proved by modern brain and nerve anatomy, immaterial cosmic intelligence and "power to will" fashion the brain of the mother into physical material centers for the expression of human intellectual faculties, capacities and powers, why cannot these cosmic vibrations act in like manner over the psychic wireless through the soul and mind of the mother on the brain and nervous system of the fetal organism?*

These epoch making discoveries and revelations of modern brain anatomy are explained in Vol. IV of this Series, *Natural Eugenics—Man Building on the Physical, Mental and Moral Planes.*

Why should the wireless, which transmits impulses of intuitive intelligence from the great source of all intelligence and creative energy into the soul of the mother, cease to operate at that point, and fail to transmit its message to the brain and nervous system of the fetus which is most intimately related and connected with the organism of the mother?

What about the phenomena of hypnotism? Absolute control of the subject's mind, through the intelligence and will of the hypnotist does not depend upon the existence of an umbilical cord and physical nerve connection between the two. The hypnotist, by silent command, may call his subject from a distance, far beyond the reach of his voice.

People telepathically attuned may communicate in like manner, spontaneously, or by conscious intent. Why then should we doubt the possibility of vibratory correspondence between the mental and emotional conditions of the mother and the plastic nervous organism in process of development within her womb?

If a complexity of sound can impress itself permanently upon the wax cylinder of a phonograph, or what is still more marvelous, if the photographic rays of passing scenes can be fixed and retained in the picture film, why should it be impossible for the mental and emotional vibrations of the mother to impress and modulate the molecular and cellular constituents of the fetal brain and nervous organism?
I have compared this creative power of the mother mind to
the process of electrotyping. As the particles of metal in
suspension in the fluid adhere to the spoon that is to be coated
with silver, so the atoms and molecules in the gray matter of
the brain of the fetus group themselves in harmony with the
thought forms and emotional vibrations of the mind and soul
of the mother. While this mental and psychical electrotyping
takes place automatically, the mother's brain and nerve
molding power can be greatly strengthened and intensified by
the \textit{conscious} and \textit{voluntary} operation of the psychical
wireless that establishes vibratory oneness between her and
the human entity in process of development within her own
body.

Thus it is revealed how a brain prenatally refined, organized
and fashioned may endow the nascent individuality with
certain aptitudes and talents along established paths of
cerebration. There surely will be less resistance along such
lines of physical, mental and moral endeavor than along other
lines not prenatally influenced and molded. Therefore I
strongly advise mothers, pregnant with new life holding
marvelous possibilities for good or evil, not to be influenced
by the superficial reasoning of materialistic science, but to
follow the sacred intuition and impulse of their own creative
genius in this, the most holy function of their being. Every
normally constituted mother is intuitively aware of this
wonderful power, and is willing and anxious to exercise it
when her consciousness has been aroused to the great
possibilities and responsibilities which the divine privilege of
motherhood confers upon her.

It is natural for us to admire a great artist who portrays the
human form, true to life, on the painted canvas, or who
fashions it from inanimate stone, metal or marble; how much
more grand and godlike is the creative power of truly mated
parents whose privilege it is to bring into the world, and to
fashion according to their highest ideals, a human being
endowed with life and intelligence, with the infinite
possibilities of a \textit{new center of creative activity}.

Yet many mothers, totally ignorant of their divine creative
privileges and possibilities, victims of physically and morally
degrading marriage relations, and often filled with secret
aversion or open hatred for their marital companions, pass
unwillingly through pregnancy and not infrequently seek to
destroy the new life. When the unfortunate victim of such
marital incompatibility, conceived in passion and developing
under the worst possible influences of mental and emotional
discord, comes to arouse the maternal instincts of affection
and devotion, then fear, anxiety and worry, like a continual
nightmare, haunt the unhappy mind of the mother and impress
their discordant vibrations upon the sensitive films of infant
consciousness.

Compare this condition of fear, apprehension and gloom in
the mind and soul of an unhappy and unwilling mother, with
the joyful and ecstatic state of mind of a mother conscious of
the creative power of her intelligent will, who, from the time of mating and procreation, with accurate prescience prepares the most favorable conditions, astrologically, prenatally and postnatally for the finest development of the physical, mental and moral characteristics of the future world citizen.

The loftiest exaltation of a creative genius working in dead clay and cold marble cannot approach the ecstasy of a mother who has acquired a knowledge of the great laws which make possible the development of a perfect human being, the embryo of a master, an angel, a being destined to be godlike in its faculties, capacities and powers!

In place of fear and anguish of soul, what joy to the mother who knows that it lies within her power to prevent disease and degeneracy in her offspring; that the development of the child depends solely upon her own intelligent effort! Nothing is left to accident. Child bearing becomes an exact science, the most beautiful and inspiring of all arts and professions. Under such conditions motherhood, instead of being the greatest of hazards and hardships, becomes a divine privilege and the highest achievement of human existence and endeavor. It falls short only of the creative work of the great Universal Intelligence whose instrument of creation is the mother.

2. An Example from History. Let us consider the oft-quoted example of Napoleon Bonaparte. His mother, Lutitia Bonaparte, while pregnant with the future military genius, accompanied her husband on a military expedition, sharing with him the hardships and excitement of camp life, and the marches and battles of a military campaign. If there be nothing in prenatal influence, is it not singular that Napoleon should have become one of the greatest military geniuses of all ages, while not one of his many brothers ever exhibited enough military ability to make an efficient corporal? What was it that favored or determined the birth of the great military prodigy under these circumstances? The ancestors of Napoleon's father were not professional soldiers, nor was the father especially interested in military matters before the conception of his gifted offspring.

The dominant influences, therefore, must have operated through the singular occupation and surroundings of the mother during this particular pregnancy.

Many similar striking examples have been cited in works on prenatal influence. I myself might add many convincing proofs from an extensive experience in medical practice; but time and space do not permit. Contributory evidence may be secured from many excellent works dealing with this vital problem in human life. I may be permitted to say that use heredity and prenatal influence are distinctly manifest in the physical and mental characteristics of our three children who were born at intervals of seven and five years. Each one of them clearly mirrors in his or her physical, mental and emotional peculiarities the predominant mental tendencies, occupation and surroundings of the parents during the
respective prenatal periods. Similar manifestations of prenatal influence may be observed in almost any family.

3. Birthmarks. Medical men of late deny also the possibility of "marking" the offspring by sudden fear or shock on the part of the mother during pregnancy. Incidents of this kind, however, are of such common occurrence that it is a waste of time to refute these flippant denials.

There are good reasons for believing that such marking is more likely to occur during the periods when the menstrual flow should take place, but is suspended.

It may be argued that to mention the possibility of marking to a pregnant woman will greatly increase the probability of electrotyping violent emotions upon her offspring; in other words, that the fear of the thing will help to materialize it. This may be true to a certain extent, but we must remember that sudden shock through fear or disgust may cause the mischief anyway, whether or not the expectant mother is aware of the possibility. Understanding a danger and being prepared for it seems the best protection. The pregnant woman should study carefully section XXX, dealing with mental and emotional causes of nervous diseases, and should learn to relax to any sudden surprise and thus neutralize unpleasant and fear arousing impressions. Self-control is the royal remedy and the key to mastership.

4. Physical Influence. Now that we have studied some of the more important hereditary mental and psychical prenatal and postnatal influences, let us see how the physical condition of the mother's organism influences the brain and nerve matter of the fetus in its last stages of development, and after birth.

Materialistic science teaches that brain matter exudes thoughts and feelings, as the liver excretes bile, or the stomach pepsin. Natural science proves that mind is superior to matter, that the new born ego, by the power of intelligent volition, must fashion in the gray matter of the brain the molecular groupings or centers for the expression of intellectual and emotional activities, such as language, music, numbers, scientific and philosophic speculation.

This means that active cerebration and brain molding do not begin until after birth. But it stands to reason that the work of the nascent intelligence may be greatly facilitated or impeded by the physical condition of the brain. It is reasonable to assume that intellectual and emotional vibrations will more easily shape the gray matter of the brain into new configurations when it has been prenatally refined, organized and developed along certain lines of cerebration by use heredity and by constructive prenatal influences.

There exists a remarkable similarity between the brain molding and memory building activities of the intelligent ego and the making of phonographic records and moving picture
films. Lifelike impressions of sounds and passing scenes can be made upon the phonographic and photographic mediums only when wax and film are in a highly refined and plastic condition. When impure of substance and coarse of texture they, are not sensitive and plastic enough to register and retain the subtle and highly complex vibrations of sounds and passing scenes. In order to receive and register a great variety and complexity of sounds, the wax on the phonograph cylinder must possess a certain degree of refinement, softness and plasticity. If it is too hard and coarse it registers the loud and coarse sounds only. Such a record cylinder, exposed to a beautiful symphony executed by a great orchestra, would register and reproduce only the shrill cries of the trumpet, the rattle of the snare drum and the booming of the big horns and bass drums. The softer sounds of string, wood and wind instruments and finer shadings of tone and rhythm would be lost. With increasing refinement and plasticity, more subtle and delicate sound vibrations will be retained and reproduced.

In like manner the sensitive gray matter of the cortex of the brain must be in a pure and plastic condition in order to receive and register the impressions and impulses coming through the sensory organs, the psychic intuition and the intellectual and emotional activities of the mind. Anything in the way of physical impurity or foreign matter that tends to clog the brain, or to feed it with waste and morbid materials, or with corroding poisons, will lessen the atomic and molecular motility of brain and nerve matter, and will interfere with, or impede, the groupings and subtle transformations involved in the fashioning of brain centers through mental and emotional influences.

If the nutrient blood which feeds the brain substance of the fetus be saturated with CO₂, the benumbing, paralyzing carbon-dioxide, with clogging uric acid or the destructive acids of phosphorus and sulfur, the gray matter cannot, respond to the subtle and complex impressions and impulses from without and within.

The purity or impurity of the plastic matrix of the cortex depends upon the materials absorbed from food and drink. If these are so constituted as to create in the system excessive amounts of clogging and corroding substances, then these food and drink poisons will have a benumbing and deteriorating effect upon the sensitive gray matter of the brain, as well as upon the coarser tissues in the joints, muscles and vital organs. There is a rheumatism of the mind as well as of the joints.

A brain asphyxiated and clogged with pathogenic materials cannot be alert and active; it is too dull and lazy to think; it would much rather sleep than work; it is incapable of doing its best when its tiny blood and lymph vessels are obstructed with waste and morbid deposits which prevent the oxygenation and drainage of its delicately organized cellular tissues.
This, of course, is true postnatally as well as prenatally. A brain originally capable of the highest and finest achievements of the human mind may become utterly worthless, and may degenerate into idiocy through food, drink and drug poisoning.

Medical men tell mothers they need not worry over prenatal feeding, because the placenta, the vascular bag which forms the nest of the new life, acts as a filter which purifies the blood before it reaches the fetus. Common sense and every day experience tell another story. Even the best in the blood of many mothers is bad enough to serve as food for the new life.

The placenta does not filter out of the blood of the mother all food, disease and drug poisons. This is proved by the wretched condition of many infants, suffering from malnutrition, anemia and rachitis, after delivery. If the vital fluids of the mother are deficient in the mineral elements, or in other important nutritive substances, how can they deliver them to the fetus?

Occurrences like the following, quite common in our institutional practice, prove positively that the placenta is not a perfect filter for systemic poisons and for disease taints circulating in the blood of the mother.

One of the most pitiable cases of eczema in a little child less than one year old we traced to the fact that the mother, during her first year of marriage, had traveled with her husband through Eastern European and Asiatic countries, and during her pregnancy had been vaccinated five times while passing through localities where smallpox was prevalent. Both she and her husband had always enjoyed perfect health. The family record was excellent as far as traceable; still the body of the infant soon after birth, was covered with open bleeding sores, presenting a revolting sight. We could find no explanation for this strange phenomenon other than the many vaccinations during pregnancy. These had contaminated the blood of the mother, and through her the body of the fetus, with a filthy scrofulous taint.

The baby suffered terribly. For many months it slept but little, because of the excruciating pains. The eczematous eruptions were of a very stubborn nature; they broke forth again and again. Finally, however, after eighteen months of natural treatment, we succeeded in purifying the little body of the horrible infection. The child is now a little over three years old, in perfect health, and during the last twelve months has shown no signs of the morbid taint.

Under another section I shall describe the influence of food upon character and sex life.

To recapitulate: Purity, plasticity and motility of the highly refined and sensitive materials which make up the gray matter of the brain depend upon pure food, plenty of fresh air and exercise, and upon all other natural methods of living
SECTION XXXV

Conception and Pregnancy

1. Conception takes place whenever the male spermatozoon joins the female ovum (egg) within the woman's womb. Normally the female organism liberates from its ovaries but one ovum each month, usually during menstruation, while the male discharges millions of spermatozoa at each orgasm.

Conception does not always follow copulation. The ovum remains in the womb and is capable of impregnation for about five days after menstruation. The spermatozoon on entering the womb may meet an ovum which has been discharged at a previous menstruation, or it may remain alive in the womb for a number of days and finally come in contact with a newly discharged ovum at the following menstruation.

The spermatozoon retains its ability to impregnate the ovum for from ten to fifteen days after its discharge into the womb. When the male and female germs merge into one another, conception or impregnation takes place. As soon as this has happened, the impregnated ovum becomes attached to the inner lining or mucous membrane of the womb and begins its new life as an embryo. The period comprising the time from the impregnation of the ovum until the beginning of labor or childbirth is called pregnancy.

The table of pregnancy on page 377 indicates the probable date of normal termination of a pregnancy, calculated from the last menstruation.

2. Exercise During Pregnancy. Unfortunately a great many expectant mothers labor under the idea that they must rest and be relieved from work and exercise. This of course is a great mistake. Light housework is good exercise. There is nothing more harmful during pregnancy than nursing "that tired feeling" by lounging idly about the house and coddling one's real or imaginary aches and troubles.

Of great benefit to the pregnant woman are all outdoor sports such as tennis, golf and other games which require vigorous exercise without straining or overworking the body. The great benefit of walking and other outdoor exercises, aside from their general invigorating effects, lies in the strengthening of the abdominal muscles and ligaments, which at delivery will greatly facilitate expulsion of the fetus.

The walk should be brisk and rhythmical, body erect, head thrown back, chest forward; the breathing at the same time should be deep and regular. These walks should be continued as long as time and endurance permit. Nothing, of course,
must be pushed to the point of exhaustion. One good long walk every day is necessary; two are better.

We all understand the necessity for a plentiful supply of oxygen under ordinary conditions, and especially in time of illness. During pregnancy the demand for oxygen, as well as for mineral salts, is doubled or trebled on account of the needs of the rapidly developing organism in the womb of the mother.

These extra demands for oxygen and ozone must be supplied by systematic deep breathing, cold bathing, outdoor walks, etc. If circumstances do not permit the taking of outdoor exercise, deep breathing should be practiced as often as feasible, at the open window.

Next in importance among gymnastic exercises is the internal massage described under section XXI, No.16.

Those exercises are especially valuable which bring into play the abdominal muscles and the muscles and ligaments of the genital organs.

3. Clothing. Clothing and the manner of wearing it profoundly influences the normal or abnormal development of the fetus, the health of the mother, labor and delivery.

At no time should the waistline be constricted by a corset or even by the ordinary skirt band. All clothing should be as loose and light as possible—one-piece under and outer garments, with the weight suspended from the shoulders, are best. If skirts are worn they should be fastened to skeleton waists of some thin cotton material. The close, heavy texture of the material from which the corset or so called "reform waist" is made is injurious because it interferes with skin elimination.

Even the slightest constriction of the waist line interferes with the free circulation and the normal blood supply to the abdominal organs, which is of especial importance in pregnancy; it also hinders the free expansion and movement of the uterus during the various stages of pregnancy.

Within the waistline are located a dozen or more important vital organs of the body. Any sort of constriction compresses these organs and pushes them out of their normal position. While this is extremely injurious to the body of a woman under ordinary conditions, it is doubly so to the pregnant mother and to the rapidly growing fetus. Undoubtedly many deformities and monstrosities are produced by unnatural constriction of the blood vessels and vital organs in the abdomen and pelvis of the pregnant woman.

If due attention is paid to the foregoing influences, labor and delivery will be brief and easy. This we have proved in hundreds of cases which have come under our management. The reason why women of civilized countries spend many
hours and sometimes days in dreadful agony of childbirth while those of primitive or savage races, as we call them, produce their young easily and painlessly as the animals do, is that primitive women live more simple and natural lives, while "civilized" mothers violate practically every law of Nature in their daily habits of living.

Civilization unfortunately stands in many respects for that which is artificial, unnatural and therefore productive of disease and suffering in all domains of life, not only as regards physical health, but social and political health as well.

SECTION XXXVI

Danger Signs During Pregnancy

1. Dropsical Swelling. Swelling of the limbs and distention of the veins of the legs during pregnancy may be caused by a tendency towards varicosity, intensified by obstruction of the circulation due to the enlarged uterus. Such a condition requires, aside from the natural regimen, careful and competent treatment.

Swelling of the limbs or other parts of the body may also be caused by incipient or advanced Bright's disease. The urine should be examined from time to time, especially if there is a swelling of the feet and ankles, or if there are dropsical symptoms in other parts of the body.

Such dangerous conditions are usually brought about through the excessive intake of starchy and protein foods which overwork the liver and kidneys and cause pathogenic dogging of the capillary circulation. This may result in uremia attended by violent and sometimes fatal Convulsions.

2. Uremia is the result of retention in the system of waste materials and poisons that should be eliminated through the kidneys and skin. Medical treatment for such conditions, aside from the administration of stimulating drags, consists in hot bathing with the idea of opening the pores of the skin.

We understand that all hot water treatment gives only temporary relief and is followed by greater enervation and inactivity of the skin. The best water treatment for systemic poisoning of any kind consists in the application of wet packs followed by cold ablutions as described in section XV.

The addition to the packs, dry friction rubs, air bath, good massage and neurotherapy treatment will aid in restoring the normal activity of skin, bowels and kidneys.

Whenever the urine contains sugar or albumen, fasting, alternating with raw food diet, is indicated. Suitable regimens are outlined in sections X, XI.
The giving of heavy food to the mother with the idea of increasing the flow of milk is all-wrong. We have found in all cases that the diet outlined in section X will produce a more copious flow of rich milk than lie "nourishing" meat diet. The best remedy for a scanty flow of milk is slow and thorough mastication of a few spoonfuls of raw crushed wheat every day.

3. Morning Sickness. One of the common disorders experienced during pregnancy is that known as Morning Sickness. One suffering from this ailment, though following a natural diet, should sip a cup of hot postum while remaining in bed. If this does not have the desired effect and if the patient has not been accustomed to drinking coffee, half a cup of black coffee with a few drops of lemon juice will quiet the irritated nerves. It is necessary after taking the hot drink to remain in bed for at least thirty minutes. It is understood that this is only an emergency measure. If continued, it will lose its good effect and work injury.

SECTION XXXVII

Labor and Delivery

At about forty weeks, exactly nine solar months, from the period of conception the fetus reaches full maturity, and labor begins. Labor is divided into three stages. During the first stage the neck of the womb becomes slowly and gradually distended and the orifice of the womb opens widely. When this has taken place, the fetal membranes burst and the amniotic liquid surrounding the fetus escapes.

During the second stage the fetus emerges from the womb.

After expulsion of the fetus, the placenta is expelled from the uterine cavity. This constitutes the third stage of labor.

The first stage usually begins with more or less radiating pains in the abdomen, accompanied by dull pain in the small of the back and a drawing pain in the limbs. Sometimes women with the first baby feel these pains weeks in advance of the actual commencement of labor. At first they occur at long intervals and are of short duration, but gradually become more prolonged and more frequent. The pains are due to a cramp-like contraction of the muscular apparatus of the uterus forcing its contents downward.

Under this pressure from above, the neck and mouth of the uterus distend to their limits, and the walls become thinner and thinner. First the inner, then the outer orifice of the neck of the womb opens and the fetal membranes protrude and finally rupture, allowing the amniotic fluid to escape. Shortly after this the part of the fetus nearest the orifice, normally the
head, makes its appearance. At the present time the average duration of the first stage of labor is six hours, but it may last twenty-four hours or longer, depending upon the plasticity and elasticity of the bony structures of mother and infant, the rigidity of the cervix, and the vigor or lack of vigor of the muscular apparatus of the uterus.

While the foregoing is true of the average delivery under ordinary ways of living, we find that after the enforcement of a natural regimen of living during and, better still, before pregnancy, the entire period of labor and delivery does not cover more than half an hour, or at the utmost from one to two hours. Even the disadvantages of slight build and smallness of pelvis can be overcome by the natural regimen outlined in section X. When our youngest child was born, the mother gave the first sign of pain at about midnight. I rose from bed instantly, but had not time to finish clothing when the membranes broke. Within twenty minutes after the commencement of labor the infant was resting in my hands.

The wife of a prominent lawyer in a western city had experienced three difficult deliveries. Each time surgical instruments had to be used and she had suffered untold agonies lasting from 24 to 36 hours. When she became pregnant the fourth time the most prominent physicians in her home city assured husband and wife that it was not safe for her to go through another delivery, that the womb was in worse condition than ever before therefore they recommended surgical removal. For conscientious reasons, however, the husband and wife did not follow the advice of the doctors, but decided to try natural methods of treatment.

The lady placed herself under our care during the fifth month of pregnancy. From that time on she followed strictly the natural regimen of living and received daily the usual hydropathic and manipulative treatments. This was continued until a few weeks before delivery. In this case the baby was born within an hour from the first contraction, and the mother of the patient, who was in an adjoining room, had not heard a sound. Many similar experiences refute the idea that it is unsafe and injurious for pregnant women to undergo the ordinary methods of natural treatment, such as hydropathic sprays, sitz baths, massage, Swedish movement and other forms of manipulation.

1. Preparation for Delivery. The diet during the last week before the beginning of labor should be very light, consisting mostly of fruits and vegetables. From the commencement of labor no food at all should be given, until at least twenty-four hours after delivery; a three-day fast is better.

In addition to a competent physician, a nurse or midwife should be engaged. If a good neurotherapist, who has had sufficient experience in obstetrical work, can be procured, he should be preferred, because he can assist delivery and make it much easier by manipulative treatment.
The nurse will make the necessary preparations and provide the various supplies needed in labor. With the first sign of approaching labor, the physician in charge should be summoned. A rectal enema of one pint or more of warm salt water (See. XVIII, No.4) should be administered. The woman should be given a vigorous cold rub and her genitals thoroughly cleansed. She may then remain on her feet and walk about, comfortably dressed, until actual labor commences.

2. No Anesthetics. The attending physician should not be impatient to hasten delivery with drugs or instruments. The use of anesthetics should be avoided insofar as this is possible. They should be employed only when absolutely necessary—that is, when excessive pain must be allayed or when surgical delivery is unavoidable.

3. Breaking of Water Bag. When the bag of water is about ready to break, the patient is placed in bed. Premature discharge of the amniotic fluid must be guarded against. An escape of the liquid at an early stage means difficult and prolonged labor, commonly known as "dry labor". Usually the membranes burst when the orifice is fully dilated. A large sponge is held in readiness to catch the out-flowing liquid.

3 a. Umbilical Cord. When the infant has been delivered, the umbilical cord should not be severed at once. Plenty of time should be allowed for the blood to transfuse itself from the body of the mother to that of the child. This is important. If the connection is severed too soon, the child begins life in an anemic condition.

The newborn baby usually greets the world with a lusty cry. It should be placed on its right side with its face turned away from the mother, care being taken that the cord is not stretched tight. As soon as the cord stops pulsating, plenty of time being allowed for blood transfusion, it is tied about two inches away from the baby's abdomen and cut a little above the ligature. The baby is now wrapped in a warm blanket and put in its crib.

4. After Delivery. Immediately after the baby is born, the nurse or attending physician gently compresses the abdomen and womb of the mother, kneading and rubbing it occasionally in order to secure complete contraction and thus prevent hemorrhage. After delivery the mother enjoys a period of rest and recuperation which usually lasts for about half an hour.

5. Afterbirth. Meanwhile the placenta becomes detached, and when the pains set in again a few contractions usually suffice to expel it with all the membranes.

The attending physician must make sure that none of it is left in the body, since this might result in putrefaction of the remains and blood poisoning. The woman's genitals should be washed with clean sterilized water.
The exhausted woman should now enjoy a deep, wholesome sleep and awaken from it in a few hours refreshed and strengthened.

In the foregoing I have not gone into the details of obstetrics and of technical management because this must be left to a competent obstetrician. I have called attention only to those points which are of special importance from the viewpoint of Natural Therapeutics and to the differences in treatment between the conventional and natural methods.

6. The Lying-In Period. The lying-in period varies from five to twelve days, according to the constitution of the mother and the care that she has taken during pregnancy. The greatest danger of the lying-in period is puerperal sepsis or blood poisoning. This condition is the result of infection occurring during labor, or it may result from the retention of parts of the placenta.

The only way to prevent this is by observing the most scrupulous cleanliness during the entire process of childbirth and during the lying-in period. When blood poisoning has developed it must be treated the same as all other acute inflammatory diseases (see section IX).

7. Care of the Newborn. The child should begin to breathe immediately after the cord is cut. If it fails to do this, the physician should lift the baby by its feet to facilitate the escape of mucous from the trachea and throat. If necessary the mucous must be removed from the throat by the insertion of the little finger, or by means of a tiny stick covered with gauze.

Breathing may be accelerated effectively by a few sharp taps on shoulders and buttocks. If this fails to bring the desired result, artificial respiration must be resorted to at once. The attendant grasps the child by its shoulders, its head resting between his palms and the two index fingers being hooked under the child's armpits. It is now swung between the physician's legs and lifted high above his head so as to be turned upside down. This is repeated from fifteen to twenty times, after which it is placed in a basin containing a few inches of warm water. Its body should then be rubbed briskly with cold water.

Father Kneipp used to take the newborn babe by the nape of the neck and the feet and submerge it quickly in cold water. This, a few times repeated, is probably the quickest way of resuscitating an asphyxiated baby.

In order to soften the cheesy deposit which frequently covers the body of the newborn, it is well to rub the skin with warm olive oil. After the greasy covering has sufficiently softened it may be removed with bits of gauze. This is followed by a cleansing bath with warm water and castile soap.
After the warm cleansing bath, the little body should be quickly rubbed down with cold water, wrapped in a soft, warm blanket and laid away to sleep until it wakens of its own accord. A normal baby should sleep for about twelve hours, and must not be disturbed to force food on it before it is ready to take it.

8. Bathing. From the first day, the baby must have a morning and evening bath. This consists, as before described, in a quick, cleansing bath of warm water and castile soap, followed immediately by a brisk cold rub. In the course of a few weeks the baby can be placed, for the cleansing bath, in a small bathtub containing a few inches of warm water. Immediately after the cleansing bath the warm water is replaced by cold water. This is taken up in the hollow of the hand and briskly applied to the little body. In this fashion the child, within a few months time, will enjoy its cold rub just as much as an adult. I have seen several such nature cure babies, but a few months old, object most vigorously to a warm bath. The cold rub is the best preventive of chilling; but care must be taken that the temperature of the room where the bath is given is not below 70 deg.

The olive oil bath or rub, often recommended for premature babies or infants suffering from malnutrition, is very injurious, because it occludes the pores of the skin and prevents the elimination of poisonous gases and other morbid materials from the body. The skin is not an organ of digestion. Olive oil, like all other foods, must enter the body through the alimentary canal where, under the action of digestive ferments, it is broken down into its component elements which are then assimilated through the intestinal membranes. Oil absorbed through the skin is not digested, and it circulates in the body as foreign matter which in this state cannot be assimilated and utilized in the system.

9. Powdering after the bath is fully as injurious as the rubbing with oils or massage creams. Powders and creams tend to clog the pores, and most of them contain poisonous antiseptics which lower the vitality of the skin and prevent or suppress elimination in the form of skin eruptions, eczemas, etc. For chafing use nothing but cold water. In case the chafing should become unusually severe and painful, through neglect by the caretaker, a soothing and healing lotion composed of one part lemon juice to two parts olive oil, may be applied a few times, until the irritation is under control.

10. Air Baths. Next to cold water, there is nothing that will invigorate baby's skin and nervous system as will the air and sun bath. If the season will not allow the outdoor air bath, the baby should be allowed to lie nude several times a day, for thirty minutes or more, in a warm, well ventilated and sunny room.

11. Constipation. Glycerin and suppositories should never be used; neither laxatives nor cathartics. Oat extract and cooling sitz baths will produce natural movements.
12. **Diarrhea** is a form of morbid elimination, and must never be suppressed by drugs. If it is habitual, bailey or wheat extract prepared in the same manner as oat extract, is a good remedy. If the diarrhea is persistent and of a violent nature, no food at all must be given, except water with dilute acid fruit juices, until the purging ceases. Even then plenty of time must be allowed for the rebuilding of the sloughed intestinal membranes.

13. **Bandages.** Until the umbilical cord dries up and falls off, it is necessary to cover the navel with a gauze compress dipped in olive oil. This is held in place by an abdominal bandage made of soft cotton material. These strips should not be hemmed, merely torn or cut. They should be drawn just snugly enough to hold the compress in place, but not tightly enough to interfere with circulation. The, navel must be cleansed and the compress renewed twice each day. After the umbilical cord has dropped off we no longer apply the abdominal bandage. This is contrary to common usage, but is the best practice. The abdominal bandage overheats the body and interferes with the free movement of the diaphragm and the circulation of the blood.

14. **Clothing.** The clothing of the infant should be loose and light and as simple as possible. Freedom of movement is very important; binding or pressure upon any part cannot help but interfere with the circulation, and otherwise produce injurious results. The clothes should be short, in order to allow the feet and legs free play. Light weight, porous cotton materials are best for both under and outer garments. A lightweight wool petticoat may be worn when absolutely necessary to provide sufficient protection for the baby. Cotton hose and bootees may be used, but under no circumstances should such articles be of wool, because it prevents free elimination from the skin. The baby's head should not be covered out of doors, except in severe weather. At no time should a veil be placed over the face, as it will cause the infant to reabsorb the poisonous exhalations from its own lungs. All clothing should be changed each day. No garment should be starched—such a practice is not only useless but harmful.

15. **Diapers** must be provided in sufficient number to allow thorough cleansing and drying. The wet diapers should be scalded in hot water and very thoroughly rinsed in several waters afterwards. They should then be dried in the open air and sunshine. Soiled diapers must be well washed and boiled. Washing powders, soda, ammonia and other chemicals should never be used. They have an extremely irritating effect upon the delicate skin of a baby. In order to save labor and to facilitate the cleansing of the diapers, small squares of clean old linen or muslin rags, or pieces of absorbent gauze, may be placed inside. These inserts will absorb all or most of the bowel movement and may then be burned. If the skin is irritated or chafed, the parts should be sponged off with clean cold water at each change, paying special attention to cleansing of the genitals. Oils or powders must not be used to soothe the sore places, because they clog the pores and
Interfere with natural elimination.

16. A wet nurse is to be preferred to artificial feeding. She should be thoroughly healthy, not over thirty years of age, of equitable temper, not excitable or nervous and her diet should be that prescribed for the mother.

17. Care of the Nipples. They should be thoroughly cleansed before and after nursing; not with carbolic acid, but with water and dilute lemon juice. The lemon juice tends also to harden the nipples. Treatment of the nipples may begin before the birth of the child.

18. Care of the Eyes. The baby’s eyes, whether awake or asleep, should always be shielded from strong light, either sun or artificial, and from dust and wind. The eyes should be washed with cold water after every cleansing bath. If they show any tendency to weakness or disease, slight vibratory massage over the closed eyelids should be given after the cold eye bath.

19. Care of the Mouth. A healthy baby’s mouth needs no cleaning before the arrival of teeth. As a matter of fact, the teeth of a perfectly healthy adult would not need cleaning any more than do those of an animal living in the freedom of nature. The saliva is a sterilizing fluid, under normal living, intended by Nature to keep the mouth clean and healthy. Cleansing of the mouth of an infant with the finger or with a cloth may injure its delicate membranes. If the mouth must be washed, in case of disease, a swab made by twisting a piece of sterilized absorbent cotton on the end of a smooth stick should be used. The swab should be dipped in warm boiled water, and the interior of the mouth washed thoroughly, the cotton then being burned.

20. Care of the Ears. The external ear should be cleansed with a soft rag or swab as before described. Never use a hard instrument inside the ear.

21. Care of the Nose. A baby’s nose should be cleansed as a part of the daily toilet, in the same way as the ears. A swab may be made by twisting a, piece of gauze to a cone. As soon as the child becomes old enough, it should be taught to sniff up cold water through the nostrils and the nasal passages. This is the best way to keep the nasal membranes in a clean, healthy condition.

22. Care of the Genital Organs. The genital organs of both sexes must be kept scrupulously clean with as little handling as possible. The foreskin of the penis of the male baby should be drawn back at bathing time and the organ thoroughly cleansed, always finishing with cold water.

23. Phimosis. The treatment of phimosis is fully described under Sec. XXVIII, No.1.

24. How to Lift the Baby. The best way to lift a young
baby is to slip the left hand under the back beneath the shoulder, spreading out the fingers in such a way as to support the neck and head. Then lift the feet and legs with the right hand. Never lift an infant without first supporting the spine.

When a baby has grown strong enough to hold up its head and has gained considerable strength in the muscles of the back and neck, he may be lifted by grasping him with outspread fingers under the armpits; the body must be held firmly so that the entire strain does not come on the shoulders. A baby should never be lifted by the arms. This may dislocate the shoulder joints

SECTION XXXVIII

Prenatal Feeding

1. Effects of Diet During Pregnancy. The problem of infant nutrition begins before birth. Prenatal feeding determines the physical start in life. On it depends not only the condition of the mother's health during pregnancy, but also the size and weight of the fetus, pliability of the bony structures, ease or difficulty of delivery, and the quality of the mother's milk.

The fleshier and heavier the newborn infant, the prouder and happier are the parents and the doctor. Yet, excessive size and weight of the child constitute the most prominent cause of difficult and painful childbirth and frequent necessity for instrumental delivery.

The biblical saying, "In sorrow thou shalt bring forth children"; has led many to believe that woman's dreadful suffering is a necessity, God ordained; but is not man's ignorance, rather than the cruelty of an avenging God, to blame?

This latter view is confirmed by the fact that other mammalia literally cast their young, without pain or difficulty; and the labor pains of primitive mothers are insignificant, their delivery presenting little more difficulty than that of the lower animals. A squaw on the Western Plains stops a few hours by the wayside to deliver her papoose and then resumes her journey as though nothing had happened.

Women among the European peasantry, who wear no corsets, live on black bread and vegetables, and have plenty of exercise in the fields and in the home to the last day of pregnancy, have their babies without help of midwife or physician and resume their usual routine of work within a few days after delivery.

Thousands of mothers who have adopted natural ways of
living have learned to dispense with anesthetics and the surgeon's instruments; they now bring forth their offspring without excessive pain.

2. Results of Faulty Diet. It is significant that the offspring of the lower animals, at birth, consist of little more than skin and bones, while the newborn human is often abnormally large and fat. This is especially true of babies born of weak and anemic mothers. As before stated, excessive size and weight of the infant is not a matter for congratulation, but is a pathological condition. It indicates fatty degeneration of the fetus, due to the anemic watery condition of the blood of the mother, and the cause of this hydremia of mother and child lies in the faulty dietetic habits of the former.

The ordinary diet of American women consists almost entirely of meat, fish, fowl, potatoes, white bread, pastry, coffee, tea and refined white sugar. The few vegetable, which enter into the daily dietary are first deprived of their all important organic salts by faulty cooking; fruits are looked upon as luxuries and frequently are regarded as harmful

The anemic, watery condition of the blood of mother and child is not due to a lack of starchy, protein and fatty materials in food and blood, but to a deficiency of organic mineral elements. Neither is the anemic condition, as the regular school of medicine assumes, caused by lack of iron. Any ordinary food mixture, as well as the blood and milk of anemic mothers, usually contains a sufficient amount of iron. The actual cause of the anemia is a deficiency of other mineral elements.

As I have explained in Volume III of this Series, carbonic acid poisoning and the resulting sluggishness of the surface circulation, coldness of the extremities and congestion of the inner organs is not caused so much by a lack of the oxygen-carrying iron as by a deficiency of the carbonic acid neutralizing and eliminating sodium and magnesium.

If the blood is deficient in lime, phosphates, silicon and fluorine, rachitic conditions, softening of the bones, deformed spines and legs, and decay of the teeth, are inevitable results.

It is an easy matter to supply the daily needs of the organism for proteids, starches, fats and sugars; the difficulty lies in supplying a sufficient amount of the organic mineral elements.

The deficiency of sodium in human blood, Dr. Lahmann proved in the following table of comparative blood analyses. In a hundred parts of ash he found in the

<table>

</table>

The percentages of lime and of other positive mineral elements in the human blood are also much lower than in the blood of cows, oxen and sheep.

While the blood of cattle and sheep raised on pasture is very uniform in composition, hardly any two samples of human blood are alike. It is for this reason that Dr. Lahmann adopted cow's milk instead of human milk as the standard elementary food combination.

In the following table, he compares the percentages of minerals in the ash of cow's milk with the percentages of mineral elements in the ash of various other food materials.

A daily dietary consisting largely of meats, eggs, white bread, potatoes, peas and beans, though excessively rich in proteids, fats and starches, will, on account of its deficiency in sodium, lime and magnesium, inevitably result in carbonic acid poisoning, anemia, rachitis, premature decay of the teeth and a multitude of other acute and chronic ailments.

If, however, the daily dietary contains a liberal amount of green vegetables and fruits, a normal food mixture resembling that of cow's milk can easily be obtained. It must be remembered that fruits and vegetables are not only rich in the most important mineral salts, but that they are relatively poor in proteids and carbohydrates.

For this reason fruits and vegetables facilitate the establishment of an equilibrium between proteids and carbohydrates on the one hand and organic mineral salts on the other.

**3. Excessive Fat Formation.** We can now understand why the ordinary faulty diet of pregnant mothers causes anemia, softening of the bones, sluggish circulation, carbonic acid poisoning and fatty degeneration in mother and offspring.

Lack of sodium causes excessive accumulation of carbonic acid, and oxygen starvation. This results in defective
oxidation of food and waste materials; in other words, in fat formation.

Defective draft prevents the complete consumption of coal, and chokes the furnace with the products of imperfect combustion. Similarly, lack of oxygen in the tissues (due to carbonic acid poisoning) causes an incomplete combustion of food materials and waste products, resulting in fat formation and in the generation of poisonous byproducts.

Lack of sodium also prevents the neutralization and elimination of uric and other acids and ptomaines (pathogenic matter) which accumulate in the tissues, block the circulation and assist in the smothering of the vital processes.

In order to eliminate these pathogenic materials, there arises an abnormal craving for water—"the anemic thirst"—which is closely related to the thirst of fever patients and of diabetics. Excessive water drinking is encouraged by the popular "flushing" fad.

To make things worse, the anemic, for reasons before stated, usually suffers from weak heart action and sluggish circulation. This means defective elimination of water through the skin and kidneys, resulting in a watery (dropsical) condition of the tissues and fatty degeneration.

Not all anemic, carbonic-acid-poisoned mothers, however, develop a tendency to obesity. On the contrary, under certain constitutional conditions, they may become exceedingly lean, like the anemic, carbonic-acid-poisoned consumptive. Briefly stated, sluggish heart action and weak kidneys favor retention of carbonic acid and water in the tissues and thus make for fatty degeneration. Good circulation and normal activity of the kidneys may keep the system free from excess of water and carbonic acid, but excessive proteids in the diet may result in sulfuric and phosphoric acid poisoning. These destructive acids break down the tissues, rob them of their mineral constituents, and thus cause excessive loss of flesh and fat.

In both types of dysemia the blood of the pregnant mother is overloaded with poisonous gases, waste matter and the debris of broken-down tissues. The oxygen supply to the fetus is therefore very much impeded and we find that both fleshy and lean mothers produce babies of abnormal size and weight, ranging from eight to twelve pounds, while the normal weight of the newborn should not be more than six pounds.

4. Advantages of Natural Regimen. We know of many instances where mothers, after having given birth to heavy, fleshy babies, in subsequent births have reduced the weight of the new born to normal, and the pain of delivery to a minimum, by the adoption of a natural diet, plenty of exercise in the fresh air and systematic deep breathing.
The effects of a natural regimen are manifested in various other ways. The bony and muscular structures of mother and child are much more pliable and elastic, making parturition and delivery much easier. Pure blood, normal nutrition and abdominal exercises, walking and special gymnastics, greatly strengthen the abdominal and uterine muscles, thus facilitating expulsion of the fetus.

The morning cold rub, systematic deep breathing and general exercises, every day outdoor walks and right mental and emotional attitude are all of paramount importance in the regimen of pregnancy.

The Regimen for Wholesome Living, section I, is admirably adapted for all the needs of the pregnant mother.

SECTION XXXIX

Postnatal Feeding

Thanks to the educational influence of nature cure propaganda, a decided change for the better in baby feeding has taken place during the past ten years. Up to that time the "top cream mixture" was universally recommended by allopathic physicians and given to babies by trained nurses.

While in the meantime many physicians and nurses have adopted more natural methods, the "top cream mixture" is still too common and must be entirely abolished in order to safeguard the health of our little ones.

In the February, 1909, issue of the Nature Cure Magazine, I commented upon this subject as follows:

1. Bottle-fed Babies. Our food analyses disclose the interesting fact that the elementary composition of the ash of the milk of an animal is about the same as the composition of the ash of its body.

They also show that good cow's milk when normal comes closer to the requirements of the infant body than does inferior human milk.

Our tables of food analyses show that chemically the composition of cow's milk and of human milk is very much the same. Human milk contains a little less proteid and a little more sugar than cow's milk, and the latter is much richer in organic salts than the former. There is much more of the all-important sodium in cow's milk than in human milk and about twice as much calcium (lime) and iron (table p.100). This explains why rachitis is so common among babies, while never found among calves.

As we have learned, the elimination of poisonous acids
from the body depends on sodium. The building of the bony structures depends on lime; the oxygenation of the blood, on iron.

Many years of practical experience in the care of babies has convinced me that milk fresh from a healthy cow is greatly to be preferred, as nourishment for infants, to the impoverished milk of scrofulous mothers.* In this connection it is significant that one-half of all "civilized" mothers, thanks to unnatural food and drink, vaccination and poisonous drugs, are incapacitated for nursing their offspring.

* This may not be true in the future if our milk cows continue to be regularly subjected to tuberculin tests.

To one who has studied the comparative analyses of cow's milk and human milk, it is incomprehensible why the former, when given to infants, should be diluted and spoiled by large quantities of water, salt, soda and inorganic mineral lime (in the form of lime water).

This procedure, however, is still frequently recommended by physicians of the regular school. Undoubtedly, the great frequency of anemic and rachitic diseases, the darkening of the iris, appearance of scurf rim, and the signs of catarrhal conditions in stomach and bowels are caused by such unnatural feeding.

The following extracts are taken from an article entitled "Bottle-fed Babies", in the Ladies' Home Journal. It was written by Dr. Emelyn Lincoln Coolidge, of the Babies' hospital, New York. Thousands of mothers, on account of the high standing and excellent reputation of this family journal, undoubtedly have followed, without question or misgiving, the advice presented.

The formulas given below are for the average healthy baby, and are called "cream" or "top milk" mixtures.

"Food for the first month. With a spoon, or a tiny dipper which comes for this purpose, carefully skim off the top six ounces from a quart bottle of milk; to this add twenty-four ounces of water which has been boiled and cooled, and in which has been dissolved three teaspoonfuls of granulated or six of milk sugar; next add a pinch of bicarbonate of soda and a small pinch of salt; mix this all thoroughly, and pour enough for each feeding into ten separate bottle& Then cork the bottles family with cotton and either Pasteurize the milk or stand it on the ice.

"For the second month. Skim off six ounces of cream, then pour off three ounces of milk; add twenty-four ounces of water and the same amount of sugar, salt and soda as above; mix and bottle.

"For the third and fourth months. Cream, six ounces; milk, six Ounces; water, twelve ounces; barley or oatmeal gruel, twelve ounces; sugar, salt and soda as usual, etc.

**Plain Milk Formulas**

"Pour the entire quart of bottled milk out into a clean pitcher and then back into the bottle several times, thus thoroughly mixing the milk; then take:
"For the first month. Six ounces of milk, twenty-four ounces of barley-water, half a tablespoonful of granulated or one of milk sugar, a pinch of bicarbonate of soda; mix all well together and pour the proper number of ounces into separate bottles, and either Pasteurize or place on ice.

"For the second month. Nine ounces of milk, twenty-one ounces of barley-water, one tablespoonful of sugar, and a pinch of soda."

Physicians would never think of giving such advice as this, if they were acquainted with natural dietetics founded on exact and complete analyses made by food chemists of the nature cure school.

I have already called attention to the fact that food chemistry, whether practiced in allopathic colleges, in great sanitariums or by vegetarian food reformers, deals with proteids, starches, fats and sugars only, and leaves entirely out of consideration the all important mineral elements or organic salts of potassium, sodium, iron, lime and magnesium.*

*This was true at the time this article was published in the Nature Cure Magazine.

On these five positive mineral salts, as we have shown, depend all the important vital functions of the human organism, while proteids, starches, fats and sugars serve only as building and fuel material.

The digestion of the proteid and carbohydrate foods, as well as the elimination of the waste matter resulting there from, depends upon the positive organic mineral salts.

Study carefully these recipes for baby feeding, taken from the Ladies' Home Journal, and compare the mixtures with the analyses of cow's milk and human milk in the accompanying tables.

Let us consider the "top milk" mixture, prescribed for the first month. The cream rising to the top is almost pure fat. The all-important mineral elements plus the nourishing milk sugar and proteids remain in the skimmed milk, which is looked upon as worthless and fed to the pigs.

Our food analyses (see tables in Volume III, Cook Book) show that the ordinary brands of flour are almost devoid of mineral elements. Furthermore, one teaspoonful of barley to one pint of hot water does not mean much in food values. Where in these six ounces of cream (fat) and twenty-four ounces of barley water is baby to get the necessary amount of sugar for fuel material, of proteid for tissue-building, of lime for bone-building, of iron for oxygen-carrying, and of sodium, magnesium and potassium for the processes of elimination?

It seems that these deficiencies are intended to be overcome by baking soda, mineral table salt and the lime water, so generally prescribed by physicians. Many times I have demonstrated that inorganic mineral salts, with the possible exception of a little table salt, should not enter the animal or human organism, that these salts must first be organized,
made alive in the plant or animal cell, before they are wholesome food for animals or human beings. I have shown that, taken habitually in the mineral form, these salts accumulate in the human body, act as irritants and poisons and reveal their presence in the iris of the eye.

I fail to understand why the tender and sensitive organism of the newborn infant should be encumbered with inorganic minerals while cow's milk contains them in ideal form, made alive first in the grasses and grains, then still more highly organized and magnetized in the body of the animal.

It is bad enough to give mineral sodium, lime and table salt to an adult, but it is little short of criminal to give them to babies under the guise of foods and medicines.

The cream mixtures are readily digested, because there is not much to digest. The fact that infants thus fed cry for food continually is good evidence that their needs are not satisfied. Babies fed with this sort of slop grow fat for a while. The watery food inevitably produces fatty degeneration. This for a season swamps the little body with unhealthy fat. But the first crisis which happens along often takes away not only the unnatural fat, but the baby also.

The artificial mixtures contain entirely too much water in proportion to nourishing elements. The resulting malnutrition and the constant irritation caused by the inorganic minerals result in chronic diarrhea or constipation.

The Right Way

The best food for the newborn and growing infant is undoubtedly the mother's milk, provided that she is herself in fairly good health. Unfortunately, many mothers are unable to nurse their offspring, and if a healthy wet nurse cannot be secured, other food must be provided.

The best substitute for human milk, without question, is cow's milk, fresh, pure and undiluted, as it comes from the animal.

"Why", indignantly exclaims the trained nurse, when we give these instructions, "undiluted cow's milk is altogether too rich, it is indigestible for baby; if the milk is not boiled or pasteurized, germs and bacilli will surely create infectious diseases".

To this we answer: Our analyses show that the difference in composition between cow's milk and human milk is not enough to affect the infant. The danger lies not so much in overfeeding on "rich" cow's milk as in underfeeding on watery milk and cereal dilutions, and in poisoning the little body with inorganic minerals.

As regards germ infection and the necessity for pasteurizing the milk, the menace to health and life is greater through
malnutrition than through germs and bacteria. Germs we
cannot escape, not even if we were surrounded on all sides by
walls of air-purifying and antiseptic materials.*

*Since the foregoing was written we have learned that low
vitality and morbid soil will develop perfectly normal
microzyma into so called disease germs.

One of the foremost French bacteriologists claims that in the
mouths of infants shortly after birth he has found almost every
disease bacillus known to medical science.

William Osler; M.D., to whom the English language is
indebted for the verb "to oslerize," says in The Principals and
Practice of Medicine on page 151, in the chapter on
Diphtheria:

"The presence of the Klebs-Loeffler bacillus is regarded by
bacteriologists as the sole criterion of true diphtheria, and as
this organism may be associated with all grades of throat
affections, from a simple catarrh to a sloughing, gangrenous
process, it is evident that in many instances there will be a
striking discrepancy between the clinical and the
bacteriological diagnosis."

In the first part of this sentence he states that bacteriologists
regard as the sole criterion for the diagnosis of diphtheria the
Klebs-Loeffler, or diphtheria, bacillus; in the last part of the
sentence he admits that this bacillus is found in even slight
catarrhal conditions, and he might add that it is found just as
frequently in the mouth and throat of healthy infants and
adults. This is a good example of "orthodox" scientific
reasoning.

If germs and bacilli of themselves could destroy health and
life, the human race would in a short time become extinct.
Disease germs are omnipresent. They permeate the tissues of
our bodies and in the intestinal tract swarm by millions.
Whether they prevail depends upon natural resistance,
or reserve force, and upon the disease soils in the system. The air
we breathe is saturated with all sorts of disease germs or their
microzyma.

Since baby cannot escape germ invasion, the real problem is
how to increase the resistance of the little organism and how
to purify it of morbid matter so that disease germs will not
find anything to feed on.

Resistance depends largely upon proper nutrition. Diluted,
watery milk, contaminated by inorganic minerals, is not a
good nutrient; its nutritive value is still more reduced by
pasteurizing or boiling. Heating milk or any other proteid food
above 1500 F. coagulates the albumen, disorganizes organic
compounds, precipitates salts and dissipates the life elements.
This reduces the nourishing value and digestibility of the
milk.

Nature does not provide the young animal with boiled or
pasteurized milk, and we should not lower food values by such methods.*

* It is now admitted that pasteurization and boiling kills "newly discovered vitamins" which are the "life elements" constantly referred to in my earlier writings.

I do not wish to intimate, however, that scrupulous care and cleanliness should not be exercised in the selection and handling of the milk.

Wherever possible, secure the milk of a single healthy cow that grazes on green pastures or is fed on normal clean food mixtures. Milk from cows kept in stables and fed on brewery and distillery slops and other refuse should not be used.

Every vessel and utensil with which the milk comes in contact must be carefully scoured, submerged in boiling water, drained and kept in a light, airy place.

The nursing bottle, after each feeding, must be taken apart and carefully scrubbed, inside and out, in hot water with an addition of a little soda. It should then be left in pure, cold water, until the next feeding time.

2. When to Feed. Physicians quite generally recommend feedings at stated hours, in fixed quantities.

This is altogether wrong, it establishes at once the stuffing habit, does not permit the development of natural desire and its regulation. The infant very soon becomes accustomed to eating at certain times, whether it really needs the food or not.

Food should not be given until there is an actual demand for it, which will express itself in real hunger. By careful observation and experiment the mother will soon learn to distinguish the ordinary crying of the baby and the desire for food expressed by it. If this practice of feeding only when there is a natural desire for food is strictly followed, the infant will soon establish its own regular feeding times, usually at intervals of about three or four hours in the daytime. The stomach digestion of a feeding of milk will require about three hours, therefore a minimum of that much time should be allowed between feedings after the first few weeks.

If the mother can nurse her baby, it should be put to the breast upon awakening from its first sleep, either before or after bathing and dressing.

The first secretion of the breasts (colostrum) is not really a food, but performs an important function in cleansing the intestinal tract and preparing the digestive system to properly digest and assimilate the milk when it comes, usually about the third day.

3. How to Feed. If artificial feeding must be resorted to, no food at all should be given, except a few teaspoonfuls of water, during the first twenty-four hours after birth. During
the next few days, cow's milk should be given, well diluted—about one-half milk and one-half filtered or boiled water. From week to week the amount of water should be reduced until at the end of the second month the baby takes cow's milk undiluted.

4. Night Feeding. In the nighttime feeding should not be encouraged. During the first four months it is advisable to feed not more than once during the night. After that the child should be weaned from the habit entirely. This will be facilitated by giving a drink of water instead of milk.

5. Amount of Food. Discretion should be observed in determining the amount of food. Do not induce the baby to take as much as possible, rather as little as possible. Its welfare does not depend upon the amount of food consumed, but upon the amount which it can easily digest and assimilate.

When more food is given than the digestive organs can take care of, the entire mass may ferment and sour.

6. Grain Extracts. If undiluted milk proves too rich, grain water may be added. In order to prepare this, take clean grain as it comes from the field, crush it in a hand grain mill or a new coffee mill, take three tablespoonfuls of the crushed grain to one pint of cold water, and boil on the stove for one hour; or in the fireless cooker for two or three hours, in which ease use a little more water at the start. While the gruel is boiling over the fire, add enough water to allow for evaporation and absorption. When thoroughly cooked, strain the gruel through a fine cloth or sieve. Add one tablespoonful, or more if necessary, to each milk feeding.

When baby is constipated, add to the milk, grain extract made from oats, and frequently cool the bowels with cold water. This will cure the most stubborn constipation. If the bowels are too loose, add to the milk, extract made from barley or wheat.

The small particles of hulls in the grain extracts improve digestion and evacuation, in a mechanical manner. They permeate the curds and keep them from coagulating too solidly, thereby facilitating the penetration of digestive juices; they also exert a mild stimulation on the walls of the intestines, thereby increasing the peristalsis of the bowels and evacuation of feces.

7. Baby's Natural Medicines. Fruit juices and scraped raw ripe pear or apple and the pulp of cooked fruits such as prunes or figs without addition of sugar or sweetening of any kind, are baby's finest medicines. They increase the supply of organic salts for blood, nerve and bone building and for purposes of elimination. They are nature's own chologogues, laxatives, tonics and antiseptics. They keep the little body sweet and wholesome. All babies under our care receive fruit juices beginning with the second week.
During the first two months, give one teaspoonful of orange juice, grapefruit juice or prune juice, one hour before or after each nursing. After the second month, gradually increase the amounts of fruit juices and begin to add raw pear or apple scraped with a spoon or dull knife, or the mashed pulp of fully ripened peach or grapes.

8. Weaning the Baby. Nursing infants should be weaned from the breast after the eighth or ninth month. From the sixth or seventh month, both nursing and bottle-fed babies should begin to take some solid food. The best of these to begin with are whole-grain cereals, gruels, raw and cooked fruits and tender vegetables in small amounts. Mealy baked potato is one of the best foods, better than the cereals.

9. Feeding After First Year. After the lapse of the first year, the solid foods are gradually increased and the milk reduced in quantity. Eggs should not be given before the eighteenth month, then soft-boiled or poached. During the second and third year half an egg twice or three times a week is sufficient; after that an egg at a time may be given once or twice a week.

Meat and all other foods prepared from the dead animal carcass are bad enough for adults, but it is inexcusable to give them to tender infants and children.

Dog fanciers, when they sell a valuable canine, usually advise the buyer not to give the animal any meat before the second year, lest it become a victim of distemper; and dogs are naturally meat eaters.

Well informed physicians now generally advise not to give meat to children before the fifth or sixth year. They have learned this much from the nature cure people.

Foods undoubtedly have a powerful influence, not only on the physical body, but also on the mentality and the emotions. These problems will be interesting subjects of investigation for the food chemist and psychologist of the future. In general, we may say that flesh foods are stimulating and feed the passional nature, while fruits and tender vegetables refine and stimulate brain and nerve matter as well as the intellectual, emotional and spiritual activities. Cereals, nuts and pulses build and repair the physical body and supply the body with heat and muscular energy.

The majority of animals adhere strictly to one kind of food, and therefore faithfully exhibit in their mental and emotional characteristics the effects of different food materials. Ferociousness we find personified in the carnivorous bulldog, lion, tiger and panther (that is why soldiers are fed on meat three times a day); gluttony and omnivorous voraciousness in the hog, chicken and hyena; cold-blooded cunning in the fox, and cruelty in the cat. The intelligence of the carnivorous animals displays itself mainly in the cruel cunning with which they stalk their living prey. It resembles in quality the low
intelligence of the human criminal.

Personifications of great physical strength, intelligence, endurance, patience, gentleness, fidelity, affection and self-control, we find among the vegetarian animals. The beaver, the arboreal ape and the elephant are especially noted for their intelligence; deer, antelope and sheep for gentleness; the horse for its almost human intelligence, affection and fidelity; oxen, elephants and camels for their great strength and endurance.

**Meat is detrimental to the child in every way**, physically, mentally and morally. The poisonous acids and alkaloids which it contains clog the capillary circulation, causing anemia, coldness of the extremities and defective elimination through the skin. This results in congestion in the interior organs, high blood pressure in brain and heart, headaches, nervousness, irritability, tendency to fevers, inflammations and catarrhal conditions.

With the meat, the child often absorbs the eggs of worms, tubercular bacilli, and other parasites and disease germs. Certain forms of epilepsy, St. Vitus' dance and hysterical conditions are due to uric acid poisoning and to other pathogenic materials and ptomaines contained in flesh foods. Such patients, in times of crises, frequently emit pronounced odors of raw meat or uric acid. Strictly vegetarian diet, combined with other eliminative natural methods of treatment, cures the majority of these cases.

Most of these poisonous acids, alkaloids and ptomaines contained in the flesh of dead animals are powerful stimulants. I have frequently noticed that people who have abstained from meat for a long time, when they first partake of it again experience sensations and exhibit symptoms resembling those of alcoholic intoxication.

We have learned that these stimulating extractives of flesh foods chemically closely resemble caffeine, thein and nicotine. The use of one or more of these stimulants invariably creates a craving for the others. This explains why a heavy meat eater is usually a confirmed coffee drinker or inveterate smoker, and vice versa; and why we find it almost impossible to wean people from one of these stimulants as long as they persist in taking the others.

The legumes or pulses—peas, beans and lentils—are close seconds to meat in acid-producing qualities. Eggs contain considerable ready-made uric acid and a great deal of sulfur and phosphorus. These may become dangerous to the organism. For these reasons, meats, legumes and eggs are always danger foods for the child.

Children brought up on such foods will show the effects in nervousness, irritability, lack of self-control, craving for cigarettes and alcoholic stimulants. The most serious aspect of this question lies in the stimulative influence of meat poisons.
on the sex centers. It is a well known fact, verified by close
observation, that flesh foods stimulate the sexual passions to a
marked degree. This tendency is greatly increased by the use
of coffee, tea and alcoholic stimulants in the form of wines,
liquors or medicines. If the sensitive nervous organism of a
child is overwrought by these powerful irritants, there can be
but one result; precocious sexual awakening.

From the third year the child may gradually adopt with
slight appropriate modifications, a diet as outlined under Sec.
I, No. 10, and Sec. X, No.7.

SECTION XL

Exercises in Infancy

1. Exercises in Infancy. Proper exercise is important from
the very beginning of life. A baby will follow its natural
instincts for exercise if allowed to do so, by working its arms
and legs and writhing its little body in all directions, if not
unduly hampered by tight clothing and bandages. A few nude
air baths every day will afford excellent opportunity for
baby's gymnastic stunts.

After he is a few months old he may be placed on his
stomach, when he will exert himself vigorously by trying to
raise his head, to turn around, or to raise himself with his
arms. He will soon learn to roll over and to creep lie nay now
be pulled up gently by his arms and lowered again a number
of times in succession.

When three or four months old he may be lifted by one arm
or by both arms; by the right arm and left leg, or by the left
arm and right leg. When the baby is six or eight months old,
he should be strong enough to rise from his back to a sitting
position. This may be encouraged by holding down the feet. I
have known a number of nature cure babies who at six
months of age clung tightly to a stick while being lifted a few
feet from the bed. Another good exercise greatly enjoyed
by the youngsters is to roll them back and forth on a bed.

The average healthy child will secure ample exercise while
learning to walk and run and while playing with simple toys
or with other children; but this may be supplemented to good
advantage by special exercises devised by the father and
mother. Nothing is better for the health and happiness of both
parents and children than to join in merry romp and play.

Between two and five years of age the child may be taught
more difficult stunts, performed either by himself or with
the assistance of the father or mother; but swinging the child
high overhead, throwing him up and catching and other
dangerous tricks should be avoided. They are risky and
have very little effect in developing the body of the child. The
best exercise at this age consists in outdoor play and games.
From the sixth year, the question of exercise becomes a more important one, especially since the children are confined for many hours in school rooms. If exercise at this time of life, through play and games and special gymnastics, is neglected, it may affect health, strength and efficiency of the child for life.

Those of good physique and ample strength may gradually take up and practice The exercises for adults outlined in sections XXI, XXII, XXIII, XXIV.

2. High Chair. A baby should not be put in a high chair until he is quite well able to hold the spine and head erect, and should never be left in a chair for any length of time. If a baby is forced to maintain a rigid, sitting position for a considerable time, before the bones and muscles are sufficiently developed, this may produce deformity of the spine. Maids and nurses, if not properly supervised, sometimes fasten a baby in a high chair and leave him there to take care of himself for long periods.

3. Toys. Since most babies have a habit of putting everything into their mouths, toys must be selected that can do no harm. They should have no paint, no sharp points or corners which might hurt the eyes or mouth, and must be of material which can be easily and thoroughly cleansed. Hairy and woolly playthings are unsafe, being unclean and germ carriers. Objects small enough to be swallowed must never be put within baby's reach. The simpler the playthings the better; a few clothespins, empty spools, or other simple objects are better than expensive toys.

SECTION XLI

Baby's Ailments

1. Hernia As a result of a weakly or sickly condition of the mother during pregnancy and of faulty prenatal management, many children are born ruptured. So far I have not known a single nature cure baby that was born ruptured. Such defects are due to weakness of the tissues. This results from mineral starvation. The tissue walls contain too much mortar (protein) and not enough building stone (mineral salts). Prevention of hernia, therefore, lies mainly in proper diet of the pregnant mother, but all the rest of the prenatal regimen described in these pages is of great importance in preventing this and other ailments and deformities.

There are three principal points at which rupture or hernia may take place in infancy—at the navel, in the groin, and at the line between the navel and the lower end of the sternum. Other kinds of ruptures are extremely rare.
2. **Umbilical Hernia** This is a protrusion of the intestine at the navel. It is the most common rupture in infancy. Pulling on the cord during childbirth, urging at stool or violent crying may result in rupture. The umbilical ring first expands and this forms a pouch into which one of the folds of the small intestine protrudes.

Treatment: Of primary importance is the diet as outlined herein. The baby must have plenty of fruit juices in order to reinforce the mineral salts in the milk. Cold bathing is very beneficial. The rupture itself should be cleansed several times a day with warm water. This must be followed by a wash with cold water mixed with lemon juice. Gentle, passive exercise, such as raising, lowering and twisting the limbs from side to side, also raising and lowering the body while supporting the shoulders and head, is of especial value.

The rupture must be reduced and kept from protruding by placing over it a large button or other article of similar shape, wrapped in gauze and held in place by broad strips of adhesive plaster. The adhesive tape is fastened over the button crosswise and must be applied in such a manner as to draw the skin from all sides over the rupture. Instead of the button, a compress made of gauze may be laid over the rupture and held in place by one broad adhesive strip. The covering of the rupture must be removed and renewed every day in order to allow cleansing, as before described.

When the child is old enough to exercise by himself, he should be taught special movements of the body and the limbs which develop the muscles of the abdominal region.

3. **Ventral Hernia.** This occurs along the middle line of the body between the navel and the breastbone, sometimes below the navel. The rupture may not be larger than the size of a pea or small marble, and may disappear on pressure. The treatment is the same as that of umbilical hernia.

4. **Inguinal and Scrotal Hernia** occur in infancy or in adult life; sometimes the inguinal canal does not close after the descent of the testes from the abdominal cavity into the scrotum, and the intestine descends through the open canal, thus producing the rupture. These forms of hernia become aggravated by coughing. They can be reduced immediately with gentle manipulation while the patient is lying on his back. This kind of rupture may be distinguished from hydrocele by the fact that in reducing it goes back easily with a gurgling sound. Hydrocele is not affected by coughing. A hernia is opaque to transmitted light; hydrocele, transparent.

These ruptures should be protected with a well-fitting truss. This has to be removed daily for cleansing of the parts. Appropriate exercises, passive and active, together with cooling sitz baths and washes with cold water and lemon juice are the best remedies for these, as well as of other forms of rupture.
5. **Congenital Hernia** occurs in the form of inguinal hernia and has to be treated in the same way. Ruptures of any kind must be reduced and properly supported. Constipation and consequent urging at stool may cause or aggravate any form of hernia and must, therefore, be overcome by the right treatment described under section XXVI, No.1.

6. **Colic.** This is usually caused by indigestion due to overfeeding, improper feeding, or too frequent feeding. The intestines are distended with gas, giving rise to a severe pain. The baby cries sharply, alternately drawing its legs up to the body and kicking them away. One of the quickest means of relief is a small enema of warm water and gentle circular massage of the abdomen from right to left. Food should be withheld until the symptoms have disappeared. The giving of milk or other food may quiet the attack temporarily, but the pain is apt to return with greater intensity. Warm water may be given if the baby will swallow it.

A baby managed in the natural way prenatally and postnatally is not likely to suffer from this ailment. Constipated babies are more prone to it than others.

Colic may also be caused by sudden chilling. In that case a warm bath for five or ten minutes, followed by gentle body massage will bring about a warm reaction.

7. **Convulsions.** These cause a great deal of anxiety to the fond mother. They are always reflex symptoms of some slight or serious internal disturbance due to wrong management. They commonly result from some form of auto-intoxication caused by digestive disturbances, and the resulting systemic or drug poisoning. An inactive condition of the skin, bowels or kidneys will favor auto-intoxication and convulsions. If proper care is taken to keep the system pure, and the organs of elimination in active condition, convulsions will not occur.

The best treatment during an attack is a quick, cold rub all over the body; application of a whole body or trunk pack; gentle soothing magnetic massage, and neurotherapy treatment. These treatments draw the blood into the surface and relieve congestion in the brain and nervous system.

8. **Ailments of Teething.** Many ailments of children are laid to teething, but this is a mistake. Well managed, healthy babies go through the teething period without any trouble whatsoever. This is practically always true of nature cure babies. When, however, the little body is heavily encumbered with hereditary and acquired morbid materials, food poisons and disease taints, the process of teething will not run its natural course and may precipitate any form of disease crisis.

When teething is difficult, it is frequently associated with digestive disturbances. Diarrhea may alternate with constipation and vomiting is of common occurrence. The baby may be restless and fretful. He tries continually to bite on something in order to facilitate the projection of the teeth
through the hardened gums.

No teething lotions or soothing medicines of any kind should be given for the relief of pain in teething. They all contain poisonous sedatives which benumb and paralyze the nerves and have serious after effects upon the system. They usually contain opium in some form, or other narcotic drugs.

The only way to prevent these and other infantile ailments is to keep the little body as nearly normal as possible through the natural treatment described in these pages. If this is closely adhered to, it will prevent, in many cases, the development of even measles and other common eliminative infantile ailments.

During this critical period in the baby's life the diet must be extra light; starchy food should be reduced to a minimum and replaced by raw and cooked fruits and vegetables juices. Cooling sitz baths will help to keep the bowels active and to abate internal fever.

9. Acute Catarrhal Disease. Acute catarrhal diseases of infancy such as croup, cold in the head, acute bronchitis and whooping cough, are different forms of acute elimination through which Nature tries to purify the little body from hereditary and acquired accumulations of morbid matter, systemic poisons and disease taints.

In accordance with this conception of acute diseases, as purifying, healing efforts of Nature, we would not do anything to check or suppress elimination but cooperate with Nature in her purifying, healing efforts. How we do this has been fully explained in other parts of this volume. (Section VIII)

The natural treatment is very much the same in all acute inflammatory ailments. Feeding must be reduced to a minimum. If the baby does not insist upon eating, nothing should be given except water with acid or sub-acid fruit juices, such as lime, lemon, grape fruit and orange. If the temperature does not run high, say not above 100 or 102 deg, frequent ablutions with cold water at intervals of from one to two hours will be sufficient to promote heat radiation and elimination of morbid matter through the skin and other organs of elimination. If the temperature runs' higher, say between 102 and 105 deg, wet packs must be applied, and renewed when they become hot or dry.

The wet packs are of especial value in all kinds of cough; whether it be the ordinary cough, croupy cough or whooping cough. A whole body or trunk pack, with or without a throat pack, will give almost instant relief. In many instances where baby is making the night hideous for the anxious mother, with it's coughing, a well-applied whole body pack, or a combination trunk and throat pack, will relieve the coughing almost instantly, and induce restful sleep.
In serious cases it is always advisable to call in a natural therapist or some other drugless physician, if one can be reached.

The mother should not forget that all acute diseases, after they have once developed, must run their natural course. She must, therefore, not become impatient and lose faith in the natural treatment if it takes a week or more to cure a common cold in the head or an attack of bronchitis, or if it takes from two to eight weeks to cure a case of whooping cough. Serenity, patience and cheerfulness are the primary requisites of the nature cure physician.

PART IV

BABY BOOK

Natural Therapeutics has undoubtedly solved the problem of treating human ailments. All other schools and systems will in time have to adopt the natural way. It is the hub of the healing art; all therapeutic methods radiate from it like spokes from a wheel.

Natural Therapeutics, however, has something better to give than treatment of disease, and that is prevention of disease. If children were brought into this world in the manner ordained by Nature and reared in harmony with the teachings of natural philosophy, disease would soon be a thing of the past. Human beings would then enjoy good health and be as beautiful and perfect in their kind as are animals, which live in the freedom of Nature, guided by instinct and therefore in harmony with the laws of their being.

We must begin, then, with prevention, for prevention is always easier and cheaper, than cure. But where must we begin to study the prevention of disease? Some will say, "At birth, because that is the beginning of life." Not so: that would be too late. The mould is made and the foundation laid for health or disease, for happiness or suffering, for efficiency or deficiency, before the human being in process of creation sees the light of day.

"Then," it may be said, "we must begin with prenatal influence, for the physical, mental, emotional and moral habits of the mother influence powerfully the development of the new life she is carrying." True—but we must start earlier than that. The making of the human being begins with mating and conception. All subsequent development depends upon the right start.

SECTION XXXII

Heredity

1. Importance of Correct Mating. Of primary importance in the sacred rite of procreation, as already intimated, is mating. This should take place only between descendants of the same subrace, or of closely related subraces such as the Indo-Caucasian and Celtic.

If the racial descent of the marriage partners is so far removed that it has produced pronounced differences in racial
characteristic—as in the case of the swarthy Mexican and white skinned Englishwoman, or the dark eyed Magyar and blue-eyed Scandinavian—then procreation becomes miscegenation and degenerates into mongrelization of the offspring. Everywhere in the animal and human kingdoms Nature has set the mark of disapproval on the mongrel. The offspring of miscegenation is doomed to deterioration and extinction unless assimilation of the elements of a lower race by a higher takes place sparingly and gradually.

The law of racial purity may be summed up as follows: When a member of a higher race cohabits with a descendant of a lower race, the offspring of the union loses more or less the characteristics of the higher race and reverts in physical, mental and moral traits to the level of the lower race.

The constructive results of racial purity are evident in Hindus of the higher castes; in that portion of the Jewish race which in mating has faithfully adhered to the Law of Moses, and in the blond and blue-eyed remnants of the Indo-Caucasian and Celtic races in Northern Europe and North America. The destructive results of miscegenation are plainly evident in the mongrelized population of Mexico and everywhere in the half-breed and many kinds of mixed breeds. These usually fall below the physical, mental and moral standards of the parent stock, and almost invariably revert to the customs and habits of the inferior race.

2. **Use Heredity.** Use heredity deals with the transmission to offspring of acquired physical, mental and moral characteristics of the parents. According to this law as it has been formulated, the chances of the offspring for long life, health, mental efficiency and moral stamina, other conditions being favorable, are better in direct ratio to the advancing age of the parents at the time of conception. While this is contrary to popular opinion, which assumes that younger parents produce more perfect offspring than older ones, the fact of use heredity is proved, both in the animal and human kingdom, by common observation and statistical evidence.

The working of the law is based on the fact that the procreative elements of the parents, or rather the microzyma of those elements, cannot contain the impress of physical, mental and psychical characteristics which at the time of procreation were not developed in the threefold organisms of father and mother.

The age of the father at conception is called the "birth age" of the offspring and determines its birth rank. While the father and previous male ancestors, for reasons hereafter explained, seem to exert greater control over the mental and physical characteristics, the mother furnishes the nutrient soil for physical growth. This does not mean that she exerts no control over the mental and psychical characteristics of the offspring; in addition to her influence through use heredity she has added opportunities through prenatal influence and postnatal training.
According to this law, then, the chances of the offspring for excellent physical, mental and moral development become better as the age of the father at the time of procreation advances beyond thirty five; while the physical condition of the mother for reproductive function is best below thirty five years.

But we must not overlook the fact that too great a discrepancy of age between the man and woman may become the cause of physical and mental incompatibility, of aversion and great unhappiness, especially on the part of the younger woman.

Extensive statistical evidence seems to prove that the birth age of the mother has been of less importance than that of the father. As will be shown in Natural Eugenics, the majority of famous men in all lines or human endeavor had old male ancestors, while the mothers and previous female ancestors were of much younger age at the time of conception.

This may be accounted for by the following reasons:

The man is usually considerably older than the woman at the time of marriage. Men, as a rule, devote much more time and effort to acquiring a scientific, professional or business education than do women. This has been true in the past more than it will be in the future. Thrown early into the competitive struggle of life men generally have had to make greater mental and physical effort than have women.

These points are of considerable importance because it has been proved that it is not inherited brain mass and mental capacity, but strenuous and persistent effort that intensifies use heredity. The earlier this begins and the longer it continues before procreation takes place, the better the chances of the offspring for physical, mental and moral capacity.

The reproductivity of the mother has usually ceased at thirty-five. Though she be capable of childbearing a few years longer, usually conception has been avoided after that age. Men under favorable conditions remain reproductive to advanced age. Some of the world's greatest men descended from fathers over sixty years old.

That intellectual and creative capacity has followed the male line of descent rather than the female line, is indicated by the fact that the high intellectual capacity of many eminent men has skipped their daughters to reappear in male descendants. This may be partly accounted for by the fact that the daughters in their limited spheres of activity have not had the opportunity to unfold inherent intellectual capacity to any conspicuous degree.

There has been a tendency in some quarters to criticize the general entrance of women into professional and commercial life and to dilate upon the adverse influence this will have
upon womanly characteristics and family life.

In the light of the knowledge we possess upon the subject of use heredity, it is safe to say that any such problematical drawbacks will be far outweighed by the general postponement of the marriage age. This will insure not only better physical fitness but also higher intellectual development and greater moral stamina on both sides of parentage.

The tremendous benefits which this increased hereditary endowment will confer upon future generations cannot be overestimated. Greater intellectual and economic equality between the sexes will emancipate woman from degrading sexual subservience. Under the old order, sex appeal was too often her only stock in trade by which to attract and hold the male and thus to secure a living. Economic independence will insure greater consideration and higher esteem for the woman on the part of the man. It will go a long way toward solving the problem of birth control in a natural way, by leaving it more largely to the judgment of the mother.

We find the law of use heredity according to birth age verified in the intelligence and moral development or obliquity of races, nations and tribes all over the earth—The lower the average birth age of a race or nation, the lower, other things being equal, the intellectual and moral development The greatest development and efficiency is found among those nations where marriage is delayed to a later age through custom, economic necessity, professional or military training.

The following quotation from "Control of Heredity", by Casper Lavater Redfield, is of interest in this connection:

"In general it may be said that wherever there are no restraints upon the sexual propensities, as with the Digger Indians, the Fuegians, the Andamanese, the Wauraus of the Guianas, the Bushmen and the tribes along the Gabbon river, there we find reproduction taking place at the earliest possible age, and the lowest grade of intelligence. Where we find some special circumstances or customs that delay the age at which reproduction takes place, as with the Patagonians, the North American Indian and the Polynesians, there we find considerably higher grade of intelligence.

"Where we find the custom of marrying late in life, as was customary with the Greeks and the Romans, there we find a very high grade of intelligence. And where we find a fortuitous succession of very late births, there we find the very great men of the world's history.

"In other words, the longer the time in which the individuals have in which to use, develop and strengthen their brains before reproduction begins, the greater and more powerful are the brains of their descendants."

In Volume IV of this Series I shall quote elaborate and
highly interesting statistics from Redfield, which reveal the
effects of the various birth ages on physical, mental and moral
characteristics. I shall confine myself, for the present, to the
statement that, with few exceptions, the great artists,
scientists, philosophers, statesmen and philanthropists were
born from fathers whose ages ranged from forty to sixty-five
years at the time of the procreation of their famous offspring.

The existence of these laws and principles as facts in nature
is very evident in the training of racehorses and of other
animals along certain lines of proficiency.

3. Pernicious Heredity. The effects of deteriorating and
destructive heredity prenatal and congenital influences have
been traced and commented upon in so many different ways
that I do not believe it necessary to enter deeply into this
phase of the subject. Various authors have filled entire
volumes with the unsavory family histories of the descendants
of the Jutes, Ishmaels and other drunkards, prostitutes,
degenerates and criminals, which prove positively the
transmission of morbid and pernicious traits through
successive generations. It has been proved statistically beyond
the shadow of a doubt that youthful delinquency, pauperism
and criminality are the aftermath of immature marriages.

The laws of use heredity and prenatal influence, like all
other natural laws and principles, manifest along opposite
lines of expression. It remains for us to determine whether we
shall align ourselves with their destructive or constructive
activities. The effects upon ourselves and our offspring will
show accordingly.

If I succeed in arousing the consciousness of prospective
fathers and mothers to the glorious privileges and enormous
responsibilities which these laws of nature confer upon them,
then my labor will not have been in vain and I shall feel
deeply gratified.

SECTION XXXIII
1. The Creative Alchemy of Love and Affection

Procreation—as is the case with everything else pertaining
to the constituents and functions of the human entity—takes
place on three planes of being, the material (physical and
spiritual), the mental and the psychical planes. Which of these
elements shall predominate in the offspring depends upon the
mixture and adjustment of qualities in the triune makeup of
the mating couple. In order to fulfill the law and to draw the
divine blessing upon themselves and the fruit of their union
the partners in the procreative function must be united by the
bonds of love, or at least by the ties of true affection.
The source of creative genius is love and wisdom, and the essence of intelligence and power is sincerity and goodness. Without these, intelligence degenerates into selfish cunning, power into self-destructive brute force. The spring cannot rise higher than its source; its water cannot be pure and wholesome when contaminated by impure admixtures from filthy surroundings.

It is not generally known that use heredity pertains to intellectual and psychical qualities, as well as to the physical material. Animalism breeds nothing but selfish animalism. The vampire who craves and absorbs the love of its victims and robs them of vital energy, without being capable of feeling or bestowing affection, is the child of a discordant union—of brute animalism on the part of the man, of secret aversion and hatred, usually, on the part of the woman. These bestial and degrading tendencies on the one side, and unrequited love craving on the other, breed sex perversion, and propagate the harpies who delight in the seductive power of superficial beauty, while gloating over the weakness and ruin of their victims.

True love and affection, paired with intelligence and goodness; liberate the creative elements necessary to the production of perfect offspring.

The finer qualities of mind and soul open the fountains of life on the higher planes, liberate and harmonize the male and female procreative fluids, and charge them with the purest and most potent intellectual, spiritual and psychical elements.

The divine fire of creative genius burns only in the love aura of truly mated couples. It is true that these are rare under our artificial, unrighteous social institutions, and that accounts for the rarity of complete manhood and womanhood.

Perfect offspring, endowed with beauty and power of body, mind and soul, destined to shed through life a radiance of health, happiness and helpfulness—to love and be loved—issues only from the union of love and affection with intelligence and goodness.

"Love lieth at the foundation" (of all that is). "Love is passion, enthusiasm, affection, heat, fire, soul—God."

To the extent that love enters into the holy rite, to that extent its attributes will be absorbed in the threefold organism of the woman and become active in the child building in her womb. While she loves her man more than ever, her most passionate affection is centered in the new being in process of development. On it she bestows the purest and best in her food and drink, in her thoughts, emotions and secret desires. Fear, worry, anxiety, jealousy and hatred are strangers to her soul; these are the emanations of the lower spheres—she lives in heaven.

Somebody endowed with deep insight into these matters has
said:

"Whatever male and female shall truly will for, hopefully pray for and earnestly yearn for, when love pure and holy is the nuptive ascendant, in form, passionate, affectional, divine and volitional, that prayer shall be granted, and the boon be given—but the prayer must precede."

What are the direct effects of the marital rite upon the participants? If the sex attraction operates on the physical material plane only, if lust instead of love presides at the matrimonial feast, then temporary gratification of erotic craving will be followed inevitably by monotony, satiety, gradual revulsion and aversion, culminating in a morbid craving for change and variety. The partners in carnal self-indulgence are intuitively aware of these tendencies to marital unfaithfulness, and, therefore, easily dominated by distrust and jealousy.

The procreative function is attended by complete satisfaction, buoyancy of body and mind and lasting happiness only when sex attraction operates on the higher and highest planes of being, as well as on the lower; when desire and impulse are operative on both sides. Thus only will the generative function fulfill its sacred purpose and confer the highest possible benefits upon parents and offspring.

The woman, being the more highly sensitized, must be responsive to the call of holy passion. To force unwilling compliance will ruin the woman, kill her love and curse her offspring. Balzac says: "He who begins with his wife by a rape is a lost man." It is impossible for a wife to love unless she is won, not forced to compliance.

2. Sexual Intercourse During Pregnancy. Sexual intercourse should be considered the most sacred function of the human entity. From the highest and best viewpoint it should be exercised only for the propagation of offspring. However, considering the present stage of ethical and moral development, temperate indulgence may not be wholly condemned. Excessive intercourse is always weakening and harmful to both participants. We must remember that the sex fluid is the carrier of the life force. It is that which constitutes strength, resistance to disease, initiative and genius. During abstinence from intercourse the sex fluids with their creative energy are absorbed through the inguinal glands into the organism and increase physical, mental, moral and spiritual capacity and energy.

Set rules for frequency of intercourse cannot be given. This must depend entirely upon individual conditions. One safe rule is that after indulgence there should be no feeling of satiety, weakness and exhaustion. The more frequent the indulgence the stronger will grow the power of habit and of passion and the greater will become the abnormal craving. It is the same with all other appetite and passions. The more frequently they are indulged, the stronger they grow, until
they attain complete control and develop into destructive habit

A free and confidential understanding in regard to these matters between those who contemplate matrimony would go far to prevent marital misery. A great deal of unhappiness arises from the fact that mates in the matrimonial union often labor under misapprehensions concerning the attitude of each toward the sex relation, and are prevented by excessive sensitiveness and delicacy from frankly discussing it. (For further discussion of this subject, see page 390, Volume I.)

There is no problem of married life that needs more thorough mutual consideration and understanding than this one. Lack of it accounts for a great deal of "incompatibility," loss of love, revulsion, hatred, and the final tragedy in the divorce court.

Among animals, no female allows intercourse after conception. In this respect as in many others, man has sunk below the natural standards of the animals. No greater crime can be committed against the woman and the unborn life.

It is a sad commentary on our system of education, scholastic as well as religious, that our young people are not instructed before and after marriage in these all important laws of Nature. To do this should be the province of the priest who unites them in marriage, or of the family physician, if the parents have failed in their duty.

It is well known (notwithstanding the denials of medical skeptics) that the unborn infant may be "marked" by transitory impressions, especially by strong emotions; that even insignificant parental characteristics are reproduced in the offspring. Is it any wonder, then, that the most powerful of human emotions should leave its impress on the growing brain and sex centers of the fetus, causing abnormal and precocious sex consciousness?

All too often is sex perversion born and bred in bone and flesh, before the child sees the light of day. The mother cannot be blamed for this "slaughter of the innocents"; she has not been instructed on the subject. Though she intuitively senses the horror of it, she submits, in order to maintain her hold upon the man—and many a life is thus cursed before it is born. The fault lies primarily with those of the medical profession who teach our young men that the free indulgence of sexual passion is not only legitimate, but a necessity to manly vigor.

This dictum of pseudo-science is almost universally concurred in by spiritual guardians. **No greater lie was ever promulgated from the blackest abyss of Hades.** If our young men were taught that greater happiness is to be attained by the exchange of tender affection than by the indulgence of the coarser animal appetites, that the creative forces thus preserved develop and strengthen their own finest capacities
of body, mind or soul, they would wisely and chivalrously protect mother and child, at the same time conserving their own physical and moral integrity.

In no other way is it possible to call forth the deepest gratitude and unfailing esteem of a true woman. Many a man whom we have thus advised has become a lifelong friend in consequence.

3. Limitation of Offspring. I believe that the unlimited production of offspring, encouraged in some quarters for swelling the ranks of religious bodies or for increasing tax paying and cannon-fodder material, is a misfortune, both to the family and to society. Limitation of offspring, in accordance with the means and circumstances of the parents, is not only justified but should be encouraged. In any case, the production of offspring entails great responsibility upon the parents and if they cannot properly comply with the needs and rights of their children, they fail in their responsibility and duty.

Any method, however, which interrupts intercourse or prevents conception in an artificial way, is absolutely to be condemned, because this has very harmful and positively destructive effects upon the physical, nervous and mental organism of those who thus try to cheat nature by the suppression of a natural process. In our professional work we frequently meet the victims of such pernicious practices. The ordinary contrivances for prevention make of intercourse something akin to masturbation. This is also true of intercourse without orgasm which is strongly advocated under various guises. The use of poisonous antiseptics and germ killers in warm water douches is not essential for prevention, and is highly injurious. These chemicals have a tendency to poison the sexual organs and to produce in time atrophy, many kinds of female disorders, and tumors. Undoubtedly the greater number of so called female troubles and malignant tumors in later life are caused by curetments, antiseptic douches and the use of poisonous drugs, for producing abortion. The only legitimate methods of birth control are abstinence or common cleanliness.

There is nothing more conducive to the physical, mental and spiritual health and development of a woman than childbearing and child rearing in harmony with Nature's laws, as outlined in these volumes. Under favorable conditions it is not a thing to be dreaded, but to be looked upon as the greatest of blessings and opportunities in the life of a woman. Natural philosophy and practice takes these problems of progeneration, childbearing and childrearing out of the domain of uncertainty and haphazard management with its dire consequences, and makes eugenics the most exact of all sciences and the sublimest and most enjoyable of all the arts.

4. Determination of Sex. Numerous theories have been advanced concerning this interesting subject. Many attempts have been made to wrest from Nature the secret of sex
determination and numerous more or less ingenious methods have been recommended for sex control.

I know of one method only which seems to have a rational basis and which has proved of practical value. Observations seem to prove that the right ovary liberates male ova only, while the left ovary discharges female ova. The two ovaries discharge ova only at alternate menstruations.

With this data at hand, it is possible to determine the sex of a child after one birth has taken place. Suppose the first child was a boy. By consulting our pregnancy table (page 377) we can determine when the last menstrual discharge took place. This menstruation liberated a male ovum; the next menstruation would liberate a female ovum, the next a male, etc.

Thus, using the last menstruation period before the last conception as a fixed point, it would be possible, figuring from period to period, to determine the sex nature of the ovum to be discharged at each following menstrual period. Account is taken of all regular periods during the time menstruation is suspended in pregnancy. Thus, conception may be timed in such a way as to impregnate at will a male or female ovum.

This solves in a simple, rational manner another of Nature's riddles, namely, the reason for the practically equal division of the sexes.

SECTION XXXIV

Prenatal Influence

There exists just as much diversity of opinion among scientists concerning the reality of prenatal influence as about race heredity, use heredity, disease heredity and many other mooted problems of science and philosophy, which we shall study in Vol. IV of this series. In the following I shall present and examine impartially the various theories and opinions concerning prenatal influence; then we shall be better prepared to draw our own conclusions.

1. Medical Science Denies Prenatal Influence. Medical men, as usual cocksure of the correctness of their theories and hypotheses based on the "latest discoveries", deny and ridicule the possibility of prenatal influence, and relegate it to the rubbish heap of popular superstitions. They base their judgment on the fact that no nerves pass from the body of the mother through the umbilical cord into the growing fetus in the placenta, which forms the soft protecting nest of the new life within the womb. They claim that since no direct nerve connection exists between the two, mental and emotional vibrations cannot be transmitted from the brain of the mother to the brain and nervous organism of the fetus.
Are there no other means of communication between the mind of the mother and the brain of the unborn!

In the volume dealing with Eugenics we shall learn how universal intelligence and creative will become individual intelligence and personal will.

Cosmic vibrations do not flow into the gray matter of the human brain over coarse physical nerve tracts. They come over the psychical wireless which connects the human soul with the world Soul, the individual intelligence with the universal or cosmic intelligence the human will with the divine will.

Since, as proved by modern brain and nerve anatomy, immaterial cosmic intelligence and "power to will" fashion the brain of the mother into physical material centers for the expression of human intellectual faculties, capacities and powers, why cannot these cosmic vibrations act in like manner over the psychic wireless through the soul and mind of the mother on the brain and nervous system of the fetal organism?*

These epoch making discoveries and revelations of modern brain anatomy are explained in Vol. IV of this Series, *Natural Eugenics—Man Building on the Physical, Mental and Moral Planes.*

Why should the wireless, which transmits impulses of intuitive intelligence from the great source of all intelligence and creative energy into the soul of the mother, cease to operate at that point, and fail to transmit its message to the brain and nervous system of the fetus which is most intimately related and connected with the organism of the mother?

What about the phenomena of hypnotism? Absolute control of the subject's mind, through the intelligence and will of the hypnotist does not depend upon the existence of an umbilical cord and physical nerve connection between the two. The hypnotist, by silent command, may call his subject from a distance, far beyond the reach of his voice.

People telepathically attuned may communicate in like manner, spontaneously, or by conscious intent. Why then should we doubt the possibility of vibratory correspondence between the mental and emotional conditions of the mother and the plastic nervous organism in process of development within her womb?

If a complexity of sound can impress itself permanently upon the wax cylinder of a phonograph, or what is still more marvelous, if the photographic rays of passing scenes can be fixed and retained in the picture film, why should it be impossible for the mental and emotional vibrations of the mother to impress and modulate the molecular and cellular constituents of the fetal brain and nervous organism?
I have compared this creative power of the mother mind to the process of electrotyping. As the particles of metal in suspension in the fluid adhere to the spoon that is to be coated with silver, so the atoms and molecules in the gray matter of the brain of the fetus group themselves in harmony with the thought forms and emotional vibrations of the mind and soul of the mother. While this mental and psychical electrotyping takes place automatically, the mother's brain and nerve molding power can be greatly strengthened and intensified by the conscious and voluntary operation of the psychical wireless that establishes vibratory oneness between her and the human entity in process of development within her own body.

Thus it is revealed how a brain prenatally refined, organized and fashioned may endow the nascent individuality with certain aptitudes and talents along established paths of cerebration. There surely will be less resistance along such lines of physical, mental and moral endeavor than along other lines not prenatally influenced and molded. Therefore I strongly advise mothers, pregnant with new life holding marvelous possibilities for good or evil, not to be influenced by the superficial reasoning of materialistic science, but to follow the sacred intuition and impulse of their own creative genius in this, the most holy function of their being. Every normally constituted mother is intuitively aware of this wonderful power, and is willing and anxious to exercise it when her consciousness has been aroused to the great possibilities and responsibilities which the divine privilege of motherhood confers upon her.

It is natural for us to admire a great artist who portrays the human form, true to life, on the painted canvas, or who fashions it from inanimate stone, metal or marble; how much more grand and godlike is the creative power of truly mated parents whose privilege it is to bring into the world, and to fashion according to their highest ideals, a human being endowed with life and intelligence, with the infinite possibilities of a new center of creative activity.

Yet many mothers, totally ignorant of their divine creative privileges and possibilities, victims of physically and morally degrading marriage relations, and often filled with secret aversion or open hatred for their marital companions, pass unwillingly through pregnancy and not infrequently seek to destroy the new life. When the unfortunate victim of such marital incompatibility, conceived in passion and developing under the worst possible influences of mental and emotional discord, comes to arouse the maternal instincts of affection and devotion, then fear, anxiety and worry, like a continual nightmare, haunt the unhappy mind of the mother and impress their discordant vibrations upon the sensitive films of infant consciousness.

Compare this condition of fear, apprehension and gloom in the mind and soul of an unhappy and unwilling mother, with the joyful and ecstatic state of mind of a mother conscious of
the creative power of her intelligent will, who, from the time of mating and procreation, with accurate prescience prepares the most favorable conditions, astrologically, prenatally and postnatally for the finest development of the physical, mental and moral characteristics of the future world citizen.

The loftiest exaltation of a creative genius working in dead clay and cold marble cannot approach the ecstasy of a mother who has acquired a knowledge of the great laws which make possible the development of a perfect human being, the embryo of a master, an angel, a being destined to be godlike in its faculties, capacities and powers!

In place of fear and anguish of soul, what joy to the mother who knows that it lies within her power to prevent disease and degeneracy in her offspring; that the development of the child depends solely upon her own intelligent effort! Nothing is left to accident. Child bearing becomes an exact science, the most beautiful and inspiring of all arts and professions. Under such conditions motherhood, instead of being the greatest of hazards and hardships, becomes a divine privilege and the highest achievement of human existence and endeavor. It falls short only of the creative work of the great Universal Intelligence whose instrument of creation is the mother.

2. An Example from History. Let us consider the oft-quoted example of Napoleon Bonaparte. His mother, Lutitia Bonaparte, while pregnant with the future military genius, accompanied her husband on a military expedition, sharing with him the hardships and excitement of camp life, and the marches and battles of a military campaign. If there be nothing in prenatal influence, is it not singular that Napoleon should have become one of the greatest military geniuses of all ages, while not one of his many brothers ever exhibited enough military ability to make an efficient corporal? What was it that favored or determined the birth of the great military prodigy under these circumstances? The ancestors of Napoleon's father were not professional soldiers, nor was the father especially interested in military matters before the conception of his gifted offspring.

The dominant influences, therefore, must have operated through the singular occupation and surroundings of the mother during this particular pregnancy.

Many similar striking examples have been cited in works on prenatal influence. I myself might add many convincing proofs from an extensive experience in medical practice; but time and space do not permit. Contributory evidence may be secured from many excellent works dealing with this vital problem in human life. I may be permitted to say that use heredity and prenatal influence are distinctly manifest in the physical and mental characteristics of our three children who were born at intervals of seven and five years. Each one of them clearly mirrors in his or her physical, mental and emotional peculiarities the predominant mental tendencies, occupation and surroundings of the parents during the
respective prenatal periods. Similar manifestations of prenatal influence may be observed in almost any family.

3. Birthmarks. Medical men of late deny also the possibility of "marking" the offspring by sudden fear or shock on the part of the mother during pregnancy. Incidents of this kind, however, are of such common occurrence that it is a waste of time to refute these flippant denials.

There are good reasons for believing that such marking is more likely to occur during the periods when the menstrual flow should take place, but is suspended.

It may be argued that to mention the possibility of marking to a pregnant woman will greatly increase the probability of electrotyping violent emotions upon her offspring; in other words, that the fear of the thing will help to materialize it. This may be true to a certain extent, but we must remember that sudden shock through fear or disgust may cause the mischief anyway, whether or not the expectant mother is aware of the possibility. Understanding a danger and being prepared for it seems the best protection. The pregnant woman should study carefully section XXX, dealing with mental and emotional causes of nervous diseases, and should learn to relax to any sudden surprise and thus neutralize unpleasant and fear arousing impressions. Self-control is the royal remedy and the key to mastership.

4. Physical Influence. Now that we have studied some of the more important hereditary mental and psychical prenatal and postnatal influences, let us see how the physical condition of the mother's organism influences the brain and nerve matter of the fetus in its last stages of development, and after birth.

Materialistic science teaches that brain matter exudes thoughts and feelings, as the liver excretes bile, or the stomach pepsin. Natural science proves that mind is superior to matter, that the new born ego, by the power of intelligent volition, must fashion in the gray matter of the brain the molecular groupings or centers for the expression of intellectual and emotional activities, such as language, music, numbers, scientific and philosophic speculation.

This means that active cerebration and brain molding do not begin until after birth. But it stands to reason that the work of the nascent intelligence may be greatly facilitated or impeded by the physical condition of the brain. It is reasonable to assume that intellectual and emotional vibrations will more easily shape the gray matter of the brain into new configurations when it has been prenatally refined, organized and developed along certain lines of cerebration by use heredity and by constructive prenatal influences.

There exists a remarkable similarity between the brain molding and memory building activities of the intelligent ego and the making of phonographic records and moving picture
films. Lifelike impressions of sounds and passing scenes can be made upon the phonographic and photographic mediums only when wax and film are in a highly refined and plastic condition. When impure of substance and coarse of texture they, are not sensitive and plastic enough to register and retain the subtle and highly complex vibrations of sounds and passing scenes. In order to receive and register a great variety and complexity of sounds, the wax on the phonograph cylinder must possess a certain degree of refinement, softness and plasticity. If it is too hard and coarse it registers the loud and coarse sounds only. Such a record cylinder, exposed to a beautiful symphony executed by a great orchestra, would register and reproduce only the shrill cries of the trumpet, the rattle of the snare drum and the booming of the big horns and bass drums. The softer sounds of string, wood and wind instruments and finer shadings of tone and rhythm would be lost. With increasing refinement and plasticity, more subtle and delicate sound vibrations will be retained and reproduced.

In like manner the sensitive gray matter of the cortex of the brain must be in a pure and plastic condition in order to receive and register the impressions and impulses coming through the sensory organs, the psychic intuition and the intellectual and emotional activities of the mind. Anything in the way of physical impurity or foreign matter that tends to clog the brain, or to feed it with waste and morbid materials, or with corroding poisons, will lessen the atomic and molecular motility of brain and nerve matter, and will interfere with, or impede, the groupings and subtle transformations involved in the fashioning of brain centers through mental and emotional influences.

If the nutrient blood which feeds the brain substance of the fetus be saturated with CO₂, the benumbing, paralyzing carbon-dioxide, with clogging uric acid or the destructive acids of phosphorus and sulfur, the gray matter cannot, respond to the subtle and complex impressions and impulses from without and within.

The purity or impurity of the plastic matrix of the cortex depends upon the materials absorbed from food and drink. If these are so constituted as to create in the system excessive amounts of clogging and corroding substances, then these food and drink poisons will have a benumbing and deteriorating effect upon the sensitive gray matter of the brain, as well as upon the coarser tissues in the joints, muscles and vital organs. There is a rheumatism of the mind as well as of the joints.

A brain asphyxiated and clogged with pathogenic materials cannot be alert and active; it is too dull and lazy to think; it would much rather sleep than work; it is incapable of doing its best when its tiny blood and lymph vessels are obstructed with waste and morbid deposits which prevent the oxygenation and drainage of its delicately organized cellular tissues.
This, of course, is true postnatally as well as prenatally. A brain originally capable of the highest and finest achievements of the human mind may become utterly worthless, and may degenerate into idiocy through food, drink and drug poisoning.

Medical men tell mothers they need not worry over prenatal feeding, because the placenta, the vascular bag which forms the nest of the new life, acts as a filter which purifies the blood before it reaches the fetus. Common sense and every day experience tell another story. Even the best in the blood of many mothers is bad enough to serve as food for the new life.

The placenta does not filter out of the blood of the mother all food, disease and drug poisons. This is proved by the wretched condition of many infants, suffering from malnutrition, anemia and rachitis, after delivery. If the vital fluids of the mother are deficient in the mineral elements, or in other important nutritive substances, how can they deliver them to the fetus?

Occurrences like the following, quite common in our institutional practice, prove positively that the placenta is not a perfect filter for systemic poisons and for disease taints circulating in the blood of the mother.

One of the most pitiable cases of eczema in a little child less than one year old we traced to the fact that the mother, during her first year of marriage, had traveled with her husband through Eastern European and Asiatic countries, and during her pregnancy had been vaccinated five times while passing through localities where smallpox was prevalent. Both she and her husband had always enjoyed perfect health. The family record was excellent as far as traceable; still the body of the infant soon after birth, was covered with open bleeding sores, presenting a revolting sight. We could find no explanation for this strange phenomenon other than the many vaccinations during pregnancy. These had contaminated the blood of the mother, and through her the body of the fetus, with a filthy scrofulous taint.

The baby suffered terribly. For many months it slept but little, because of the excruciating pains. The eczematous eruptions were of a very stubborn nature; they broke forth again and again. Finally, however, after eighteen months of natural treatment, we succeeded in purifying the little body of the horrible infection. The child is now a little over three years old, in perfect health, and during the last twelve months has shown no signs of the morbid taint.

Under another section I shall describe the influence of food upon character and sex life.

To recapitulate: Purity, plasticity and motility of the highly refined and sensitive materials which make up the gray matter of the brain depend upon pure food, plenty of fresh air and exercise, and upon all other natural methods of living.
SECTION XXXV

Conception and Pregnancy

1. Conception takes place whenever the male spermatozoon joins the female ovum (egg) within the woman's womb. Normally the female organism liberates from its ovaries but one ovum each month, usually during menstruation, while the male discharges millions of spermatozoa at each orgasm.

Conception does not always follow copulation. The ovum remains in the womb and is capable of impregnation for about five days after menstruation. The spermatozoon on entering the womb may meet an ovum which has been discharged at a previous menstruation, or it may remain alive in the womb for a number of days and finally come in contact with a newly discharged ovum at the following menstruation.

The spermatozoon retains its ability to impregnate the ovum for from ten to fifteen days after its discharge into the womb. When the male and female germs merge into one another, conception or impregnation takes place. As soon as this has happened, the impregnated ovum becomes attached to the inner lining or mucous membrane of the womb and begins its new life as an embryo. The period comprising the time from the impregnation of the ovum until the beginning of labor or childbirth is called pregnancy.

The table of pregnancy on page 377 indicates the probable date of normal termination of a pregnancy, calculated from the last menstruation.

2. Exercise During Pregnancy. Unfortunately a great many expectant mothers labor under the idea that they must rest and be relieved from work and exercise. This of course is a great mistake. Light housework is good exercise. There is nothing more harmful during pregnancy than nursing "that tired feeling" by lounging idly about the house and coddling one's real or imaginary aches and troubles.

Of great benefit to the pregnant woman are all outdoor sports such as tennis, golf and other games which require vigorous exercise without straining or overworking the body. The great benefit of walking and other outdoor exercises, aside from their general invigorating effects, lies in the strengthening of the abdominal muscles and ligaments, which at delivery will greatly facilitate expulsion of the fetus.

The walk should be brisk and rhythmical, body erect, head thrown back, chest forward; the breathing at the same time should be deep and regular. These walks should be continued as long as time and endurance permit. Nothing, of course,
must be pushed to the point of exhaustion. One good long walk every day is necessary; two are better.

We all understand the necessity for a plentiful supply of oxygen under ordinary conditions, and especially in time of illness. During pregnancy the demand for oxygen, as well as for mineral salts, is doubled or trebled on account of the needs of the rapidly developing organism in the womb of the mother.

These extra demands for oxygen and ozone must be supplied by systematic deep breathing, cold bathing, outdoor walks, etc. If circumstances do not permit the taking of outdoor exercise, deep breathing should be practiced as often as feasible, at the open window.

Next in importance among gymnastic exercises is the internal massage described under section XXI, No.16.

Those exercises are especially valuable which bring into play the abdominal muscles and the muscles and ligaments of the genital organs.

3. Clothing. Clothing and the manner of wearing it profoundly influences the normal or abnormal development of the fetus, the health of the mother, labor and delivery.

At no time should the waistline be constricted by a corset or even by the ordinary skirt band. All clothing should be as loose and light as possible—one-piece under and outer garments, with the weight suspended from the shoulders, are best. If skirts are worn they should be fastened to skeleton waists of some thin cotton material. The close, heavy texture of the material from which the corset or so called "reform waist" is made is injurious because it interferes with skin elimination.

Even the slightest constriction of the waist line interferes with the free circulation and the normal blood supply to the abdominal organs, which is of especial importance in pregnancy; it also hinders the free expansion and movement of the uterus during the various stages of pregnancy.

Within the waistline are located a dozen or more important vital organs of the body. Any sort of constriction compresses these organs and pushes them out of their normal position. While this is extremely injurious to the body of a woman under ordinary conditions, it is doubly so to the pregnant mother and to the rapidly growing fetus. Undoubtedly many deformities and monstrosities are produced by unnatural constriction of the blood vessels and vital organs in the abdomen and pelvis of the pregnant woman.

If due attention is paid to the foregoing influences, labor and delivery will be brief and easy. This we have proved in hundreds of cases which have come under our management. The reason why women of civilized countries spend many
hours and sometimes days in dreadful agony of childbirth while those of primitive or savage races, as we call them, produce their young easily and painlessly as the animals do, is that primitive women live more simple and natural lives, while "civilized" mothers violate practically every law of Nature in their daily habits of living.

Civilization unfortunately stands in many respects for that which is artificial, unnatural and therefore productive of disease and suffering in all domains of life, not only as regards physical health, but social and political health as well.

SECTION XXXVI

Danger Signs During Pregnancy

1. Dropsical Swelling. Swelling of the limbs and distention of the veins of the legs during pregnancy may be caused by a tendency towards varicosity, intensified by obstruction of the circulation due to the enlarged uterus. Such a condition requires, aside from the natural regimen, careful and competent treatment.

Swelling of the limbs or other parts of the body may also be caused by incipient or advanced Bright's disease. The urine should be examined from time to time, especially if there is a swelling of the feet and ankles, or if there are dropsical symptoms in other parts of the body.

Such dangerous conditions are usually brought about through the excessive intake of starchy and protein foods which overwork the liver and kidneys and cause pathogenic dogging of the capillary circulation. This may result in uremia attended by violent and sometimes fatal Convulsions.

2. Uremia is the result of retention in the system of waste materials and poisons that should be eliminated through the kidneys and skin. Medical treatment for such conditions, aside from the administration of stimulating drags, consists in hot bathing with the idea of opening the pores of the skin.

We understand that all hot water treatment gives only temporary relief and is followed by greater enervation and inactivity of the skin. The best water treatment for systemic poisoning of any kind consists in the application of wet packs followed by cold ablutions as described in section XV.

The addition to the packs, dry friction rubs, air bath, good massage and neurotherapy treatment will aid in restoring the normal activity of skin, bowels and kidneys.

Whenever the urine contains sugar or albumen, fasting, alternating with raw food diet, is indicated. Suitable regimens are outlined in sections X, XI.
The giving of heavy food to the mother with the idea of increasing the flow of milk is all-wrong. We have found in all cases that the diet outlined in section X will produce a more copious flow of rich milk than lie "nourishing" meat diet. The best remedy for a scanty flow of milk is slow and thorough mastication of a few spoonfuls of raw crushed wheat every day.

3. Morning Sickness. One of the common disorders experienced during pregnancy is that known as Morning Sickness. One suffering from this ailment, though following a natural diet, should sip a cup of hot postum while remaining in bed. If this does not have the desired effect and if the patient has not been accustomed to drinking coffee, half a cup of black coffee with a few drops of lemon juice will quiet the irritated nerves. It is necessary after taking the hot drink to remain in bed for at least thirty minutes. It is understood that this is only an emergency measure. If continued, it will lose its good effect and work injury.

SECTION XXXVII

Labor and Delivery

At about forty weeks, exactly nine solar months, from the period of conception the fetus reaches full maturity, and labor begins. Labor is divided into three stages. During the first stage the neck of the womb becomes slowly and gradually distended and the orifice of the womb opens widely. When this has taken place, the fetal membranes burst and the amniotic liquid surrounding the fetus escapes.

During the second stage the fetus emerges from the womb.

After expulsion of the fetus, the placenta is expelled from the uterine cavity. This constitutes the third stage of labor

The first stage usually begins with more or less radiating pains in the abdomen, accompanied by dull pain in the small of the back and a drawing pain in the limbs. Sometimes women with the first baby feel these pains weeks in advance of the actual commencement of labor. At first they occur at long intervals and are of short duration, but gradually become more prolonged and more frequent. The pains are due to a cramp-like contraction of the muscular apparatus of the uterus forcing its contents downward.

Under this pressure from above, the neck and mouth of the uterus distend to their limits, and the walls become thinner and thinner. First the inner, then the outer orifice of the neck of the womb opens and the fetal membranes protrude and finally rupture, allowing the amniotic fluid to escape. Shortly after this the part of the fetus nearest the orifice, normally the
head, makes its appearance. At the present time the average
duration of the first stage of labor is six hours, but it may last
twenty-four hours or longer, depending upon the plasticity
and elasticity of the bony structures of mother and infant, the
rigidity of the cervix, and the vigor or lack of vigor of the
muscular apparatus of the uterus.

While the foregoing is true of the average delivery under
ordinary ways of living, we find that after the enforcement of
a natural regimen of living during and, better still, before
pregnancy, the entire period of labor and delivery does not
cover more than half an hour, or at the utmost from one to
two hours. Even the disadvantages of slight build and
smallness of pelvis can be overcome by the natural regimen
outlined in section X. When our youngest child was born, the
mother gave the first sign of pain at about midnight. I rose
from bed instantly, but had not time to finish clothing when
the membranes broke. Within twenty minutes after the
commencement of labor the infant was resting in my hands.

The wife of a prominent lawyer in a western city had
experienced three difficult deliveries. Each time surgical
instruments had to be used and she had suffered untold
agonies lasting from 24 to 36 hours. When she became
pregnant the fourth time the most prominent physicians in her
home city assured husband and wife that it was not safe for
her to go through another delivery, that the womb was in
worse condition than ever before therefore they recommended
surgical removal. For conscientious reasons, however, the
husband and wife did not follow the advice of the doctors, but
decided to try natural methods of treatment.

The lady placed herself under our care during the fifth
month of pregnancy. From that time on she followed strictly
the natural regimen of living and received daily the usual
hydropathic and manipulative treatments. This was continued
until a few weeks before delivery. In this case the baby was
born within an hour from the first contraction, and the mother
of the patient, who was in an adjoining room, had not heard a
sound. Many similar experiences refute the idea that it is
unsafe and injurious for pregnant women to undergo the
ordinary methods of natural treatment, such as hydropathic
sprays, sitz baths, massage, Swedish movement and other
forms of manipulation.

1. Preparation for Delivery. The diet during the last week
before the beginning of labor should be very light, consisting
mostly of fruits and vegetables. From the commencement of
labor no food at all should be given, until at least twenty-four
hours after delivery; a three-day fast is better.

In addition to a competent physician, a nurse or midwife
should be engaged. If a good neurotherapist, who has had
sufficient experience in obstetrical work, can be procured, he
should be preferred, because he can assist delivery and make
it much easier by manipulative treatment.
The nurse will make the necessary preparations and provide the various supplies needed in labor. With the first sign of approaching labor, the physician in charge should be summoned. A rectal enema of one pint or more of warm salt water (See. XVIII, No.4) should be administered. The woman should be given a vigorous cold rub and her genitals thoroughly cleansed. She may then remain on her feet and walk about, comfortably dressed, until actual labor commences.

2. No Anesthetics. The attending physician should not be impatient to hasten delivery with drugs or instruments. The use of anesthetics should be avoided insofar as this is possible. They should be employed only when absolutely necessary—that is, when excessive pain must be allayed or when surgical delivery is unavoidable.

3. Breaking of Water Bag. When the bag of water is about ready to break, the patient is placed in bed. Premature discharge of the amniotic fluid must be guarded against. An escape of the liquid at an early stage means difficult and prolonged labor, commonly known as "dry labor". Usually the membranes burst when the orifice is fully dilated. A large sponge is held in readiness to catch the out-flowing liquid.

3 a. Umbilical Cord. When the infant has been delivered, the umbilical cord should not be severed at once. Plenty of time should be allowed for the blood to transfuse itself from the body of the mother to that of the child. This is important. If the connection is severed too soon, the child begins life in an anemic condition.

The newborn baby usually greets the world with a lusty cry. It should be placed on its right side with its face turned away from the mother, care being taken that the cord is not stretched tight. As soon as the cord stops pulsating, plenty of time being allowed for blood transfusion, it is tied about two inches away from the baby's abdomen and cut a little above the ligature. The baby is now wrapped in a warm blanket and put in its crib.

4. After Delivery. Immediately after the baby is born, the nurse or attending physician gently compresses the abdomen and womb of the mother, kneading and rubbing it occasionally in order to secure complete contraction and thus prevent hemorrhage. After delivery the mother enjoys a period of rest and recuperation which usually lasts for about half an hour.

5. Afterbirth. Meanwhile the placenta becomes detached, and when the pains set in again a few contractions usually suffice to expel it with all the membranes.

The attending physician must make sure that none of it is left in the body, since this might result in putrefaction of the remains and blood poisoning. The woman's genitals should be washed with clean sterilized water.
The exhausted woman should now enjoy a deep, wholesome sleep and awaken from it in a few hours refreshed and strengthened.

In the foregoing I have not gone into the details of obstetrics and of technical management because this must be left to a competent obstetrician. I have called attention only to those points which are of special importance from the viewpoint of Natural Therapeutics and to the differences in treatment between the conventional and natural methods.

6. The Lying-In Period. The lying-in period varies from five to twelve days, according to the constitution of the mother and the care that she has taken during pregnancy. The greatest danger of the lying-in period is puerperal sepsis or blood poisoning. This condition is the result of infection occurring during labor, or it may result from the retention of parts of the placenta.

The only way to prevent this is by observing the most scrupulous cleanliness during the entire process of childbirth and during the lying-in period. When blood poisoning has developed it must be treated the same as all other acute inflammatory diseases (see section IX).

7. Care of the Newborn. The child should begin to breathe immediately after the cord is cut. If it fails to do this, the physician should lift the baby by its feet to facilitate the escape of mucous from the trachea and throat. If necessary the mucous must be removed from the throat by the insertion of the little finger, or by means of a tiny stick covered with gauze.

Breathing may be accelerated effectively by a few sharp taps on shoulders and buttocks. If this fails to bring the desired result, artificial respiration must be resorted to at once. The attendant grasps the child by its shoulders, its head resting between his palms and the two index fingers being hooked under the child's armpits. It is now swung between the physician's legs and lifted high above his head so as to be turned upside down. This is repeated from fifteen to twenty times, after which it is placed in a basin containing a few inches of warm water. Its body should then be rubbed briskly with cold water.

Father Kneipp used to take the newborn babe by the nape of the neck and the feet and submerge it quickly in cold water. This, a few times repeated, is probably the quickest way of resuscitating an asphyxiated baby.

In order to soften the cheesy deposit which frequently covers the body of the newborn, it is well to rub the skin with warm olive oil. After the greasy covering has sufficiently softened it may be removed with bits of gauze. This is followed by a cleansing bath with warm water and castile soap.
After the warm cleansing bath, the little body should be quickly rubbed down with cold water, wrapped in a soft, warm blanket and laid away to sleep until it wakens of its own accord. A normal baby should sleep for about twelve hours, and must not be disturbed to force food on it before it is ready to take it.

8. Bathing. From the first day, the baby must have a morning and evening bath. This consists, as before described, in a quick, cleansing bath of warm water and castile soap, followed immediately by a brisk cold rub. In the course of a few weeks the baby can be placed, for the cleansing bath, in a small bathtub containing a few inches of warm water. Immediately after the cleansing bath the warm water is replaced by cold water. This is taken up in the hollow of the hand and briskly applied to the little body. In this fashion the child, within a few months time, will enjoy its cold rub just as much as an adult. I have seen several such nature cure babies, but a few months old, object most vigorously to a warm bath. The cold rub is the best preventive of chilling; but care must be taken that the temperature of the room where the bath is given is not below 70 deg.

The olive oil bath or rub, often recommended for premature babies or infants suffering from malnutrition, is very injurious, because it occludes the pores of the skin and prevents the elimination of poisonous gases and other morbid materials from the body. The skin is not an organ of digestion. Olive oil, like all other foods, must enter the body through the alimentary canal where, under the action of digestive ferments, it is broken down into its component elements which are then assimilated through the intestinal membranes. Oil absorbed through the skin is not digested, and it circulates in the body as foreign matter which in this state cannot be assimilated and utilized in the system.

9. Powdering after the bath is fully as injurious as the rubbing with oils or massage creams. Powders and creams tend to clog the pores, and most of them contain poisonous antiseptics which lower the vitality of the skin and prevent or suppress elimination in the form of skin eruptions, eczemas, etc. For chafing use nothing but cold water. In case the chafing should become unusually severe and painful, through neglect by the caretaker, a soothing and healing lotion composed of one part lemon juice to two parts olive oil, may be applied a few times, until the irritation is under control.

10. Air Baths. Next to cold water, there is nothing that will invigorate baby’s skin and nervous system as will the air and sun bath. If the season will not allow the outdoor air bath, the baby should be allowed to lie nude several times a day, for thirty minutes or more, in a warm, well ventilated and sunny room.

11. Constipation. Glycerin and suppositories should never be used; neither laxatives nor cathartics. Oat extract and cooling sitz baths will produce natural movements.
12. **Diarrhea** is a form of morbid elimination, and must never be suppressed by drugs. If it is habitual, bailey or wheat extract prepared in the same manner as oat extract, is a good remedy. If the diarrhea is persistent and of a violent nature, no food at all must be given, except water with dilute acid fruit juices, until the purging ceases. Even then plenty of time must be allowed for the rebuilding of the sloughed intestinal membranes.

13. **Bandages.** Until the umbilical cord dries up and falls off, it is necessary to cover the navel with a gauze compress dipped in olive oil. This is held in place by an abdominal bandage made of soft cotton material. These strips should not be hemmed, merely torn or cut. They should be drawn just snugly enough to hold the compress in place, but not tightly enough to interfere with circulation. The, navel must be cleansed and the compress renewed twice each day. After the umbilical cord has dropped off we no longer apply the abdominal bandage. This is contrary to common usage, but is the best practice. The abdominal bandage overheats the body and interferes with the free movement of the diaphragm and the circulation of the blood.

14. **Clothing.** The clothing of the infant should be loose and light and as simple as possible. Freedom of movement is very important; binding or pressure upon any part cannot help but interfere with the circulation, and otherwise produce injurious results. The clothes should be short, in order to allow the feet and legs free play. Light weight, porous cotton materials are best for both under and outer garments. A lightweight wool petticoat may be worn when absolutely necessary to provide sufficient protection for the baby. Cotton hose and bootees may be used, but under no circumstances should such articles be of wool, because it prevents free elimination from the skin. The baby's head should not be covered out of doors, except in severe weather. At no time should a veil be placed over the face, as it will cause the infant to reabsorb the poisonous exhalations from its own lungs. All clothing should be changed each day. No garment should be starched—such a practice is not only useless but harmful.

15. **Diapers** must be provided in sufficient number to allow thorough cleansing and drying. The wet diapers should be scalded in hot water and very thoroughly rinsed in several waters afterwards. They should then be dried in the open air and sunshine. Soiled diapers must be well washed and boiled. Washing powders, soda, ammonia and other chemicals should never be used. They have an extremely irritating effect upon the delicate skin of a baby. In order to save labor and to facilitate the cleansing of the diapers, small squares of clean old linen or muslin rags, or pieces of absorbent gauze, may be placed inside. These inserts will absorb all or most of the bowel movement and may then be burned. If the skin is irritated or chafed, the parts should be sponged off with clean cold water at each change, paying special attention to cleansing of the genitals. Oils or powders must not be used to soothe the sore places, because they clog the pores and
Interfere with natural elimination.

16. **A wet nurse** is to be preferred to artificial feeding. She should be thoroughly healthy, not over thirty years of age, of equitable temper, not excitable or nervous and her diet should be that prescribed for the mother.

17. **Care of the Nipples.** They should be thoroughly cleansed before and after nursing; not with carbolic acid, but with water and dilute lemon juice. The lemon juice tends also to harden the nipples. Treatment of the nipples may begin before the birth of the child.

18. **Care of the Eyes.** The baby's eyes, whether awake or asleep, should always be shielded from strong light, either sun or artificial, and from dust and wind. The eyes should be washed with cold water after every cleansing bath. If they show any tendency to weakness or disease, slight vibratory massage over the closed eyelids should be given after the cold eye bath.

19. **Care of the Mouth.** A healthy baby's mouth needs no cleaning before the arrival of teeth. As a matter of fact, the teeth of a perfectly healthy adult would not need cleaning any more than do those of an animal living in the freedom of nature. The saliva is a sterilizing fluid, under normal living, intended by Nature to keep the mouth clean and healthy. Cleansing of the mouth of an infant with the finger or with a cloth may injure its delicate membranes. If the mouth must be washed, in case of disease, a swab made by twisting a piece of sterilized absorbent cotton on the end of a smooth stick should be used. The swab should be dipped in warm boiled water, and the interior of the mouth washed thoroughly, the cotton then being burned.

20. **Care of the Ears.** The external ear should be cleansed with a soft rag or swab as before described. Never use a hard instrument inside the ear.

21. **Care of the Nose.** A baby's nose should be cleansed as a part of the daily toilet, in the same way as the ears. A swab may be made by twisting a, piece of gauze to a cone. As soon as the child becomes old enough, it should be taught to sniff up cold water through the nostrils and the nasal passages. This is the best way to keep the nasal membranes in a clean, healthy condition.

22. **Care of the Genital Organs.** The genital organs of both sexes must be kept scrupulously clean with as little handling as possible. The foreskin of the penis of the male baby should be drawn back at bathing time and the organ thoroughly cleansed, always finishing with cold water.

23. **Phimosis.** The treatment of phimosis is fully described under Sec. XXVIII, No.1.

24. **How to Lift the Baby.** The best way to lift a young
baby is to slip the left hand under the back beneath the
shoulder, spreading out the fingers in such a way as to support
the neck and head. Then lift the feet and legs with the right
hand. **Never lift an infant without first supporting the
spine.**

When a baby has grown strong enough to hold up its head
and has gained considerable strength in the muscles of the
back and neck, he may be lifted by grasping him with
outspread fingers under the armpits; the body must be held
firmly so that the entire strain does not come on the shoulders.
A baby should never be lifted by the arms. This may dislocate
the shoulder joints

SECTION XXXVIII

Prenatal Feeding

1. **Effects of Diet During Pregnancy.** The problem of
infant nutrition begins before birth. Prenatal feeding
determines the physical start in life. On it depends not only
the condition of the mother's health during pregnancy, but
also the size and weight of the fetus, pliability of the bony
structures, ease or difficulty of delivery, and the quality of the
mother's milk.

The fleshier and heavier the newborn infant, the prouder
and happier are the parents and the doctor. Yet, excessive size
and weight of the child constitute the most prominent cause
of difficult and painful childbirth and frequent necessity for
instrumental delivery.

The biblical saying, "In sorrow thou shalt bring forth
children"; has led many to believe that woman's dreadful
suffering is a necessity, God ordained; but is not man's
ignorance, rather than the cruelty of an avenging God, to
blame?

This latter view is confirmed by the fact that other
mammalia literally cast their young, without pain or
difficulty; and the labor pains of primitive mothers are
insignificant, their delivery presenting little more difficulty
than that of the lower animals. A squaw on the Western Plains
stops a few hours by the wayside to deliver her papoose and
then resumes her journey as though nothing had happened

Women among the European peasantry, who wear no
corsets, live on black bread and vegetables, and have plenty of
exercise in the fields and in the home to the last day of
pregnancy, have their babies without help of midwife or
physician and resume their usual routine of work within a few
days after delivery.

Thousands of mothers who have adopted natural ways of
living have learned to dispense with anesthetics and the surgeon's instruments; they now bring forth their offspring without excessive pain.

2. Results of Faulty Diet. It is significant that the offspring of the lower animals, at birth, consist of little more than skin and bones, while the newborn human is often abnormally large and fat. This is especially true of babies born of weak and anemic mothers. As before stated, excessive size and weight of the infant is not a matter for congratulation, but is a pathological condition. It indicates fatty degeneration of the fetus, due to the anemic watery condition of the blood of the mother, and the cause of this hydremia of mother and child lies in the faulty dietetic habits of the former.

The ordinary diet of American women consists almost entirely of meat, fish, fowl, potatoes, white bread, pastry, coffee, tea and refined white sugar. The few vegetable, which enter into the daily dietary are first deprived of their all important organic salts by faulty cooking; fruits are looked upon as luxuries and frequently are regarded as harmful

The anemic, watery condition of the blood of mother and child is not due to a lack of starchy, protein and fatty materials in food and blood, but to a deficiency of organic mineral elements. Neither is the anemic condition, as the regular school of medicine assumes, caused by lack of iron. Any ordinary food mixture, as well as the blood and milk of anemic mothers, usually contains a sufficient amount of iron. The actual cause of the anemia is a deficiency of other mineral elements.

As I have explained in Volume III of this Series, carbonic acid poisoning and the resulting sluggishness of the surface circulation, coldness of the extremities and congestion of the inner organs is not caused so much by a lack of the oxygen-carrying iron as by a deficiency of the carbonic acid neutralizing and eliminating sodium and magnesium.

If the blood is deficient in lime, phosphates, silicon and fluorine, rachitic conditions, softening of the bones, deformed spines and legs, and decay of the teeth, are inevitable results.

It is an easy matter to supply the daily needs of the organism for proteids, starches, fats and sugars; the difficulty lies in supplying a sufficient amount of the organic mineral elements.

The deficiency of sodium in human blood, Dr. Lahmann proved in the following table of comparative blood analyses.

<table>
<thead>
<tr>
<th>Blood</th>
<th>Per Cent of Sodium</th>
</tr>
</thead>
<tbody>
<tr>
<td>Blood of oxen</td>
<td>12.41 to 31.90</td>

<td>13.33</td>
</tr>
<tr>
<td>Blood of cows</td>
<td>10.40</td>
</tr>
<tr>
<td>Blood of hogs</td>
<td>5.33 to 7.62</td>
</tr>
</tbody>
</table>
The percentages of lime and of other positive mineral elements in the human blood are also much lower than in the blood of cows, oxen and sheep.

While the blood of cattle and sheep raised on pasture is very uniform in composition, hardly any two samples of human blood are alike. It is for this reason that Dr. Lahmann adopted cow's milk instead of human milk as the standard elementary food combination.

In the following table, he compares the percentages of minerals in the ash of cow's milk with the percentages of mineral elements in the ash of various other food materials.

<table>
<thead>
<tr>
<th></th>
<th>Sodium</th>

</tbody>
</table>

A daily dietary consisting largely of meats, eggs, white bread, potatoes, peas and beans, though excessively rich in proteids, fats and starches, will, on account of its deficiency in sodium, lime and magnesium, inevitably result in carbonic acid poisoning, anemia, rachitis, premature decay of the teeth and a multitude of other acute and chronic ailments.

If, however, the daily dietary contains a liberal amount of green vegetables and fruits, a normal food mixture resembling that of cow's milk can easily be obtained. It must be remembered that fruits and vegetables are not only rich in the most important mineral salts, but that they are relatively poor in proteids and carbohydrates.

For this reason fruits and vegetables facilitate the establishment of an equilibrium between proteids and carbohydrates on the one hand and organic mineral salts on the other.

3. **Excessive Fat Formation.** We can now understand why the ordinary faulty diet of pregnant mothers causes anemia, softening of the bones, sluggish circulation, carbonic acid poisoning and fatty degeneration in mother and offspring.

Lack of sodium causes excessive accumulation of carbonic acid, and oxygen starvation. This results in defective
oxidation of food and waste materials; in other words, in fat formation.

Defective draft prevents the complete consumption of coal, and chokes the furnace with the products of imperfect combustion. Similarly, lack of oxygen in the tissues (due to carbonic acid poisoning) causes an incomplete combustion of food materials and waste products, resulting in fat formation and in the generation of poisonous byproducts.

Lack of sodium also prevents the neutralization and elimination of uric and other acids and ptomaines (pathogenic matter) which accumulate in the tissues, block the circulation and assist in the smothering of the vital processes.

In order to eliminate these pathogenic materials, there arises an abnormal craving for water—"the anemic thirst"—which is closely related to the thirst of fever patients and of diabetics. Excessive water drinking is encouraged by the popular "flushing" fad.

To make things worse, the anemic, for reasons before stated, usually suffers from weak heart action and sluggish circulation. This means defective elimination of water through the skin and kidneys, resulting in a watery (dropsical) condition of the tissues and fatty degeneration.

Not all anemic, carbonic-acid-poisoned mothers, however, develop a tendency to obesity. On the contrary, under certain constitutional conditions, they may become exceedingly lean, like the anemic, carbonic-acid-poisoned consumptive. Briefly stated, sluggish heart action and weak kidneys favor retention of carbonic acid and water in the tissues and thus make for fatty degeneration. Good circulation and normal activity of the kidneys may keep the system free from excess of water and carbonic acid, but excessive proteids in the diet may result in sulfuric and phosphoric acid poisoning. These destructive acids break down the tissues, rob them of their mineral constituents, and thus cause excessive loss of flesh and fat.

In both types of dysemia the blood of the pregnant mother is overloaded with poisonous gases, waste matter and the debris of broken-down tissues. The oxygen supply to the fetus is therefore very much impeded and we find that both fleshy and lean mothers produce babies of abnormal size and weight, ranging from eight to twelve pounds, while the normal weight of the newborn should not be more than six pounds.

4. Advantages of Natural Regimen. We know of many instances where mothers, after having given birth to heavy, fleshy babies, in subsequent births have reduced the weight of the new born to normal, and the pain of delivery to a minimum, by the adoption of a natural diet, plenty of exercise in the fresh air and systematic deep breathing.
The effects of a natural regimen are manifested in various other ways. The bony and muscular structures of mother and child are much more pliable and elastic, making parturition and delivery much easier. Pure blood, normal nutrition and abdominal exercises, walking and special gymnastics, greatly strengthen the abdominal and uterine muscles, thus facilitating expulsion of the fetus.

The morning cold rub, systematic deep breathing and general exercises, every day outdoor walks and right mental and emotional attitude are all of paramount importance in the regimen of pregnancy.

The Regimen for Wholesome Living, section I, is admirably adapted for all the needs of the pregnant mother.

SECTION XXXIX

Postnatal Feeding

Thanks to the educational influence of nature cure propaganda, a decided change for the better in baby feeding has taken place during the past ten years. Up to that time the "top cream mixture" was universally recommended by allopathic physicians and given to babies by trained nurses.

While in the meantime many physicians and nurses have adopted more natural methods, the "top cream mixture" is still too common and must be entirely abolished in order to safeguard the health of our little ones.

In the February, 1909, issue of the Nature Cure Magazine, I commented upon this subject as follows:

1. Bottle-fed Babies. Our food analyses disclose the interesting fact that the elementary composition of the ash of the milk of an animal is about the same as the composition of the ash of its body.

They also show that good cow's milk when normal comes closer to the requirements of the infant body than does inferior human milk.

Our tables of food analyses show that chemically the composition of cow's milk and of human milk is very much the same. Human milk contains a little less proteid and a little more sugar than cow's milk, and the latter is much richer in organic salts than the former. There is much more of the all-important sodium in cow's milk than in human milk and about twice as much calcium (lime) and iron (table p.100). This explains why rachitis is so common among babies, while never found among calves.

As we have learned, the elimination of poisonous acids
from the body depends on sodium. The building of the bony structures depends on lime; the oxygenation of the blood, on iron.

Many years of practical experience in the care of babies has convinced me that milk fresh from a healthy cow is greatly to be preferred, as nourishment for infants, to the impoverished milk of scrofulous mothers.* In this connection it is significant that one-half of all "civilized" mothers, thanks to unnatural food and drink, vaccination and poisonous drugs, are incapacitated for nursing their offspring.

* This may not be true in the future if our milk cows continue to be regularly subjected to tuberculin tests.

To one who has studied the comparative analyses of cow's milk and human milk, it is incomprehensible why the former, when given to infants, should be diluted and spoiled by large quantities of water, salt, soda and inorganic mineral lime (in the form of lime water).

This procedure, however, is still frequently recommended by physicians of the regular school. Undoubtedly, the great frequency of anemic and rachitic diseases, the darkening of the iris, appearance of scurf rim, and the signs of catarrhal conditions in stomach and bowels are caused by such unnatural feeding.

The following extracts are taken from an article entitled "Bottle-fed Babies", in the Ladies' Home Journal. It was written by Dr. Emelyn Lincoln Coolidge, of the Babies' hospital, New York. Thousands of mothers, on account of the high standing and excellent reputation of this family journal, undoubtedly have followed, without question or misgiving, the advice presented.

The formulas given below are for the average healthy baby, and are called "cream" or "top milk" mixtures.

"Food for the first month. With a spoon, or a tiny dipper which comes for this purpose, carefully skim off the top six ounces from a quart bottle of milk; to this add twenty-four ounces of water which has been boiled and cooled, and in which has been dissolved three teaspoonfuls of granulated or six of milk sugar; next add a pinch of bicarbonate of soda and a small pinch of salt; mix this all thoroughly, and pour enough for each feeding into ten separate bottle& Then cork the bottles family with cotton and either Pasteurize the milk or stand it on the ice.

"For the second month. Skim off six ounces of cream, then pour off three ounces of milk; add twenty-four ounces of water and the same amount of sugar, salt and soda as above; mix and bottle.

"For the third and fourth months. Cream, six ounces; milk, six Ounces; water, twelve ounces; barley or oatmeal gruel, twelve ounces; sugar, salt and soda as usual, etc.

Plain Milk Formulas

"Pour the entire quart of bottled milk out into a clean pitcher and then back into the bottle several times, thus thoroughly mixing the milk; then take:
"For the first month. Six ounces of milk, twenty-four ounces of barley-water, half a tablespoonful of granulated or one of milk sugar, a pinch of bicarbonate of soda; mix all well together and pour the proper number of ounces into separate bottles, and either Pasteurize or place on ice.

"For the second month. Nine ounces of milk, twenty-one ounces of barley-water, one tablespoonful of sugar, and a pinch of soda."

Physicians would never think of giving such advice as this, if they were acquainted with natural dietetics founded on exact and complete analyses made by food chemists of the nature cure school.

I have already called attention to the fact that food chemistry, whether practiced in allopathic colleges, in great sanitariums or by vegetarian food reformers, deals with proteids, starches, fats and sugars only, and leaves entirely out of consideration the all important mineral elements or organic salts of potassium, sodium, iron, lime and magnesium.*

*This was true at the time this article was published in the Nature Cure Magazine.

On these five positive mineral salts, as we have shown, depend all the important vital functions of the human organism, while proteids, starches, fats and sugars serve only as building and fuel material.

The digestion of the proteid and carbohydrate foods, as well as the elimination of the waste matter resulting there from, depends upon the positive organic mineral salts.

Study carefully these recipes for baby feeding, taken from the Ladies’ Home Journal, and compare the mixtures with the analyses of cow’s milk and human milk in the accompanying tables.

Let us consider the "top milk" mixture, prescribed for the first month. The cream rising to the top is almost pure fat. The all-important mineral elements plus the nourishing milk sugar and proteids remain in the skimmed milk, which is looked upon as worthless and fed to the pigs.

Our food analyses (see tables in Volume III, Cook Book) show that the ordinary brands of flour are almost devoid of mineral elements. Furthermore, one teaspoonful of barley to one pint of hot water does not mean much in food values. Where in these six ounces of cream (fat) and twenty-four ounces of barley water is baby to get the necessary amount of sugar for fuel material, of proteid for tissue-building, of lime for bone-building, of iron for oxygen-carrying, and of sodium, magnesium and potassium for the processes of elimination?

It seems that these deficiencies are intended to be overcome by baking soda, mineral table salt and the lime water, so generally prescribed by physicians. Many times I have demonstrated that inorganic mineral salts, with the possible exception of a little table salt, should not enter the animal or human organism, that these salts must first be organized,
made alive in the plant or animal cell, before they are wholesome food for animals or human beings. I have shown that, taken habitually in the mineral form, these salts accumulate in the human body, act as irritants and poisons and reveal their presence in the iris of the eye.

I fail to understand why the tender and sensitive organism of the newborn infant should be encumbered with inorganic minerals while cow's milk contains them in ideal form, made alive first in the grasses and grains, then still more highly organized and magnetized in the body of the animal.

It is bad enough to give mineral sodium, lime and table salt to an adult, but it is little short of criminal to give them to babies under the guise of foods and medicines.

The cream mixtures are readily digested, because there is not much to digest. The fact that infants thus fed cry for food continually is good evidence that their needs are not satisfied. Babies fed with this sort of slop grow fat for a while. The watery food inevitably produces fatty degeneration. This for a season swamps the little body with unhealthy fat. But the first crisis which happens along often takes away not only the unnatural fat, but the baby also.

The artificial mixtures contain entirely too much water in proportion to nourishing elements. The resulting malnutrition and the constant irritation caused by the inorganic minerals result in chronic diarrhea or constipation.

**The Right Way**

The best food for the newborn and growing infant is undoubtedly the mother's milk, provided that she is herself in fairly good health. Unfortunately, many mothers are unable to nurse their offspring, and if a healthy wet nurse cannot be secured, other food must be provided.

The best substitute for human milk, without question, is cow's milk, fresh, pure and undiluted, as it comes from the animal.

"Why", indignantly exclaims the trained nurse, when we give these instructions, "undiluted cow's milk is altogether too rich, it is indigestible for baby; if the milk is not boiled or pasteurized, germs and bacilli will surely create infectious diseases".

To this we answer: Our analyses show that the difference in composition between cow's milk and human milk is not enough to affect the infant. The danger lies not so much in overfeeding on "rich" cow's milk as in underfeeding on watery milk and cereal dilutions, and in poisoning the little body with inorganic minerals.

As regards germ infection and the necessity for pasteurizing the milk, the menace to health and life is greater through
malnutrition than through germs and bacteria. Germs we cannot escape, not even if we were surrounded on all sides by walls of air-purifying and antiseptic materials.*

*Since the foregoing was written we have learned that low vitality and morbid soil will develop perfectly normal microzyma into so called disease germs.

One of the foremost French bacteriologists claims that in the mouths of infants shortly after birth he has found almost every disease bacillus known to medical science.

William Osler; M.D., to whom the English language is indebted for the verb "to oslerize," says in *The Principals and Practice of Medicine* on page 151, in the chapter on Diphtheria:

"The presence of the Klebs-Loeffler bacillus is regarded by bacteriologists as the sole criterion of true diphtheria, and as this organism may be associated with all grades of throat affections, from a simple catarrh to a sloughing, gangrenous process, it is evident that in many instances there will be a striking discrepancy between the clinical and the bacteriological diagnosis."

In the first part of this sentence he states that bacteriologists regard as the sole criterion for the diagnosis of diphtheria the Klebs-Loeffler, or diphtheria, bacillus; in the last part of the sentence he admits that this bacillus is found in even slight catarrhal conditions, and he might add that it is found just as frequently in the mouth and throat of healthy infants and adults. This is a good example of "orthodox" scientific reasoning.

If germs and bacilli of themselves could destroy health and life, the human race would in a short time become extinct. Disease germs are omnipresent. They permeate the tissues of our bodies and in the intestinal tract swarm by millions. Whether they prevail depends upon natural resistance, or reserve force, and upon the disease soils in the system. The air we breathe is saturated with all sorts of disease germs or their microzyma.

Since baby cannot escape germ invasion, the real problem is how to increase the resistance of the little organism and how to purify it of morbid matter so that disease germs will not find anything to feed on.

Resistance depends largely upon proper nutrition. Diluted, watery milk, contaminated by inorganic minerals, is not a good nutrient; its nutritive value is still more reduced by pasteurizing or boiling. Heating milk or any other proteid food above 1500 F. coagulates the albumen, disorganizes organic compounds, precipitates salts and dissipates the life elements. This reduces the nourishing value and digestibility of the milk.

Nature does not provide the young animal with boiled or
pasteurized milk, and we should not lower food values by such methods.*

* It is now admitted that pasteurization and boiling kills "newly discovered vitamins" which are the "life elements" constantly referred to in my earlier writings.

I do not wish to intimate, however, that scrupulous care and cleanliness should not be exercised in the selection and handling of the milk.

Wherever possible, secure the milk of a single healthy cow that grazes on green pastures or is fed on normal clean food mixtures. Milk from cows kept in stables and fed on brewery and distillery slops and other refuse should not be used.

Every vessel and utensil with which the milk comes in contact must be carefully scoured, submerged in boiling water, drained and kept in a light, airy place.

The nursing bottle, after each feeding, must be taken apart and carefully scrubbed, inside and out, in hot water with an addition of a little soda. It should then be left in pure, cold water, until the next feeding time.

2. When to Feed. Physicians quite generally recommend feedings at stated hours, in fixed quantities.

This is altogether wrong, it establishes at once the stuffing habit, does not permit the development of natural desire and its regulation. The infant very soon becomes accustomed to eating at certain times, whether it really needs the food or not.

Food should not be given until there is an actual demand for it, which will express itself in real hunger. By careful observation and experiment the mother will soon learn to distinguish the ordinary crying of the baby and the desire for food expressed by it. If this practice of feeding only when there is a natural desire for food is strictly followed, the infant will soon establish its own regular feeding times, usually at intervals of about three or four hours in the daytime. The stomach digestion of a feeding of milk will require about three hours, therefore a minimum of that much time should be allowed between feedings after the first few weeks.

If the mother can nurse her baby, it should be put to the breast upon awakening from its first sleep, either before or after bathing and dressing.

The first secretion of the breasts (colostrum) is not really a food, but performs an important function in cleansing the intestinal tract and preparing the digestive system to properly digest and assimilate the milk when it comes, usually about the third day.

3. How to Feed. If artificial feeding must be resorted to, no food at all should be given, except a few teaspoonfuls of water, during the first twenty-four hours after birth. During
the next few days, cow's milk should be given, well diluted—about one-half milk and one-half filtered or boiled water. From week to week the amount of water should be reduced until at the end of the second month the baby takes cow's milk undiluted.

4. Night Feeding. In the nighttime feeding should not be encouraged. During the first four months it is advisable to feed not more than once during the night. After that the child should be weaned from the habit entirely. This will be facilitated by giving a drink of water instead of milk.

5. Amount of Food. Discretion should be observed in determining the amount of food. Do not induce the baby to take as much as possible, rather as little as possible. Its welfare does not depend upon the amount of food consumed, but upon the amount which it can easily digest and assimilate.

When more food is given than the digestive organs can take care of, the entire mass may ferment and sour.

6. Grain Extracts. If undiluted milk proves too rich, grain water may be added. In order to prepare this, take clean grain as it comes from the field, crush it in a hand grain mill or a new coffee mill, take three tablespoonfuls of the crushed grain to one pint of cold water, and boil on the stove for one hour; or in the fireless cooker for two or three hours, in which ease use a little more water at the start. While the gruel is boiling over the fire, add enough water to allow for evaporation and absorption. When thoroughly cooked, strain the gruel through a fine cloth or sieve. Add one tablespoonful, or more if necessary, to each milk feeding.

When baby is constipated, add to the milk, grain extract made from oats, and frequently cool the bowels with cold water. This will cure the most stubborn constipation. If the bowels are too loose, add to the milk, extract made from barley or wheat.

The small particles of hulls in the grain extracts improve digestion and evacuation, in a mechanical manner. They permeate the curds and keep them from coagulating too solidly, thereby facilitating the penetration of digestive juices; they also exert a mild stimulation on the walls of the intestines, thereby increasing the peristalsis of the bowels and evacuation of feces.

7. Baby's Natural Medicines. Fruit juices and scraped raw ripe pear or apple and the pulp of cooked fruits such as prunes or figs without addition of sugar or sweetening of any kind, are baby's finest medicines. They increase the supply of organic salts for blood, nerve and bone building and for purposes of elimination. They are nature's own chologogues, laxatives, tonics and antiseptics. They keep the little body sweet and wholesome. All babies under our care receive fruit juices beginning with the second week.
During the first two months, give one teaspoonful of orange juice, grape fruit juice or prune juice, one hour before or after each nursing. After the second month, gradually increase the amounts of fruit juices and begin to add raw pear or apple scraped with a spoon or dull knife, or the mashed pulp of fully ripened peach or grapes.

8. Weaning the Baby. Nursing infants should be weaned from the breast after the eighth or ninth month. From the sixth or seventh month, both nursing and bottle-fed babies should begin to take some solid food. The best of these to begin with are whole-grain cereals, gruels, raw and cooked fruits and tender vegetables in small amounts. Mealy baked potato is one of the best foods, better than the cereals.

9. Feeding After First Year. After the lapse of the first year, the solid foods are gradually increased and the milk reduced in quantity. Eggs should not be given before the eighteenth month, then soft-boiled or poached. During the second and third year half an egg twice or three times a week is sufficient; after that an egg at a time may be given once or twice a week.

Meat and all other foods prepared from the dead animal carcass are bad enough for adults, but it is inexcusable to give them to tender infants and children.

Dog fanciers, when they sell a valuable canine, usually advise the buyer not to give the animal any meat before the second year, lest it become a victim of distemper; and dogs are naturally meat eaters.

Well informed physicians now generally advise not to give meat to children before the fifth or sixth year. They have learned this much from the nature cure people.

Foods undoubtedly have a powerful influence, not only on the physical body, but also on the mentality and the emotions. These problems will be interesting subjects of investigation for the food chemist and psychologist of the future. In general, we may say that flesh foods are stimulating and feed the passional nature, while fruits and tender vegetables refine and stimulate brain and nerve matter as well as the intellectual, emotional and spiritual activities. Cereals, nuts and pulses build and repair the physical body and supply the body with heat and muscular energy.

The majority of animals adhere strictly to one kind of food, and therefore faithfully exhibit in their mental and emotional characteristics the effects of different food materials. Ferociousness we find personified in the carnivorous bulldog, lion, tiger and panther (that is why soldiers are fed on meat three times a day); glutony and omnivorous voraciousness in the hog, chicken and hyena; cold-blooded cunning in the fox, and cruelty in the cat. The intelligence of the carnivorous animals displays itself mainly in the cruel cunning with which they stalk their living prey. It resembles in quality the low
intelligence of the human criminal.

Personifications of great physical strength, intelligence, endurance, patience, gentleness, fidelity, affection and self-control, we find among the vegetarian animals. The beaver, the arboreal ape and the elephant are especially noted for their intelligence; deer, antelope and sheep for gentleness; the horse for its almost human intelligence, affection and fidelity; oxen, elephants and camels for their great strength and endurance.

Meat is detrimental to the child in every way, physically, mentally and morally. The poisonous acids and alkaloids which it contains clog the capillary circulation, causing anemia, coldness of the extremities and defective elimination through the skin. This results in congestion in the interior organs, high blood pressure in brain and heart, headaches, nervousness, irritability, tendency to fevers, inflammations and catarrhal conditions.

With the meat, the child often absorbs the eggs of worms, tubercular bacilli, and other parasites and disease germs. Certain forms of epilepsy, St. Vitus' dance and hysterical conditions are due to uric acid poisoning and to other pathogenic materials and ptomaines contained in flesh foods. Such patients, in times of crises, frequently emit pronounced odors of raw meat or uric acid. Strictly vegetarian diet, combined with other eliminative natural methods of treatment, cures the majority of these cases.

Most of these poisonous acids, alkaloids and ptomaines contained in the flesh of dead animals are powerful stimulants. I have frequently noticed that people who have abstained from meat for a long time, when they first partake of it again experience sensations and exhibit symptoms resembling those of alcoholic intoxication.

We have learned that these stimulating extractives of flesh foods chemically closely resemble caffeine, thein and nicotine. The use of one or more of these stimulants invariably creates a craving for the others. This explains why a heavy meat eater is usually a confirmed coffee drinker or inveterate smoker, and vice versa; and why we find it almost impossible to wean people from one of these stimulants as long as they persist in taking the others.

The legumes or pulses—peas, beans and lentils—are close seconds to meat in acid-producing qualities. Eggs contain considerable ready-made uric acid and a great deal of sulfur and phosphorus. These may become dangerous to the organism. For these reasons, meats, legumes and eggs are always danger foods for the child.

Children brought up on such foods will show the effects in nervousness, irritability, lack of self-control, craving for cigarettes and alcoholic stimulants. The most serious aspect of this question lies in the stimulative influence of meat poisons
on the sex centers. It is a well known fact, verified by close observation, that flesh foods stimulate the sexual passions to a marked degree. This tendency is greatly increased by the use of coffee, tea and alcoholic stimulants in the form of wines, liquors or medicines. If the sensitive nervous organism of a child is overwrought by these powerful irritants, there can be but one result; precocious sexual awakening.

From the third year the child may gradually adopt with slight appropriate modifications, a diet as outlined under Sec. I, No. 10, and Sec. X, No.7.

SECTION XL

Exercises in Infancy

1. Exercises in Infancy. Proper exercise is important from the very beginning of life. A baby will follow its natural instincts for exercise if allowed to do so, by working its arms and legs and writhing its little body in all directions, if not unduly hampered by tight clothing and bandages. A few nude air baths every day will afford excellent opportunity for baby's gymnastic stunts.

After he is a few months old he may be placed on his stomach, when he will exert himself vigorously by trying to raise his head, to turn around, or to raise himself with his arms. He will soon learn to roll over and to creep nay now be pulled up gently by his arms and lowered again a number of times in succession.

When three or four months old he may be lifted by one arm or by both arms; by the right arm and left leg, or by the left arm and right leg. When the baby is six or eight months old, he should be strong enough to rise from his back to a sitting position. This may be encouraged by holding down the feet. I have known a number of nature cure babies who at six months of age clung tightly to a stick while being lifted a few feet from the bed. Another good exercise greatly enjoyed by the youngsters is to roll them back and forth on a bed.

The average healthy child will secure ample exercise while learning to walk and run and while playing with simple toys or with other children; but this may be supplemented to good advantage by special exercises devised by the father and mother. Nothing is better for the health and happiness of both parents and children than to join in merry romp and play.

Between two and five years of age the child may be taught more difficult stunts, performed either by himself or with the assistance of the father or mother; but swinging the child high overhead, throwing him up and catching and other dangerous tricks should be avoided. They are risky and have very little effect in developing the body of the child. The best exercise at this age consists in outdoor play and games.
From the sixth year, the question of exercise becomes a more important one, especially since the children are confined for many hours in school rooms. If exercise at this time of life, through play and games and special gymnastics, is neglected, it may affect health, strength and efficiency of the child for life.

Those of good physique and ample strength may gradually take up and practice the exercises for adults outlined in sections XXI, XXII, XXIII, XXIV.

2. High Chair. A baby should not be put in a high chair until he is quite well able to hold the spine and head erect, and should never be left in a chair for any length of time. If a baby is forced to maintain a rigid, sitting position for a considerable time, before the bones and muscles are sufficiently developed, this may produce deformity of the spine. Maids and nurses, if not properly supervised, sometimes fasten a baby in a high chair and leave him there to take care of himself for long periods.

3. Toys. Since most babies have a habit of putting everything into their mouths, toys must be selected that can do no harm. They should have no paint, no sharp points or corners which might hurt the eyes or mouth, and must be of material which can be easily and thoroughly cleansed. Hairy and woolly playthings are unsafe, being unclean and germ carriers. Objects small enough to be swallowed must never be put within baby's reach. The simpler the playthings the better; a few clothespins, empty spools, or other simple objects are better than expensive toys.

SECTION XLI

Baby's Ailments

1. Hernia. As a result of a weakly or sickly condition of the mother during pregnancy and of faulty prenatal management, many children are born ruptured. So far I have not known a single nature cure baby that was born ruptured. Such defects are due to weakness of the tissues. This results from mineral starvation. The tissue walls contain too much mortar (protein) and not enough building stone (mineral salts). Prevention of hernia, therefore, lies mainly in proper diet of the pregnant mother, but all the rest of the prenatal regimen described in these pages is of great importance in preventing this and other ailments and deformities.

There are three principal points at which rupture or hernia may take place in infancy—at the navel, in the groin, and at the line between the navel and the lower end of the sternum. Other kinds of ruptures are extremely rare.
2. **Umbilical Hernia** This is a protrusion of the intestine at the navel. It is the most common rupture in infancy. Pulling on the cord during childbirth, urging at stool or violent crying may result in rupture. The umbilical ring first expands and this forms a pouch into which one of the folds of the small intestine protrudes.

Treatment: Of primary importance is the diet as outlined herein. The baby must have plenty of fruit juices in order to reinforce the mineral salts in the milk. Cold bathing is very beneficial. The rupture itself should be cleansed several times a day with warm water. This must be followed by a wash with cold water mixed with lemon juice. Gentle, passive exercise, such as raising, lowering and twisting the limbs from side to side, also raising and lowering the body while supporting the shoulders and head, is of especial value.

The rupture must be reduced and kept from protruding by placing over it a large button or other article of similar shape, wrapped in gauze and held in place by broad strips of adhesive plaster. The adhesive tape is fastened over the button crosswise and must be applied in such a manner as to draw the skin from all sides over the rupture. Instead of the button, a compress made of gauze may be laid over the rupture and held in place by one broad adhesive strip. The covering of the rupture must be removed and renewed every day in order to allow cleansing, as before described.

When the child is old enough to exercise by himself, he should be taught special movements of the body and the limbs which develop the muscles of the abdominal region.

3. **Ventral Hernia.** This occurs along the middle line of the body between the navel and the breastbone, sometimes below the navel. The rupture may not be larger than the size of a pea or small marble, and may disappear on pressure. The treatment is the same as that of umbilical hernia.

4. **Inguinal and Scrotal Hernia** occur in infancy or in adult life; sometimes the inguinal canal does not close after the descent of the testes from the abdominal cavity into the scrotum, and the intestine descends through the open canal, thus producing the rupture. These forms of hernia become aggravated by coughing. They can be reduced immediately with gentle manipulation while the patient is lying on his back. This kind of rupture may be distinguished from hydrocele by the fact that in reducing it goes back easily with a gurgling sound. Hydrocele is not affected by coughing. A hernia is opaque to transmitted light; hydrocele, transparent.

These ruptures should be protected with a well-fitting truss. This has to be removed daily for cleansing of the parts. Appropriate exercises, passive and active, together with cooling sitz baths and washes with cold water and lemon juice are the best remedies for these, as well as of other forms of rupture.
5. **Congenital Hernia** occurs in the form of inguinal hernia and has to be treated in the same way. Ruptures of any kind must be reduced and properly supported. Constipation and consequent urging at stool may cause or aggravate any form of hernia and must, therefore, be overcome by the right treatment described under section XXVI, No.1.

6. **Colic.** This is usually caused by indigestion due to overfeeding, improper feeding, or too frequent feeding. The intestines are distended with gas, giving rise to a severe pain. The baby cries sharply, alternately drawing its legs up to the body and kicking them away. One of the quickest means of relief is a small enema of warm water and gentle circular massage of the abdomen from right to left. Food should be withheld until the symptoms have disappeared. The giving of milk or other food may quiet the attack temporarily, but the pain is apt to return with greater intensity. Warm water may be given if the baby will swallow it.

A baby managed in the natural way prenatally and postnatally is not likely to suffer from this ailment. Constipated babies are more prone to it than others.

Colic may also be caused by sudden chilling. In that case a warm bath for five or ten minutes, followed by gentle body massage will bring about a warm reaction.

7. **Convulsions.** These cause a great deal of anxiety to the fond mother. They are always reflex symptoms of some slight or serious internal disturbance due to wrong management. They commonly result from some form of auto-intoxication caused by digestive disturbances, and the resulting systemic or drug poisoning. An inactive condition of the skin, bowels or kidneys will favor auto-intoxication and convulsions. If proper care is taken to keep the system pure, and the organs of elimination in active condition, convulsions will not occur.

The best treatment during an attack is a quick, cold rub all over the body; application of a whole body or trunk pack; gentle soothing magnetic massage, and neurotherapy treatment. These treatments draw the blood into the surface and relieve congestion in the brain and nervous system.

8. **Ailments of Teething.** Many ailments of children are laid to teething, but this is a mistake. Well managed, healthy babies go through the teething period without any trouble whatsoever. This is practically always true of nature cure babies. When, however, the little body is heavily encumbered with hereditary and acquired morbid materials, food poisons and disease taints, the process of teething will not run its natural course and may precipitate any form of disease crisis.

When teething is difficult, it is frequently associated with digestive disturbances. Diarrhea may alternate with constipation and vomiting is of common occurrence. The baby may be restless and fretful. He tries continually to bite on something in order to facilitate the projection of the teeth.
through the hardened gums.

No teething lotions or soothing medicines of any kind should be given for the relief of pain in teething. They all contain poisonous sedatives which benumb and paralyze the nerves and have serious after effects upon the system. They usually contain opium in some form, or other narcotic drugs.

The only way to prevent these and other infantile ailments is to keep the little body as nearly normal as possible through the natural treatment described in these pages. If this is closely adhered to, it will prevent, in many cases, the development of even measles and other common eliminative infantile ailments.

During this critical period in the baby's life the diet must be extra light; starchy food should be reduced to a minimum and replaced by raw and cooked fruits and vegetables juices. Cooling sitz baths will help to keep the bowels active and to abate internal fever.

9. Acute Catarrhal Disease. Acute catarrhal diseases of infancy such as croup, cold in the head, acute bronchitis and whooping cough, are different forms of acute elimination through which Nature tries to purify the little body from hereditary and acquired accumulations of morbid matter, systemic poisons and disease taints.

In accordance with this conception of acute diseases, as purifying, healing efforts of Nature, we would not do anything to check or suppress elimination but cooperate with Nature in her purifying, healing efforts. How we do this has been fully explained in other parts of this volume. (Section VIII)

The natural treatment is very much the same in all acute inflammatory ailments. Feeding must be reduced to a minimum. If the baby does not insist upon eating, nothing should be given except water with acid or sub-acid fruit juices, such as lime, lemon, grape fruit and orange. If the temperature does not run high, say not above 100 or 102 deg, frequent ablutions with cold water at intervals of from one to two hours will be sufficient to promote heat radiation and elimination of morbid matter through the skin and other organs of elimination. If the temperature runs' higher, say between 102 and 105 deg, wet packs must be applied, and renewed when they become hot or dry.

The wet packs are of especial value in all kinds of cough; whether it be the ordinary cough, croupy cough or whooping cough. A whole body or trunk pack, with or without a throat pack, will give almost instant relief. In many instances where baby is making the night hideous for the anxious mother, with it's coughing, a well-applied whole body pack, or a combination trunk and throat pack, will relieve the coughing almost instantly, and induce restful sleep.
In serious cases it is always advisable to call in a natural therapist or some other drugless physician, if one can be reached.

The mother should not forget that all acute diseases, after they have once developed, must run their natural course. She must, therefore, not become impatient and lose faith in the natural treatment if it takes a week or more to cure a common cold in the head or an attack of bronchitis, or if it takes from two to eight weeks to cure a case of whooping cough. Serenity, patience and cheerfulness are the primary requisites of the nature cure physician.
PART IV

BABY BOOK

Natural Therapeutics has undoubtedly solved the problem of treating human ailments. All other schools and systems will in time have to adopt the natural way. It is the hub of the healing art; all therapeutic methods radiate from it like spokes from a wheel.

Natural Therapeutics, however, has something better to give than treatment of disease, and that is prevention of disease. If children were brought into this world in the manner ordained by Nature and reared in harmony with the teachings of natural philosophy, disease would soon be a thing of the past. Human beings would then enjoy good health and be as beautiful and perfect in their kind as are animals, which live in the freedom of Nature, guided by instinct and therefore in harmony with the laws of their being.

We must begin, then, with prevention, for prevention is always easier and cheaper, than cure. But where must we begin to study the prevention of disease? Some will say, "At birth, because that is the beginning of life." Not so: that would be too late. The mould is made and the foundation laid for health or disease, for happiness or suffering, for efficiency or deficiency, before the human being in process of creation sees the light of day.

"Then," it may be said, "we must begin with prenatal influence, for the physical, mental, emotional and moral habits of the mother influence powerfully the development of the new life she is carrying." True—but we must start earlier than that. The making of the human being begins with mating and conception. All subsequent development depends upon the right start.

SECTION XXXII

Heredity

1. Importance of Correct Mating. Of primary importance in the sacred rite of procreation, as already intimated, is mating. This should take place only between descendants of the same subrace, or of closely related subraces such as the Indo-Caucasian and Celtic.

If the racial descent of the marriage partners is so far removed that it has produced pronounced differences in racial
characteristic—as in the case of the swarthy Mexican and white skinned Englishwoman, or the dark eyed Magyar and blue-eyed Scandinavian—then procreation becomes miscegenation and degenerates into mongrelization of the offspring. Everywhere in the animal and human kingdoms Nature has set the mark of disapproval on the mongrel. The offspring of miscegenation is doomed to deterioration and extinction unless assimilation of the elements of a lower race by a higher takes place sparingly and gradually.

The law of racial purity may be summed up as follows: When a member of a higher race cohabits with a descendant of a lower race, the offspring of the union loses more or less the characteristics of the higher race and reverts in physical, mental and moral traits to the level of the lower race.

The constructive results of racial purity are evident in Hindus of the higher castes; in that portion of the Jewish race which in mating has faithfully adhered to the Law of Moses, and in the blond and blue-eyed remnants of the Indo-Caucasian and Celtic races in Northern Europe and North America. The destructive results of miscegenation are plainly evident in the mongrelized population of Mexico and everywhere in the half-breed and many kinds of mixed breeds. These usually fall below the physical, mental and moral standards of the parent stock, and almost invariably revert to the customs and habits of the inferior race.

2. Use Heredity. Use heredity deals with the transmission to offspring of acquired physical, mental and moral characteristics of the parents. According to this law as it has been formulated, the chances of the offspring for long life, health, mental efficiency and moral stamina, other conditions being favorable, are better in direct ratio to the advancing age of the parents at the time of conception. While this is contrary to popular opinion, which assumes that younger parents produce more perfect offspring than older ones, the fact of use heredity is proved, both in the animal and human kingdom, by common observation and statistical evidence.

The working of the law is based on the fact that the procreative elements of the parents, or rather the microzyma of those elements, cannot contain the impress of physical, mental and psychical characteristics which at the time of procreation were not developed in the threefold organisms of father and mother.

The age of the father at conception is called the "birth age" of the offspring and determines its birth rank. While the father and previous male ancestors, for reasons hereafter explained, seem to exert greater control over the mental and physical characteristics, the mother furnishes the nutrient soil for physical growth. This does not mean that she exerts no control over the mental and psychical characteristics of the offspring; in addition to her influence through use heredity she has added opportunities through prenatal influence and postnatal training.
According to this law, then, the chances of the offspring for excellent physical, mental and moral development become better as the age of the father at the time of procreation advances beyond thirty five; while the physical condition of the mother for reproductive function is best below thirty five years.

But we must not overlook the fact that too great a discrepancy of age between the man and woman may become the cause of physical and mental incompatibility, of aversion and great unhappiness, especially on the part of the younger woman.

Extensive statistical evidence seems to prove that the birth age of the mother has been of less importance than that of the father. As will be shown in Natural Eugenics, the majority of famous men in all lines or human endeavor had old male ancestors, while the mothers and previous female ancestors were of much younger age at the time of conception.

This may be accounted for by the following reasons:

The man is usually considerably older than the woman at the time of marriage. Men, as a rule, devote much more time and effort to acquiring a scientific, professional or business education than do women. This has been true in the past more than it will be in the future. Thrown early into the competitive struggle of life men generally have had to make greater mental and physical effort than have women.

These points are of considerable importance because it has been proved that it is not inherited brain mass and mental capacity, but strenuous and persistent effort that intensifies use heredity. The earlier this begins and the longer it continues before procreation takes place, the better the chances of the offspring for physical, mental and moral capacity.

The reproductivity of the mother has usually ceased at thirty-five. Though she be capable of childbearing a few years longer, usually conception has been avoided after that age. Men under favorable conditions remain reproductive to advanced age. Some of the world's greatest men descended from fathers over sixty years old.

That intellectual and creative capacity has followed the male line of descent rather than the female line, is indicated by the fact that the high intellectual capacity of many eminent men has skipped their daughters to reappear in male descendants. This may be partly accounted for by the fact that the daughters in their limited spheres of activity have not had the opportunity to unfold inherent intellectual capacity to any conspicuous degree.

There has been a tendency in some quarters to criticize the general entrance of women into professional and commercial life and to dilate upon the adverse influence this will have
upon womanly characteristics and family life.

In the light of the knowledge we possess upon the subject of use heredity, it is safe to say that any such problematical drawbacks will be far outweighed by the general postponement of the marriage age. This will insure not only better physical fitness but also higher intellectual development and greater moral stamina on both sides of parentage.

The tremendous benefits which this increased hereditary endowment will confer upon future generations cannot be overestimated. Greater intellectual and economic equality between the sexes will emancipate woman from degrading sexual subservience. Under the old order, sex appeal was too often her only stock in trade by which to attract and hold the male and thus to secure a living. Economic independence will insure greater consideration and higher esteem for the woman on the part of the man. It will go a long ways toward solving the problem of birth control in a natural way, by leaving it more largely to the judgment of the mother.

We find the law of use heredity according to birth age verified in the intelligence and moral development or obliquity of races, nations and tribes all over the earth—The lower the average birth age of a race or nation, the lower, other things being equal, the intellectual and moral development. The greatest development and efficiency is found among those nations where marriage is delayed to a later age through custom, economic necessity, professional or military training.

The following quotation from "Control of Heredity", by Casper Lavater Redfield, is of interest in this connection:

"In general it may be said that wherever there are no restraints upon the sexual propensities, as with the Digger Indians, the Fuegians, the Andamanese, the Wauraus of the Guianas, the Bushmen and the tribes along the Gabbon river, there we find reproduction taking place at the earliest possible age, and the lowest grade of intelligence. Where we find some special circumstances or customs that delay the age at which reproduction takes place, as with the Patagonians, the North American Indian and the Polynesians, there we find considerably higher grade of intelligence.

"Where we find the custom of marrying late in life, as was customary with the Greeks and the Romans, there we find a very high grade of intelligence. And where we find a fortuitous succession of very late births, there we find the very great men of the world's history.

"In other words, the longer the time in which the individuals have in which to use, develop and strengthen their brains before reproduction begins, the greater and more powerful are the brains of their descendants."

In Volume IV of this Series I shall quote elaborate and
highly interesting statistics from Redfield, which reveal the effects of the various birth ages on physical, mental and moral characteristics. I shall confine myself, for the present, to the statement that, with few exceptions, the great artists, scientists, philosophers, statesmen and philanthropists were born from fathers whose ages ranged from forty to sixty-five years at the time of the procreation of their famous offspring.

The existence of these laws and principles as facts in nature is very evident in the training of racehorses and of other animals along certain lines of proficiency.

3. Pernicious Heredity. The effects of deteriorating and destructive heredity prenatal and congenital influences have been traced and commented upon in so many different ways that I do not believe it necessary to enter deeply into this phase of the subject. Various authors have filled entire volumes with the unsavory family histories of the descendants of the Jutes, Ishmaels and other drunkards, prostitutes, degenerates and criminals, which prove positively the transmission of morbid and pernicious traits through successive generations. It has been proved statistically beyond the shadow of a doubt that youthful delinquency, pauperism and criminality are the aftermath of immature marriages.

The laws of use heredity and prenatal influence, like all other natural laws and principles, manifest along opposite lines of expression. It remains for us to determine whether we shall align ourselves with their destructive or constructive activities. The effects upon ourselves and our offspring will show accordingly.

If I succeed in arousing the consciousness of prospective fathers and mothers to the glorious privileges and enormous responsibilities which these laws of nature confer upon them, then my labor will not have been in vain and I shall feel deeply gratified.

SECTION XXXIII

1. The Creative Alchemy of Love and Affection

Procreation—as is the case with everything else pertaining to the constituents and functions of the human entity—takes place on three planes of being, the material (physical and spiritual), the mental and the psychical planes. Which of these elements shall predominate in the offspring depends upon the mixture and adjustment of qualities in the triune makeup of the mating couple. In order to fulfill the law and to draw the divine blessing upon themselves and the fruit of their union the partners in the procreative function must be united by the bonds of love, or at least by the ties of true affection.
The source of creative genius is love and wisdom, and the essence of intelligence and power is sincerity and goodness. Without these, intelligence degenerates into selfish cunning, power into self-destructive brute force. The spring cannot rise higher than its source; its water cannot be pure and wholesome when contaminated by impure admixtures from filthy surroundings.

It is not generally known that use heredity pertains to intellectual and psychical qualities, as well as to the physical material. Animalism breeds nothing but selfish animalism. The vampire who craves and absorbs the love of its victims and robs them of vital energy, without being capable of feeling or bestowing affection, is the child of a discordant union—of brute animalism on the part of the man, of secret aversion and hatred, usually, on the part of the woman. These bestial and degrading tendencies on the one side, and unrequited love craving on the other, breed sex perversion, and propagate the harpies who delight in the seductive power of superficial beauty, while gloating over the weakness and ruin of their victims.

True love and affection, paired with intelligence and goodness; liberate the creative elements necessary to the production of perfect offspring.

The finer qualities of mind and soul open the fountains of life on the higher planes, liberate and harmonize the male and female procreative fluids, and charge them with the purest and most potent intellectual, spiritual and psychical elements.

The divine fire of creative genius burns only in the love aura of truly mated couples. It is true that these are rare under our artificial, unrighteous social institutions, and that accounts for the rarity of complete manhood and womanhood.

Perfect offspring, endowed with beauty and power of body, mind and soul, destined to shed through life a radiance of health, happiness and helpfulness—to love and be loved—issues only from the union of love and affection with intelligence and goodness.

"Love lieth at the foundation" (of all that is). "Love is passion, enthusiasm, affection, heat, fire, soul—God."

To the extent that love enters into the holy rite, to that extent its attributes will be absorbed in the threefold organism of the woman and become active in the child building in her womb. While she loves her man more than ever, her most passionate affection is centered in the new being in process of development. On it she bestows the purest and best in her food and drink, in her thoughts, emotions and secret desires. Fear, worry, anxiety, jealousy and hatred are strangers to her soul; these are the emanations of the lower spheres—she lives in heaven.

Somebody endowed with deep insight into these matters has
"Whatever male and female shall truly will for, hopefully pray for and earnestly yearn for, when love pure and holy is the nuptive ascendant, in form, passionate, affectional, divine and volitional, that prayer shall be granted, and the boon be given—but the prayer must precede."

What are the direct effects of the marital rite upon the participants? If the sex attraction operates on the physical material plane only, if lust instead of love presides at the matrimonial feast, then temporary gratification of erotic craving will be followed inevitably by monotony, satiety, gradual revulsion and aversion, culminating in a morbid craving for change and variety. The partners in carnal self-indulgence are intuitively aware of these tendencies to marital unfaithfulness, and, therefore, easily dominated by distrust and jealousy.

The procreative function is attended by complete satisfaction, buoyancy of body and mind and lasting happiness only when sex attraction operates on the higher and highest planes of being, as well as on the lower, when desire and impulse are operative on both sides. Thus only will the generative function fulfill its sacred purpose and confer the highest possible benefits upon parents and offspring.

The woman, being the more highly sensitized, must be responsive to the call of holy passion. To force unwilling compliance will ruin the woman, kill her love and curse her offspring. Balzac says: "He who begins with his wife by a rape is a lost man." It is impossible for a wife to love unless she is won, not forced to compliance.

2. Sexual Intercourse During Pregnancy. Sexual intercourse should be considered the most sacred function of the human entity. From the highest and best viewpoint it should be exercised only for the propagation of offspring. However, considering the present stage of ethical and moral development, temperate indulgence may not be wholly condemned. Excessive intercourse is always weakening and harmful to both participants. We must remember that the sex fluid is the carrier of the life force. It is that which constitutes strength, resistance to disease, initiative and genius. During abstinence from intercourse the sex fluids with their creative energy are absorbed through the inguinal glands into the organism and increase physical, mental, moral and spiritual capacity and energy.

Set rules for frequency of intercourse cannot be given. This must depend entirely upon individual conditions. One safe rule is that after indulgence there should be no feeling of satiety, weakness and exhaustion. The more frequent the indulgence the stronger will grow the power of habit and of passion and the greater will become the abnormal craving. It is the same with all other appetite and passions. The more frequently they are indulged, the stronger they grow, until
they attain complete control and develop into destructive habit

A free and confidential understanding in regard to these matters between those who contemplate matrimony would go far to prevent marital misery. A great deal of unhappiness arises from the fact that mates in the matrimonial union often labor under misapprehensions concerning the attitude of each toward the sex relation, and are prevented by excessive sensitiveness and delicacy from frankly discussing it. (For further discussion of this subject, see page 390, Volume I.)

There is no problem of married life that needs more thorough mutual consideration and understanding than this one. Lack of it accounts for a great deal of "incompatibility," loss of love, revulsion, hatred, and the final tragedy in the divorce court.

Among animals, no female allows intercourse after conception. In this respect as in many others, man has sunk below the natural standards of the animals. No greater crime can be committed against the woman and the unborn life.

It is a sad commentary on our system of education, scholastic as well as religious, that our young people are not instructed before and after marriage in these all important laws of Nature. To do this should be the province of the priest who unites them in marriage, or of the family physician, if the parents have failed in their duty.

It is well known (notwithstanding the denials of medical skeptics) that the unborn infant may be "marked" by transitory impressions, especially by strong emotions; that even insignificant parental characteristics are reproduced in the offspring. Is it any wonder, then, that the most powerful of human emotions should leave its impress on the growing brain and sex centers of the fetus, causing abnormal and precocious sex consciousness?

All too often is sex perversion born and bred in bone and flesh, before the child sees the light of day. The mother cannot be blamed for this "slaughter of the innocents"; she has not been instructed on the subject. Though she intuitively senses the horror of it, she submits, in order to maintain her hold upon the man—and many a life is thus cursed before it is born. The fault lies primarily with those of the medical profession who teach our young men that the free indulgence of sexual passion is not only legitimate, but a necessity to manly vigor.

This dictum of pseudo-science is almost universally concurred in by spiritual guardians. **No greater lie was ever promulgated from the blackest abyss of Hades.** If our young men were taught that greater happiness is to be attained by the exchange of tender affection than by the indulgence of the coarser animal appetites, that the creative forces thus preserved develop and strengthen their own finest capacities.
of body, mind or soul, they would wisely and chivalrously protect mother and child, at the same time conserving their own physical and moral integrity.

In no other way is it possible to call forth the deepest gratitude and unfailing esteem of a true woman. Many a man whom we have thus advised has become a lifelong friend in consequence.

3. Limitation of Offspring. I believe that the unlimited production of offspring, encouraged in some quarters for swelling the ranks of religious bodies or for increasing tax paying and cannon-fodder material, is a misfortune, both to the family and to society. Limitation of offspring, in accordance with the means and circumstances of the parents, is not only justified but should be encouraged. In any case, the production of offspring entails great responsibility upon the parents and if they cannot properly comply with the needs and rights of their children, they fail in their responsibility and duty.

Any method, however, which interrupts intercourse or prevents conception in an artificial way, is absolutely to be condemned, because this has very harmful and positively destructive effects upon the physical, nervous and mental organism of those who thus try to cheat nature by the suppression of a natural process. In our professional work we frequently meet the victims of such pernicious practices. The ordinary contrivances for prevention make of intercourse something akin to masturbation. This is also true of intercourse without orgasm which is strongly advocated under various guises. The use of poisonous antiseptics and germ killers in warm water douches is not essential for prevention, and is highly injurious. These chemicals have a tendency to poison the sexual organs and to produce in time atrophy, many kinds of female disorders, and tumors. Undoubtedly the greater number of so called female troubles and malignant tumors in later life are caused by curetments, antiseptic douches and the use of poisonous drugs, for producing abortion. The only legitimate methods of birth control are abstinence or common cleanliness.

There is nothing more conducive to the physical, mental and spiritual health and development of a woman than childbearing and child rearing in harmony with Nature's laws, as outlined in these volumes. Under favorable conditions it is not a thing to be dreaded, but to be looked upon as the greatest of blessings and opportunities in the life of a woman. Natural philosophy and practice takes these problems of progeneration, childbearing and childrearing out of the domain of uncertainty and haphazard management with its dire consequences, and makes eugenics the most exact of all sciences and the sublimest and most enjoyable of all the arts.

4. Determination of Sex. Numerous theories have been advanced concerning this interesting subject. Many attempts have been made to wrest from Nature the secret of sex
determination and numerous more or less ingenious methods have been recommended for sex control.

I know of one method only which seems to have a rational basis and which has proved of practical value. Observations seem to prove that the right ovary liberates male ova only, while the left ovary discharges female ova. The two ovaries discharge ova only at alternate menstruations.

With this data at hand, it is possible to determine the sex of a child after one birth has taken place. Suppose the first child was a boy. By consulting our pregnancy table (page 377) we can determine when the last menstrual discharge took place. This menstruation liberated a male ovum; the next menstruation would liberate a female ovum, the next a male, etc.

Thus, using the last menstruation period before the last conception as a fixed point, it would be possible, figuring from period to period, to determine the sex nature of the ovum to be discharged at each following menstrual period. Account is taken of all regular periods during the time menstruation is suspended in pregnancy. Thus, conception may be timed in such a way as to impregnate at will a male or female ovum.

This solves in a simple, rational manner another of Nature's riddles, namely, the reason for the practically equal division of the sexes.

SECTION XXXIV

Prenatal Influence

There exists just as much diversity of opinion among scientists concerning the reality of prenatal influence as about race heredity, use heredity, disease heredity and many other mooted problems of science and philosophy, which we shall study in Vol. IV of this series. In the following I shall present and examine impartially the various theories and opinions concerning prenatal influence; then we shall be better prepared to draw our own conclusions.

1. Medical Science Denies Prenatal Influence. Medical men, as usual cocksure of the correctness of their theories and hypotheses based on the "latest discoveries", deny and ridicule the possibility of prenatal influence, and relegate it to the rubbish heap of popular superstitions. They base their judgment on the fact that no nerves pass from the body of the mother through the umbilical cord into the growing fetus in the placenta, which forms the soft protecting nest of the new life within the womb. They claim that since no direct nerve connection exists between the two, mental and emotional vibrations cannot be transmitted from the brain of the mother to the brain and nervous organism of the fetus.
Are there no other means of communication between the mind of the mother and the brain of the unborn!

In the volume dealing with Eugenics we shall learn how universal intelligence and creative will become individual intelligence and personal will.

Cosmic vibrations do not flow into the gray matter of the human brain over coarse physical nerve tracts. They come over the psychical wireless which connects the human soul with the world Soul, the individual intelligence with the universal or cosmic intelligence the human will with the divine will.

Since, as proved by modern brain and nerve anatomy, immaterial cosmic intelligence and "power to will" fashion the brain of the mother into physical material centers for the expression of human intellectual faculties, capacities and powers, why cannot these cosmic vibrations act in like manner over the psychic wireless through the soul and mind of the mother on the brain and nervous system of the fetal organism?*

These epoch making discoveries and revelations of modern brain anatomy are explained in Vol. IV of this Series, *Natural Eugenics—Man Building on the Physical, Mental and Moral Planes.*

Why should the wireless, which transmits impulses of intuitive intelligence from the great source of all intelligence and creative energy into the soul of the mother, cease to operate at that point, and fail to transmit its message to the brain and nervous system of the fetus which is most intimately related and connected with the organism of the mother?

What about the phenomena of hypnotism? Absolute control of the subject's mind, through the intelligence and will of the hypnotist does not depend upon the existence of an umbilical cord and physical nerve connection between the two. The hypnotist, by silent command, may call his subject from a distance, far beyond the reach of his voice.

People telepathically attuned may communicate in like manner, spontaneously, or by conscious intent. Why then should we doubt the possibility of vibratory correspondence between the mental and emotional conditions of the mother and the plastic nervous organism in process of development within her womb?

If a complexity of sound can impress itself permanently upon the wax cylinder of a phonograph, or what is still more marvelous, if the photographic rays of passing scenes can be fixed and retained in the picture film, why should it be impossible for the mental and emotional vibrations of the mother to impress and modulate the molecular and cellular constituents of the fetal brain and nervous organism?
I have compared this creative power of the mother mind to the process of electrotyping. As the particles of metal in suspension in the fluid adhere to the spoon that is to be coated with silver, so the atoms and molecules in the gray matter of the brain of the fetus group themselves in harmony with the thought forms and emotional vibrations of the mind and soul of the mother. While this mental and psychical electrotyping takes place automatically, the mother's brain and nerve molding power can be greatly strengthened and intensified by the conscious and voluntary operation of the psychical wireless that establishes vibratory oneness between her and the human entity in process of development within her own body.

Thus it is revealed how a brain prenatally refined, organized and fashioned may endow the nascent individuality with certain aptitudes and talents along established paths of cerebration. There surely will be less resistance along such lines of physical, mental and moral endeavor than along other lines not prenatally influenced and molded. Therefore I strongly advise mothers, pregnant with new life holding marvelous possibilities for good or evil, not to be influenced by the superficial reasoning of materialistic science, but to follow the sacred intuition and impulse of their own creative genius in this, the most holy function of their being. Every normally constituted mother intuitively aware of this wonderful power, and is willing and anxious to exercise it when her consciousness has been aroused to the great possibilities and responsibilities which the divine privilege of motherhood confers upon her.

It is natural for us to admire a great artist who portrays the human form, true to life, on the painted canvas, or who fashions it from inanimate stone, metal or marble; how much more grand and godlike is the creative power of truly mated parents whose privilege it is to bring into the world, and to fashion according to their highest ideals, a human being endowed with life and intelligence, with the infinite possibilities of a new center of creative activity.

Yet many mothers, totally ignorant of their divine creative privileges and possibilities, victims of physically and morally degrading marriage relations, and often filled with secret aversion or open hatred for their marital companions, pass unwillingly through pregnancy and not infrequently seek to destroy the new life. When the unfortunate victim of such marital incompatibility, conceived in passion and developing under the worst possible influences of mental and emotional discord, comes to arouse the maternal instincts of affection and devotion, then fear, anxiety and worry, like a continual nightmare, haunt the unhappy mind of the mother and impress their discordant vibrations upon the sensitive films of infant consciousness.

Compare this condition of fear, apprehension and gloom in the mind and soul of an unhappy and unwilling mother, with the joyful and ecstatic state of mind of a mother conscious of
the creative power of her intelligent will, who, from the time of mating and procreation, with accurate prescience prepares the most favorable conditions, astrologically, prenatally and postnatally for the finest development of the physical, mental and moral characteristics of the future world citizen.

The loftiest exaltation of a creative genius working in dead clay and cold marble cannot approach the ecstasy of a mother who has acquired a knowledge of the great laws which make possible the development of a perfect human being, the embryo of a master, an angel, a being destined to be godlike in its faculties, capacities and powers!

In place of fear and anguish of soul, what joy to the mother who knows that it lies within her power to prevent disease and degeneracy in her offspring; that the development of the child depends solely upon her own intelligent effort! Nothing is left to accident. Child bearing becomes an exact science, the most beautiful and inspiring of all arts and professions. Under such conditions motherhood, instead of being the greatest of hazards and hardships, becomes a divine privilege and the highest achievement of human existence and endeavor. It falls short only of the creative work of the great Universal Intelligence whose instrument of creation is the mother.

2. An Example from History. Let us consider the oft-quoted example of Napoleon Bonaparte. His mother, Lutitia Bonaparte, while pregnant with the future military genius, accompanied her husband on a military expedition, sharing with him the hardships and excitement of camp life, and the marches and battles of a military campaign. If there be nothing in prenatal influence, is it not singular that Napoleon should have become one of the greatest military geniuses of all ages, while not one of his many brothers ever exhibited enough military ability to make an efficient corporal? What was it that favored or determined the birth of the great military prodigy under these circumstances? The ancestors of Napoleon's father were not professional soldiers, nor was the father especially interested in military matters before the conception of his gifted offspring.

The dominant influences, therefore, must have operated through the singular occupation and surroundings of the mother during this particular pregnancy.

Many similar striking examples have been cited in works on prenatal influence. I myself might add many convincing proofs from an extensive experience in medical practice; but time and space do not permit. Contributory evidence may be secured from many excellent works dealing with this vital problem in human life. I may be permitted to say that use heredity and prenatal influence are distinctly manifest in the physical and mental characteristics of our three children who were born at intervals of seven and five years. Each one of them clearly mirrors in his or her physical, mental and emotional peculiarities the predominant mental tendencies, occupation and surroundings of the parents during the
respective prenatal periods. Similar manifestations of prenatal influence may be observed in almost any family.

3. **Birthmarks.** Medical men of late deny also the possibility of "marking" the offspring by sudden fear or shock on the part of the mother during pregnancy. Incidents of this kind, however, are of such common occurrence that it is a waste of time to refute these flippant denials.

There are good reasons for believing that such marking is more likely to occur during the periods when the menstrual flow should take place, but is suspended.

It may be argued that to mention the possibility of marking to a pregnant woman will greatly increase the probability of electrotyping violent emotions upon her offspring; in other words, that the fear of the thing will help to materialize it. This may be true to a certain extent, but we must remember that sudden shock through fear or disgust may cause the mischief anyway, whether or not the expectant mother is aware of the possibility. Understanding a danger and being prepared for it seems the best protection. The pregnant woman should study carefully section XXX, dealing with mental and emotional causes of nervous diseases, and should learn to relax to any sudden surprise and thus neutralize unpleasant and fear arousing impressions. Self-control is the royal remedy and the key to mastership.

4. **Physical Influence.** Now that we have studied some of the more important hereditary mental and psychical prenatal and postnatal influences, let us see how the physical condition of the mother's organism influences the brain and nerve matter of the fetus in its last stages of development, and after birth.

Materialistic science teaches that brain matter exudes thoughts and feelings, as the liver excretes bile, or the stomach pepsin. Natural science proves that mind is superior to matter, that the new born ego, by the power of intelligent volition, must fashion in the gray matter of the brain the molecular groupings or centers for the expression of intellectual and emotional activities, such as language, music, numbers, scientific and philosophic speculation.

This means that active cerebration and brain molding do not begin until after birth. But it stands to reason that the work of the nascent intelligence may be greatly facilitated or impeded by the physical condition of the brain. It is reasonable to assume that intellectual and emotional vibrations will more easily shape the gray matter of the brain into new configurations when it has been prenatally refined, organized and developed along certain lines of cerebration by use heredity and by constructive prenatal influences.

There exists a remarkable similarity between the brain molding and memory building activities of the intelligent ego and the making of phonographic records and moving picture
films. Lifelike impressions of sounds and passing scenes can be made upon the phonographic and photographic mediums only when wax and film are in a highly refined and plastic condition. When impure of substance and coarse of texture they, are not sensitive and plastic enough to register and retain the subtle and highly complex vibrations of sounds and passing scenes. In order to receive and register a great variety and complexity of sounds, the wax on the phonograph cylinder must possess a certain degree of refinement, softness and plasticity. If it is too hard and coarse it registers the loud and coarse sounds only. Such a record cylinder, exposed to a beautiful symphony executed by a great orchestra, would register and reproduce only the shrill cries of the trumpet, the rattle of the snare drum and the booming of the big horns and bass drums. The softer sounds of string, wood and wind instruments and finer shadings of tone and rhythm would be lost. With increasing refinement and plasticity, more subtle and delicate sound vibrations will be retained and reproduced.

In like manner the sensitive gray matter of the cortex of the brain must be in a pure and plastic condition in order to receive and register the impressions and impulses coming through the sensory organs, the psychic intuition and the intellectual and emotional activities of the mind. Anything in the way of physical impurity or foreign matter that tends to clog the brain, or to feed it with waste and morbid materials, or with corroding poisons, will lessen the atomic and molecular motility of brain and nerve matter, and will interfere with, or impede, the groupings and subtle transformations involved in the fashioning of brain centers through mental and emotional influences.

If the nutrient blood which feeds the brain substance of the fetus be saturated with CO$_2$, the benumbing, paralyzing carbon-dioxide, with clogging uric acid or the destructive acids of phosphorus and sulfur, the gray matter cannot respond to the subtle and complex impressions and impulses from without and within.

The purity or impurity of the plastic matrix of the cortex depends upon the materials absorbed from food and drink. If these are so constituted as to create in the system excessive amounts of clogging and corroding substances, then these food and drink poisons will have a benumbing and deteriorating effect upon the sensitive gray matter of the brain, as well as upon the coarser tissues in the joints, muscles and vital organs. There is a rheumatism of the mind as well as of the joints.

A brain asphyxiated and clogged with pathogenic materials cannot be alert and active; it is too dull and lazy to think; it would much rather sleep than work; it is incapable of doing its best when its tiny blood and lymph vessels are obstructed with waste and morbid deposits which prevent the oxygenation and drainage of its delicately organized cellular tissues.
This, of course, is true postnatally as well as prenatally. A brain originally capable of the highest and finest achievements of the human mind may become utterly worthless, and may degenerate into idiocy through food, drink and drug poisoning.

Medical men tell mothers they need not worry over prenatal feeding, because the placenta, the vascular bag which forms the nest of the new life, acts as a filter which purifies the blood before it reaches the fetus. Common sense and every day experience tell another story. Even the best in the blood of many mothers is bad enough to serve as food for the new life.

The placenta does not filter out of the blood of the mother all food, disease and drug poisons. This is proved by the wretched condition of many infants, suffering from malnutrition, anemia and rachitis, after delivery. If the vital fluids of the mother are deficient in the mineral elements, or in other important nutritive substances, how can they deliver them to the fetus?

Occurrences like the following, quite common in our institutional practice, prove positively that the placenta is not a perfect filter for systemic poisons and for disease taints circulating in the blood of the mother.

One of the most pitiable cases of eczema in a little child less than one year old we traced to the fact that the mother, during her first year of marriage, had traveled with her husband through Eastern European and Asiatic countries, and during her pregnancy had been vaccinated five times while passing through localities where smallpox was prevalent. Both she and her husband had always enjoyed perfect health. The family record was excellent as far as traceable; still the body of the infant soon after birth, was covered with open bleeding sores, presenting a revolting sight. We could find no explanation for this strange phenomenon other than the many vaccinations during pregnancy. These had contaminated the blood of the mother, and through her the body of the fetus, with a filthy scrofulous taint.

The baby suffered terribly. For many months it slept but little, because of the excruciating pains. The eczematous eruptions were of a very stubborn nature; they broke forth again and again. Finally, however, after eighteen months of natural treatment, we succeeded in purifying the little body of the horrible infection. The child is now a little over three years old, in perfect health, and during the last twelve months has shown no signs of the morbid taint.

Under another section I shall describe the influence of food upon character and sex life.

To recapitulate: Purity, plasticity and motility of the highly refined and sensitive materials which make up the gray matter of the brain depend upon pure food, plenty of fresh air and exercise, and upon all other natural methods of living.
SECTION XXXV

Conception and Pregnancy

1. Conception takes place whenever the male spermatozoon joins the female ovum (egg) within the woman's womb. Normally the female organism liberates from its ovaries but one ovum each month, usually during menstruation, while the male discharges millions of spermatozoa at each orgasm.

Conception does not always follow copulation. The ovum remains in the womb and is capable of impregnation for about five days after menstruation. The spermatozoon on entering the womb may meet an ovum which has been discharged at a previous menstruation, or it may remain alive in the womb for a number of days and finally come in contact with a newly discharged ovum at the following menstruation.

The spermatozoon retains its ability to impregnate the ovum for from ten to fifteen days after its discharge into the womb. When the male and female germs merge into one another, conception or impregnation takes place. As soon as this has happened, the impregnated ovum becomes attached to the inner lining or mucous membrane of the womb and begins its new life as an embryo. The period comprising the time from the impregnation of the ovum until the beginning of labor or childbirth is called pregnancy.

The table of pregnancy on page 377 indicates the probable date of normal termination of a pregnancy, calculated from the last menstruation.

2. Exercise During Pregnancy. Unfortunately a great many expectant mothers labor under the idea that they must rest and be relieved from work and exercise. This of course is a great mistake. Light housework is good exercise. There is nothing more harmful during pregnancy than nursing "that tired feeling" by lounging idly about the house and coddling one's real or imaginary aches and troubles.

Of great benefit to the pregnant woman are all outdoor sports such as tennis, golf and other games which require vigorous exercise without straining or overworking the body. The great benefit of walking and other outdoor exercises, aside from their general invigorating effects, lies in the strengthening of the abdominal muscles and ligaments, which at delivery will greatly facilitate expulsion of the fetus.

The walk should be brisk and rhythmical, body erect, head thrown back, chest forward; the breathing at the same time should be deep and regular. These walks should be continued as long as time and endurance permit. Nothing, of course,
must be pushed to the point of exhaustion. One good long walk every day is necessary; two are better.

We all understand the necessity for a plentiful supply of oxygen under ordinary conditions, and especially in time of illness. During pregnancy the demand for oxygen, as well as for mineral salts, is doubled or trebled on account of the needs of the rapidly developing organism in the womb of the mother.

These extra demands for oxygen and ozone must be supplied by systematic deep breathing, cold bathing, outdoor walks, etc. If circumstances do not permit the taking of outdoor exercise, deep breathing should be practiced as often as feasible, at the open window.

Next in importance among gymnastic exercises is the internal massage described under section XXI, No.16.

Those exercises are especially valuable which bring into play the abdominal muscles and the muscles and ligaments of the genital organs.

3. Clothing. Clothing and the manner of wearing it profoundly influences the normal or abnormal development of the fetus, the health of the mother, labor and delivery.

At no time should the waistline be constricted by a corset or even by the ordinary skirt band. All clothing should be as loose and light as possible—one-piece under and outer garments, with the weight suspended from the shoulders, are best. If skirts are worn they should be fastened to skeleton waists of some thin cotton material. The close, heavy texture of the material from which the corset or so called "reform waist" is made is injurious because it interferes with skin elimination.

Even the slightest constriction of the waist line interferes with the free circulation and the normal blood supply to the abdominal organs, which is of especial importance in pregnancy; it also hinders the free expansion and movement of the uterus during the various stages of pregnancy.

Within the waistline are located a dozen or more important vital organs of the body. Any sort of constriction compresses these organs and pushes them out of their normal position. While this is extremely injurious to the body of a woman under ordinary conditions, it is doubly so to the pregnant mother and to the rapidly growing fetus. Undoubtedly many deformities and monstrosities are produced by unnatural constriction of the blood vessels and vital organs in the abdomen and pelvis of the pregnant woman.

If due attention is paid to the foregoing influences, labor and delivery will be brief and easy. This we have proved in hundreds of cases which have come under our management. The reason why women of civilized countries spend many
hours and sometimes days in dreadful agony of childbirth while those of primitive or savage races, as we call them, produce their young easily and painlessly as the animals do, is that primitive women live more simple and natural lives, while "civilized" mothers violate practically every law of Nature in their daily habits of living.

Civilization unfortunately stands in many respects for that which is artificial, unnatural and therefore productive of disease and suffering in all domains of life, not only as regards physical health, but social and political health as well.

SECTION XXXVI

Danger Signs During Pregnancy

1. Dropsical Swelling. Swelling of the limbs and distention of the veins of the legs during pregnancy may be caused by a tendency towards varicosity, intensified by obstruction of the circulation due to the enlarged uterus. Such a condition requires, aside from the natural regimen, careful and competent treatment.

Swelling of the limbs or other parts of the body may also be caused by incipient or advanced Bright's disease. The urine should be examined from time to time, especially if there is a swelling of the feet and ankles, or if there are dropsical symptoms in other parts of the body.

Such dangerous conditions are usually brought about through the excessive intake of starchy and protein foods which overwork the liver and kidneys and cause pathogenic dogging of the capillary circulation. This may result in uremia attended by violent and sometimes fatal Convulsions.

2. Uremia is the result of retention in the system of waste materials and poisons that should be eliminated through the kidneys and skin. Medical treatment for such conditions, aside from the administration of stimulating drags, consists in hot bathing with the idea of opening the pores of the skin.

We understand that all hot water treatment gives only temporary relief and is followed by greater enervation and inactivity of the skin. The best water treatment for systemic poisoning of any kind consists in the application of wet packs followed by cold ablutions as described in section XV.

The addition to the packs, dry friction rubs, air bath, good massage and neurotherapy treatment will aid in restoring the normal activity of skin, bowels and kidneys.

Whenever the urine contains sugar or albumen, fasting, alternating with raw food diet, is indicated. Suitable regimens are outlined in sections X, XI.
The giving of heavy food to the mother with the idea of increasing the flow of milk is all-wrong. We have found in all cases that the diet outlined in section X will produce a more copious flow of rich milk than lie "nourishing" meat diet. The best remedy for a scanty flow of milk is slow and thorough mastication of a few spoonfuls of raw crushed wheat every day.

3. Morning Sickness. One of the common disorders experienced during pregnancy is that known as Morning Sickness. One suffering from this ailment, though following a natural diet, should sip a cup of hot postum while remaining in bed. If this does not have the desired effect and if the patient has not been accustomed to drinking coffee, half a cup of black coffee with a few drops of lemon juice will quiet the irritated nerves. It is necessary after taking the hot drink to remain in bed for at least thirty minutes. It is understood that this is only an emergency measure. If continued, it will lose its good effect and work injury.

SECTION XXXVII

Labor and Delivery

At about forty weeks, exactly nine solar months, from the period of conception the fetus reaches full maturity, and labor begins. Labor is divided into three stages. During the first stage the neck of the womb becomes slowly and gradually distended and the orifice of the womb opens widely. When this has taken place, the fetal membranes burst and the amniotic liquid surrounding the fetus escapes.

During the second stage the fetus emerges from the womb.

After expulsion of the fetus, the placenta is expelled from the uterine cavity. This constitutes the third stage of labor.

The first stage usually begins with more or less radiating pains in the abdomen, accompanied by dull pain in the small of the back and a drawing pain in the limbs. Sometimes women with the first baby feel these pains weeks in advance of the actual commencement of labor. At first they occur at long intervals and are of short duration, but gradually become more prolonged and more frequent. The pains are due to a cramp-like contraction of the muscular apparatus of the uterus forcing its contents downward.

Under this pressure from above, the neck and mouth of the uterus distend to their limits, and the walls become thinner and thinner. First the inner, then the outer orifice of the neck of the womb opens and the fetal membranes protrude and finally rupture, allowing the amniotic fluid to escape. Shortly after this the part of the fetus nearest the orifice, normally the
head, makes its appearance. At the present time the average duration of the first stage of labor is six hours, but it may last twenty-four hours or longer, depending upon the plasticity and elasticity of the bony structures of mother and infant, the rigidity of the cervix, and the vigor or lack of vigor of the muscular apparatus of the uterus.

While the foregoing is true of the average delivery under ordinary ways of living, we find that after the enforcement of a natural regimen of living during and, better still, before pregnancy, the entire period of labor and delivery does not cover more than half an hour, or at the utmost from one to two hours. Even the disadvantages of slight build and smallness of pelvis can be overcome by the natural regimen outlined in section X. When our youngest child was born, the mother gave the first sign of pain at about midnight. I rose from bed instantly, but had not time to finish clothing when the membranes broke. Within twenty minutes after the commencement of labor the infant was resting in my hands.

The wife of a prominent lawyer in a western city had experienced three difficult deliveries. Each time surgical instruments had to be used and she had suffered untold agonies lasting from 24 to 36 hours. When she became pregnant the fourth time the most prominent physicians in her home city assured husband and wife that it was not safe for her to go through another delivery, that the womb was in worse condition than ever before therefore they recommended surgical removal. For conscientious reasons, however, the husband and wife did not follow the advice of the doctors, but decided to try natural methods of treatment.

The lady placed herself under our care during the fifth month of pregnancy. From that time on she followed strictly the natural regimen of living and received daily the usual hydropathic and manipulative treatments. This was continued until a few weeks before delivery. In this case the baby was born within an hour from the first contraction, and the mother of the patient, who was in an adjoining room, had not heard a sound. Many similar experiences refute the idea that it is unsafe and injurious for pregnant women to undergo the ordinary methods of natural treatment, such as hydropathic sprays, sitz baths, massage, Swedish movement and other forms of manipulation.

1. Preparation for Delivery. The diet during the last week before the beginning of labor should be very light, consisting mostly of fruits and vegetables. From the commencement of labor no food at all should be given, until at least twenty-four hours after delivery; a three-day fast is better.

In addition to a competent physician, a nurse or midwife should be engaged. If a good neurotherapist, who has had sufficient experience in obstetrical work, can be procured, he should be preferred, because he can assist delivery and make it much easier by manipulative treatment.
The nurse will make the necessary preparations and provide the various supplies needed in labor. With the first sign of approaching labor, the physician in charge should be summoned. A rectal enema of one pint or more of warm salt water (See. XVIII, No.4) should be administered. The woman should be given a vigorous cold rub and her genitals thoroughly cleansed. She may then remain on her feet and walk about, comfortably dressed, until actual labor commences.

2. No Anesthetics. The attending physician should not be impatient to hasten delivery with drugs or instruments. The use of anesthetics should be avoided insofar as this is possible. They should be employed only when absolutely necessary—that is, when excessive pain must be allayed or when surgical delivery is unavoidable.

3. Breaking of Water Bag. When the bag of water is about ready to break, the patient is placed in bed. Premature discharge of the amniotic fluid must be guarded against. An escape of the liquid at an early stage means difficult and prolonged labor, commonly known as "dry labor". Usually the membranes burst when the orifice is fully dilated. A large sponge is held in readiness to catch the out-flowing liquid.

3 a. Umbilical Cord. When the infant has been delivered, the umbilical cord should not be severed at once. Plenty of time should be allowed for the blood to transfuse itself from the body of the mother to that of the child. This is important. If the connection is severed too soon, the child begins life in an anemic condition.

The newborn baby usually greets the world with a lusty cry. It should be placed on its right side with its face turned away from the mother, care being taken that the cord is not stretched tight. As soon as the cord stops pulsating, plenty of time being allowed for blood transfusion, it is tied about two inches away from the baby's abdomen and cut a little above the ligature. The baby is now wrapped in a warm blanket and put in its crib.

4. After Delivery. Immediately after the baby is born, the nurse or attending physician gently compresses the abdomen and womb of the mother, kneading and rubbing it occasionally in order to secure complete contraction and thus prevent hemorrhage. After delivery the mother enjoys a period of rest and recuperation which usually lasts for about half an hour.

5. Afterbirth. Meanwhile the placenta becomes detached, and when the pains set in again a few contractions usually suffice to expel it with all the membranes.

The attending physician must make sure that none of it is left in the body, since this might result in putrefaction of the remains and blood poisoning. The woman's genitals should be washed with clean sterilized water.
The exhausted woman should now enjoy a deep, wholesome sleep and awaken from it in a few hours refreshed and strengthened.

In the foregoing I have not gone into the details of obstetrics and of technical management because this must be left to a competent obstetrician. I have called attention only to those points which are of special importance from the viewpoint of Natural Therapeutics and to the differences in treatment between the conventional and natural methods.

6. The Lying-In Period. The lying-in period varies from five to twelve days, according to the constitution of the mother and the care that she has taken during pregnancy. The greatest danger of the lying-in period is puerperal sepsis or blood poisoning. This condition is the result of infection occurring during labor, or it may result from the retention of parts of the placenta.

The only way to prevent this is by observing the most scrupulous cleanliness during the entire process of childbirth and during the lying-in period. When blood poisoning has developed it must be treated the same as all other acute inflammatory diseases (see section IX).

7. Care of the Newborn. The child should begin to breathe immediately after the cord is cut. If it fails to do this, the physician should lift the baby by its feet to facilitate the escape of mucus from the trachea and throat. If necessary the mucus must be removed from the throat by the insertion of the little finger, or by means of a tiny stick covered with gauze.

Breathing may be accelerated effectively by a few sharp taps on shoulders and buttocks. If this fails to bring the desired result, artificial respiration must be resorted to at once. The attendant grasps the child by its shoulders, its head resting between his palms and the two index fingers being hooked under the child's armpits. It is now swung between the physician's legs and lifted high above his head so as to be turned upside down. This is repeated from fifteen to twenty times, after which it is placed in a basin containing a few inches of warm water. Its body should then be rubbed briskly with cold water.

Father Kneipp used to take the newborn babe by the nape of the neck and the feet and submerge it quickly in cold water. This, a few times repeated, is probably the quickest way of resuscitating an asphyxiated baby.

In order to soften the cheesy deposit which frequently covers the body of the newborn, it is well to rub the skin with warm olive oil. After the greasy covering has sufficiently softened it may be removed with bits of gauze. This is followed by a cleansing bath with warm water and castile soap.
After the warm cleansing bath, the little body should be quickly rubbed down with cold water, wrapped in a soft, warm blanket and laid away to sleep until it wakens of its own accord. A normal baby should sleep for about twelve hours, and must not be disturbed to force food on it before it is ready to take it.

8. Bathing. From the first day, the baby must have a morning and evening bath. This consists, as before described, in a quick, cleansing bath of warm water and castile soap, followed immediately by a brisk cold rub. In the course of a few weeks the baby can be placed, for the cleansing bath, in a small bathtub containing a few inches of warm water. Immediately after the cleansing bath the warm water is replaced by cold water. This is taken up in the hollow of the hand and briskly applied to the little body. In this fashion the child, within a few months time, will enjoy its cold rub just as much as an adult. I have seen several such nature cure babies, but a few months old, object most vigorously to a warm bath. The cold rub is the best preventive of chilling; but care must be taken that the temperature of the room where the bath is given is not below 70 deg.

The olive oil bath or rub, often recommended for premature babies or infants suffering from malnutrition, is very injurious, because it occludes the pores of the skin and prevents the elimination of poisonous gases and other morbid materials from the body. The skin is not an organ of digestion. Olive oil, like all other foods, must enter the body through the alimentary canal where, under the action of digestive ferments, it is broken down into its component elements which are then assimilated through the intestinal membranes. Oil absorbed through the skin is not digested, and it circulates in the body as foreign matter which in this state cannot be assimilated and utilized in the system.

9. Powdering after the bath is fully as injurious as the rubbing with oils or massage creams. Powders and creams tend to clog the pores, and most of them contain poisonous antiseptics which lower the vitality of the skin and prevent or suppress elimination in the form of skin eruptions, eczemas, etc. For chafing use nothing but cold water. In case the chafing should become unusually severe and painful, through neglect by the caretaker, a soothing and healing lotion composed of one part lemon juice to two parts olive oil, may be applied a few times, until the irritation is under control.

10. Air Baths. Next to cold water, there is nothing that will invigorate baby's skin and nervous system as will the air and sun bath. If the season will not allow the outdoor air bath, the baby should be allowed to lie nude several times a day, for thirty minutes or more, in a warm, well ventilated and sunny room.

11. Constipation. Glycerin and suppositories should never be used; neither laxatives nor cathartics. Oat extract and cooling sitz baths will produce natural movements.
12. **Diarrhea** is a form of morbid elimination, and must never be suppressed by drugs. If it is habitual, bailey or wheat extract prepared in the same manner as oat extract, is a good remedy. If the diarrhea is persistent and of a violent nature, no food at all must be given, except water with dilute acid fruit juices, until the purging ceases. Even then plenty of time must be allowed for the rebuilding of the sloughed intestinal membranes.

13. **Bandages.** Until the umbilical cord dries up and falls off, it is necessary to cover the navel with a gauze compress dipped in olive oil. This is held in place by an abdominal bandage made of soft cotton material. These strips should not be hemmed, merely torn or cut. They should be drawn just snugly enough to hold the compress in place, but not tightly enough to interfere with circulation. The, navel must be cleansed and the compress renewed twice each day. After the umbilical cord has dropped off we no longer apply the abdominal bandage. This is contrary to common usage, but is the best practice. The abdominal bandage overheats the body and interferes with the free movement of the diaphragm and the circulation of the blood.

14. **Clothing.** The clothing of the infant should be loose and light and as simple as possible. Freedom of movement is very important; binding or pressure upon any part cannot help but interfere with the circulation, and otherwise produce injurious results. The clothes should be short, in order to allow the feet and legs free play. Light weight, porous cotton materials are best for both under and outer garments. A lightweight wool petticoat may be worn when absolutely necessary to provide sufficient protection for the baby. Cotton hose and bootees may be used, but under no circumstances should such articles be of wool, because it prevents free elimination from the skin. The baby's head should not be covered out of doors, except in severe weather. At no time should a veil be placed over the face, as it will cause the infant to reabsorb the poisonous exhalations from its own lungs. All clothing should be changed each day. No garment should be starched—such a practice is not only useless but harmful.

15. **Diapers** must be provided in sufficient number to allow thorough cleansing and drying. The wet diapers should be scalded in hot water and very thoroughly rinsed in several waters afterwards. They should then be dried in the open air and sunshine. Soiled diapers must be well washed and boiled. Washing powders, soda, ammonia and other chemicals should never be used. They have an extremely irritating effect upon the delicate skin of a baby. In order to save labor and to facilitate the cleansing of the diapers, small squares of clean old linen or muslin rags, or pieces of absorbent gauze, may be placed inside. These inserts will absorb all or most of the bowel movement and may then be burned. If the skin is irritated or chafed, the parts should be sponged off with clean cold water at each change, paying special attention to cleansing of the genitals. Oils or powders must not be used to soothe the sore places, because they clog the pores and
16. A wet nurse is to be preferred to artificial feeding. She should be thoroughly healthy, not over thirty years of age, of equitable temper, not excitable or nervous and her diet should be that prescribed for the mother.

17. Care of the Nipples. They should be thoroughly cleansed before and after nursing; not with carbolic acid, but with water and dilute lemon juice. The lemon juice tends also to harden the nipples. Treatment of the nipples may begin before the birth of the child.

18. Care of the Eyes. The baby's eyes, whether awake or asleep, should always be shielded from strong light, either sun or artificial, and from dust and wind. The eyes should be washed with cold water after every cleansing bath. If they show any tendency to weakness or disease, slight vibratory massage over the closed eyelids should be given after the cold eye bath.

19. Care of the Mouth. A healthy baby's mouth needs no cleaning before the arrival of teeth. As a matter of fact, the teeth of a perfectly healthy adult would not need cleaning any more than do those of an animal living in the freedom of nature. The saliva is a sterilizing fluid, under normal living, intended by Nature to keep the mouth clean and healthy. Cleansing of the mouth of an infant with the finger or with a cloth may injure its delicate membranes. If the mouth must be washed, in case of disease, a swab made by twisting a piece of sterilized absorbent cotton on the end of a smooth stick should be used. The swab should be dipped in warm boiled water, and the interior of the mouth washed thoroughly, the cotton then being burned.

20. Care of the Ears. The external ear should be cleansed with a soft rag or swab as before described. Never use a hard instrument inside the ear.

21. Care of the Nose. A baby's nose should be cleansed as a part of the daily toilet, in the same way as the ears. A swab may be made by twisting a, piece of gauze to a cone. As soon as the child becomes old enough, it should be taught to sniff up cold water through the nostrils and the nasal passages. This is the best way to keep the nasal membranes in a clean, healthy condition.

22. Care of the Genital Organs. The genital organs of both sexes must be kept scrupulously clean with as little handling as possible. The foreskin of the penis of the male baby should be drawn back at bathing time and the organ thoroughly cleansed, always finishing with cold water.

23. Phimosis. The treatment of phimosis is fully described under Sec. XXVIII, No.1.

24. How to Lift the Baby. The best way to lift a young
baby is to slip the left hand under the back beneath the shoulder, spreading out the fingers in such a way as to support the neck and head. Then lift the feet and legs with the right hand. **Never lift an infant without first supporting the spine.**

When a baby has grown strong enough to hold up its head and has gained considerable strength in the muscles of the back and neck, he may be lifted by grasping him with outspread fingers under the armpits; the body must be held firmly so that the entire strain does not come on the shoulders. A baby should never be lifted by the arms. This may dislocate the shoulder joints.

---

**SECTION XXXVIII**

**Prenatal Feeding**

1. **Effects of Diet During Pregnancy.** The problem of infant nutrition begins before birth. Prenatal feeding determines the physical start in life. On it depends not only the condition of the mother's health during pregnancy, but also the size and weight of the fetus, pliability of the bony structures, ease or difficulty of delivery, and the quality of the mother's milk.

The fleshier and heavier the newborn infant, the prouder and happier are the parents and the doctor. Yet, excessive size and weight of the child constitute the most prominent cause of difficult and painful childbirth and frequent necessity for instrumental delivery.

The biblical saying, "In sorrow thou shalt bring forth children"; has led many to believe that woman's dreadful suffering is a necessity, God ordained; but is not man's ignorance, rather than the cruelty of an avenging God, to blame?

This latter view is confirmed by the fact that other mammalia literally cast their young, without pain or difficulty; and the labor pains of primitive mothers are insignificant, their delivery presenting little more difficulty than that of the lower animals. A squaw on the Western Plains stops a few hours by the wayside to deliver her papoose and then resumes her journey as though nothing had happened.

Women among the European peasantry, who wear no corsets, live on black bread and vegetables, and have plenty of exercise in the fields and in the home to the last day of pregnancy, have their babies without help of midwife or physician and resume their usual routine of work within a few days after delivery.

Thousands of mothers who have adopted natural ways of
living have learned to dispense with anesthetics and the surgeon's instruments; they now bring forth their offspring without excessive pain.

2. Results of Faulty Diet. It is significant that the offspring of the lower animals, at birth, consist of little more than skin and bones, while the newborn human is often abnormally large and fat. This is especially true of babies born of weak and anemic mothers. As before stated, excessive size and weight of the infant is not a matter for congratulation, but is a pathological condition. It indicates fatty degeneration of the fetus, due to the anemic watery condition of the blood of the mother, and the cause of this hydremia of mother and child lies in the faulty dietetic habits of the former.

The ordinary diet of American women consists almost entirely of meat, fish, fowl, potatoes, white bread, pastry, coffee, tea and refined white sugar. The few vegetable, which enter into the daily dietary are first deprived of their all important organic salts by faulty cooking; fruits are looked upon as luxuries and frequently are regarded as harmful.

The anemic, watery condition of the blood of mother and child is not due to a lack of starchy, protein and fatty materials in food and blood, but to a deficiency of organic mineral elements. Neither is the anemic condition, as the regular school of medicine assumes, caused by lack of iron. Any ordinary food mixture, as well as the blood and milk of anemic mothers, usually contains a sufficient amount of iron. The actual cause of the anemia is a deficiency of other mineral elements.

As I have explained in Volume III of this Series, carbonic acid poisoning and the resulting sluggishness of the surface circulation, coldness of the extremities and congestion of the inner organs is not caused so much by a lack of the oxygen-carrying iron as by a deficiency of the carbonic acid neutralizing and eliminating sodium and magnesium.

If the blood is deficient in lime, phosphates, silicon and fluorine, rachitic conditions, softening of the bones, deformed spines and legs, and decay of the teeth, are inevitable results.

It is an easy matter to supply the daily needs of the organism for proteids, starches, fats and sugars; the difficulty lies in supplying a sufficient amount of the organic mineral elements.

The deficiency of sodium in human blood, Dr. Lahmann proved in the following table of comparative blood analyses. In a hundred parts of ash he found in the

</tbody>
</table>
The percentages of lime and of other positive mineral elements in the human blood are also much lower than in the blood of cows, oxen and sheep.

While the blood of cattle and sheep raised on pasture is very uniform in composition, hardly any two samples of human blood are alike. It is for this reason that Dr. Lahmann adopted cow's milk instead of human milk as the standard elementary food combination.

In the following table, he compares the percentages of minerals in the ash of cow's milk with the percentages of mineral elements in the ash of various other food materials.

A daily dietary consisting largely of meats, eggs, white bread, potatoes, peas and beans, though excessively rich in proteids, fats and starches, will, on account of its deficiency in sodium, lime and magnesium, inevitably result in carbonic acid poisoning, anemia, rachitis, premature decay of the teeth and a multitude of other acute and chronic ailments.

If, however, the daily dietary contains a liberal amount of green vegetables and fruits, a normal food mixture resembling that of cow's milk can easily be obtained. It must be remembered that fruits and vegetables are not only rich in the most important mineral salts, but that they are relatively poor in proteids and carbohydrates.

For this reason fruits and vegetables facilitate the establishment of an equilibrium between proteids and carbohydrates on the one hand and organic mineral salts on the other.

**3. Excessive Fat Formation.** We can now understand why the ordinary faulty diet of pregnant mothers causes anemia, softening of the bones, sluggish circulation, carbonic acid poisoning and fatty degeneration in mother and offspring.

Lack of sodium causes excessive accumulation of carbonic acid, and oxygen starvation. This results in defective
oxidation of food and waste materials; in other words, in fat formation.

Defective draft prevents the complete consumption of coal, and chokes the furnace with the products of imperfect combustion. Similarly, lack of oxygen in the tissues (due to carbonic acid poisoning) causes an incomplete combustion of food materials and waste products, resulting in fat formation and in the generation of poisonous byproducts.

Lack of sodium also prevents the neutralization and elimination of uric and other acids and ptomaines (pathogenic matter) which accumulate in the tissues, block the circulation and assist in the smothering of the vital processes.

In order to eliminate these pathogenic materials, there arises an abnormal craving for water—"the anemic thirst"—which is closely related to the thirst of fever patients and of diabetics. Excessive water drinking is encouraged by the popular "flushing" fad.

To make things worse, the anemic, for reasons before stated, usually suffers from weak heart action and sluggish circulation. This means defective elimination of water through the skin and kidneys, resulting in a watery (dropsical) condition of the tissues and fatty degeneration.

Not all anemic, carbonic-acid-poisoned mothers, however, develop a tendency to obesity. On the contrary, under certain constitutional conditions, they may become exceedingly lean, like the anemic, carbonic-acid-poisoned consumptive. Briefly stated, sluggish heart action and weak kidneys favor retention of carbonic acid and water in the tissues and thus make for fatty degeneration. Good circulation and normal activity of the kidneys may keep the system free from excess of water and carbonic acid, but excessive proteids in the diet may result in sulfuric and phosphoric acid poisoning. These destructive acids break down the tissues, rob them of their mineral constituents, and thus cause excessive loss of flesh and fat.

In both types of dysemia the blood of the pregnant mother is overloaded with poisonous gases, waste matter and the debris of broken-down tissues. The oxygen supply to the fetus is therefore very much impeded and we find that both fleshy and lean mothers produce babies of abnormal size and weight, ranging from eight to twelve pounds, while the normal weight of the newborn should not be more than six pounds.

4. Advantages of Natural Regimen. We know of many instances where mothers, after having given birth to heavy, fleshy babies, in subsequent births have reduced the weight of the new born to normal, and the pain of delivery to a minimum, by the adoption of a natural diet, plenty of exercise in the fresh air and systematic deep breathing.
The effects of a natural regimen are manifested in various other ways. The bony and muscular structures of mother and child are much more pliable and elastic, making parturition and delivery much easier. Pure blood, normal nutrition and abdominal exercises, walking and special gymnastics, greatly strengthen the abdominal and uterine muscles, thus facilitating expulsion of the fetus.

The morning cold rub, systematic deep breathing and general exercises, every day outdoor walks and right mental and emotional attitude are all of paramount importance in the regimen of pregnancy.

The Regimen for Wholesome Living, section I, is admirably adapted for all the needs of the pregnant mother.

SECTION XXXIX

Postnatal Feeding

Thanks to the educational influence of nature cure propaganda, a decided change for the better in baby feeding has taken place during the past ten years. Up to that time the "top cream mixture" was universally recommended by allopathic physicians and given to babies by trained nurses.

While in the meantime many physicians and nurses have adopted more natural methods, the "top cream mixture" is still too common and must be entirely abolished in order to safeguard the health of our little ones.

In the February, 1909, issue of the Nature Cure Magazine, I commented upon this subject as follows:

1. Bottle-fed Babies. Our food analyses disclose the interesting fact that the elementary composition of the ash of the milk of an animal is about the same as the composition of the ash of its body.

They also show that good cow's milk when normal comes closer to the requirements of the infant body than does inferior human milk.

Our tables of food analyses show that chemically the composition of cow's milk and of human milk is very much the same. Human milk contains a little less proteid and a little more sugar than cow's milk, and the latter is much richer in organic salts than the former. There is much more of the all-important sodium in cow's milk than in human milk and about twice as much calcium (lime) and iron (table p.100). This explains why rachitis is so common among babies, while never found among calves.

As we have learned, the elimination of poisonous acids
from the body depends on sodium. The building of the bony structures depends on lime; the oxygenation of the blood, on iron.

Many years of practical experience in the care of babies has convinced me that milk fresh from a healthy cow is greatly to be preferred, as nourishment for infants, to the impoverished milk of scrofulous mothers.* In this connection it is significant that one-half of all "civilized" mothers, thanks to unnatural food and drink, vaccination and poisonous drugs, are incapacitated for nursing their offspring.

* This may not be true in the future if our milk cows continue to be regularly subjected to tuberculin tests.

To one who has studied the comparative analyses of cow's milk and human milk, it is incomprehensible why the former, when given to infants, should be diluted and spoiled by large quantities of water, salt, soda and inorganic mineral lime (in the form of lime water).

This procedure, however, is still frequently recommended by physicians of the regular school. Undoubtedly, the great frequency of anemic and rachitic diseases, the darkening of the iris, appearance of scurf rim, and the signs of catarrhal conditions in stomach and bowels are caused by such unnatural feeding.

The following extracts are taken from an article entitled "Bottle-fed Babies", in the Ladies' Home Journal. It was written by Dr. Emelyn Lincoln Coolidge, of the Babies' hospital, New York. Thousands of mothers, on account of the high standing and excellent reputation of this family journal, undoubtedly have followed, without question or misgiving, the advice presented.

The formulas given below are for the average healthy baby, and are called "cream" or "top milk" mixtures.

"Food for the first month. With a spoon, or a tiny dipper which comes for this purpose, carefully skim off the top six ounces from a quart bottle of milk; to this add twenty-four ounces of water which has been boiled and cooled, and in which has been dissolved three teaspoonfuls of granulated or six of milk sugar; next add a pinch of bicarbonate of soda and a small pinch of salt; mix this all thoroughly, and pour enough for each feeding into ten separate bottles& Then cork the bottles family with cotton and either Pasteurize the milk or stand it on the ice.

"For the second month. Skim off six ounces of cream, then pour off three ounces of milk; add twenty-four ounces of water and the same amount of sugar, salt and soda as above; mix and bottle.

"For the third and fourth months. Cream, six ounces; milk, six Ounces; water, twelve ounces; barley or oatmeal gruel, twelve ounces; sugar, salt and soda as usual, etc.

Plain Milk Formulas

"Pour the entire quart of bottled milk out into a clean pitcher and then back into the bottle several times, thus thoroughly mixing the milk; then take:
"For the first month. Six ounces of milk, twenty-four ounces of barley-water, half a tablespoonful of granulated or one of milk sugar, a pinch of bicarbonate of soda; mix all well together and pour the proper number of ounces into separate bottles, and either Pasteurize or place on ice.

"For the second month. Nine ounces of milk, twenty-one ounces of barley-water, one tablespoonful of sugar, and a pinch of soda."

Physicians would never think of giving such advice as this, if they were acquainted with natural dietetics founded on exact and complete analyses made by food chemists of the nature cure school.

I have already called attention to the fact that food chemistry, whether practiced in allopathic colleges, in great sanitariums or by vegetarian food reformers, deals with proteids, starches, fats and sugars only, and leaves entirely out of consideration the all important mineral elements or organic salts of potassium, sodium, iron, lime and magnesium.*

*This was true at the time this article was published in the Nature Cure Magazine.

On these five positive mineral salts, as we have shown, depend all the important vital functions of the human organism, while proteids, starches, fats and sugars serve only as building and fuel material.

The digestion of the proteid and carbohydrate foods, as well as the elimination of the waste matter resulting there from, depends upon the positive organic mineral salts.

Study carefully these recipes for baby feeding, taken from the Ladies' Home Journal, and compare the mixtures with the analyses of cow's milk and human milk in the accompanying tables.

Let us consider the "top milk" mixture, prescribed for the first month. The cream rising to the top is almost pure fat. The all-important mineral elements plus the nourishing milk sugar and proteids remain in the skimmed milk, which is looked upon as worthless and fed to the pigs.

Our food analyses (see tables in Volume III, Cook Book) show that the ordinary brands of flour are almost devoid of mineral elements. Furthermore, one teaspoonful of barley to one pint of hot water does not mean much in food values. Where in these six ounces of cream (fat) and twenty-four ounces of barley water is baby to get the necessary amount of sugar for fuel material, of proteid for tissue-building, of lime for bone-building, of iron for oxygen-carrying, and of sodium, magnesium and potassium for the processes of elimination?

It seems that these deficiencies are intended to be overcome by baking soda, mineral table salt and the lime water, so generally prescribed by physicians. Many times I have demonstrated that inorganic mineral salts, with the possible exception of a little table salt, should not enter the animal or human organism, that these salts must first be organized,
made alive in the plant or animal cell, before they are wholesome food for animals or human beings. I have shown that, taken habitually in the mineral form, these salts accumulate in the human body, act as irritants and poisons and reveal their presence in the iris of the eye.

I fail to understand why the tender and sensitive organism of the newborn infant should be encumbered with inorganic minerals while cow's milk contains them in ideal form, made alive first in the grasses and grains, then still more highly organized and magnetized in the body of the animal.

It is bad enough to give mineral sodium, lime and table salt to an adult, but it is little short of criminal to give them to babies under the guise of foods and medicines.

The cream mixtures are readily digested, because there is not much to digest. The fact that infants thus fed cry for food continually is good evidence that their needs are not satisfied. Babies fed with this sort of slop grow fat for a while. The watery food inevitably produces fatty degeneration. This for a season swamps the little body with unhealthy fat. But the first crisis which happens along often takes away not only the unnatural fat, but the baby also.

The artificial mixtures contain entirely too much water in proportion to nourishing elements. The resulting malnutrition and the constant irritation caused by the inorganic minerals result in chronic diarrhea or constipation.

The Right Way

The best food for the newborn and growing infant is undoubtedly the mother's milk, provided that she is herself in fairly good health. Unfortunately, many mothers are unable to nurse their offspring, and if a healthy wet nurse cannot be secured, other food must be provided.

The best substitute for human milk, without question, is cow's milk, fresh, pure and undiluted, as it comes from the animal.

"Why", indignantly exclaims the trained nurse, when we give these instructions, "undiluted cow's milk is altogether too rich, it is indigestible for baby; if the milk is not boiled or pasteurized, germs and bacilli will surely create infectious diseases".

To this we answer: Our analyses show that the difference in composition between cow's milk and human milk is not enough to affect the infant. The danger lies not so much in overfeeding on "rich" cow's milk as in underfeeding on watery milk and cereal dilutions, and in poisoning the little body with inorganic minerals.

As regards germ infection and the necessity for pasteurizing the milk, the menace to health and life is greater through
malnutrition than through germs and bacteria. Germs we cannot escape, not even if we were surrounded on all sides by walls of air-purifying and antiseptic materials.*

*Since the foregoing was written we have learned that low vitality and morbid soil will develop perfectly normal microzyma into so-called disease germs.

One of the foremost French bacteriologists claims that in the mouths of infants shortly after birth he has found almost every disease bacillus known to medical science.

William Osler; M.D., to whom the English language is indebted for the verb "to oslerize," says in The Principals and Practice of Medicine on page 151, in the chapter on Diphtheria:

"The presence of the Klebs-Loeffler bacillus is regarded by bacteriologists as the sole criterion of true diphtheria, and as this organism may be associated with all grades of throat affections, from a simple catarrh to a sloughing, gangrenous process, it is evident that in many instances there will be a striking discrepancy between the clinical and the bacteriological diagnosis."

In the first part of this sentence he states that bacteriologists regard as the sole criterion for the diagnosis of diphtheria the Klebs-Loeffler, or diphtheria, bacillus; in the last part of the sentence he admits that this bacillus is found in even slight catarrhal conditions, and he might add that it is found just as frequently in the mouth and throat of healthy infants and adults. This is a good example of "orthodox" scientific reasoning.

If germs and bacilli of themselves could destroy health and life, the human race would in a short time become extinct. Disease germs are omnipresent. They permeate the tissues of our bodies and in the intestinal tract swarm by millions. Whether they prevail depends upon natural resistance, or reserve force, and upon the disease soils in the system. The air we breathe is saturated with all sorts of disease germs or their microzyma.

Since baby cannot escape germ invasion, the real problem is how to increase the resistance of the little organism and how to purify it of morbid matter so that disease germs will not find anything to feed on.

Resistance depends largely upon proper nutrition. Diluted, watery milk, contaminated by inorganic minerals, is not a good nutrient; its nutritive value is still more reduced by pasteurizing or boiling. Heating milk or any other proteid food above 1500 F. coagulates the albumen, disorganizes organic compounds, precipitates salts and dissipates the life elements. This reduces the nourishing value and digestibility of the milk.

Nature does not provide the young animal with boiled or
pasteurized milk, and we should not lower food values by such methods.*

* It is now admitted that pasteurization and boiling kills "newly discovered vitamins" which are the "life elements" constantly referred to in my earlier writings.

I do not wish to intimate, however, that scrupulous care and cleanliness should not be exercised in the selection and handling of the milk.

Wherever possible, secure the milk of a single healthy cow that grazes on green pastures or is fed on normal clean food mixtures. Milk from cows kept in stables and fed on brewery and distillery slops and other refuse should not be used.

Every vessel and utensil with which the milk comes in contact must be carefully scoured, submerged in boiling water, drained and kept in a light, airy place.

The nursing bottle, after each feeding, must be taken apart and carefully scrubbed, inside and out, in hot water with an addition of a little soda. It should then be left in pure, cold water, until the next feeding time.

2. When to Feed. Physicians quite generally recommend feedings at stated hours, in fixed quantities.

This is altogether wrong, it establishes at once the stuffing habit, does not permit the development of natural desire and its regulation. The infant very soon becomes accustomed to eating at certain times, whether it really needs the food or not.

Food should not be given until there is an actual demand for it, which will express itself in real hunger. By careful observation and experiment the mother will soon learn to distinguish the ordinary crying of the baby and the desire for food expressed by it. If this practice of feeding only when there is a natural desire for food is strictly followed, the infant will soon establish its own regular feeding times, usually at intervals of about three or four hours in the daytime. The stomach digestion of a feeding of milk will require about three hours, therefore a minimum of that much time should be allowed between feedings after the first few weeks.

If the mother can nurse her baby, it should be put to the breast upon awakening from its first sleep, either before or after bathing and dressing.

The first secretion of the breasts (colostrum) is not really a food, but performs an important function in cleansing the intestinal tract and preparing the digestive system to properly digest and assimilate the milk when it comes, usually about the third day.

3. How to Feed. If artificial feeding must be resorted to, no food at all should be given, except a few teaspoonfuls of water, during the first twenty-four hours after birth. During
the next few days, cow's milk should be given, well diluted—about one-half milk and one-half filtered or boiled water. From week to week the amount of water should be reduced until at the end of the second month the baby takes cow's milk undiluted.

4. Night Feeding. In the nighttime feeding should not be encouraged. During the first four months it is advisable to feed not more than once during the night. After that the child should be weaned from the habit entirely. This will be facilitated by giving a drink of water instead of milk.

5. Amount of Food. Discretion should be observed in determining the amount of food. Do not induce the baby to take as much as possible, rather as little as possible. Its welfare does not depend upon the amount of food consumed, but upon the amount which it can easily digest and assimilate.

When more food is given than the digestive organs can take care of, the entire mass may ferment and sour.

6. Grain Extracts. If undiluted milk proves too rich, grain water may be added. In order to prepare this, take clean grain as it comes from the field, crush it in a hand grain mill or a new coffee mill, take three tablespoonfuls of the crushed grain to one pint of cold water, and boil on the stove for one hour; or in the fireless cooker for two or three hours, in which ease use a little more water at the start. While the gruel is boiling over the fire, add enough water to allow for evaporation and absorption. When thoroughly cooked, strain the gruel through a fine cloth or sieve. Add one tablespoonful, or more if necessary, to each milk feeding.

When baby is constipated, add to the milk, grain extract made from oats, and frequently cool the bowels with cold water. This will cure the most stubborn constipation. If the bowels are too loose, add to the milk, extract made from barley or wheat.

The small particles of hulls in the grain extracts improve digestion and evacuation, in a mechanical manner. They permeate the curds and keep them from coagulating too solidly, thereby facilitating the penetration of digestive juices; they also exert a mild stimulation on the walls of the intestines, thereby increasing the peristalsis of the bowels and evacuation of feces.

7. Baby's Natural Medicines. Fruit juices and scraped raw ripe pear or apple and the pulp of cooked fruits such as prunes or figs without addition of sugar or sweetening of any kind, are baby's finest medicines. They increase the supply of organic salts for blood, nerve and bone building and for purposes of elimination. They are nature's own chologogues, laxatives, tonics and antiseptics. They keep the little body sweet and wholesome. All babies under our care receive fruit juices beginning with the second week.
During the first two months, give one teaspoonful of orange juice, grape fruit juice or prune juice, one hour before or after each nursing. After the second month, gradually increase the amounts of fruit juices and begin to add raw pear or apple scraped with a spoon or dull knife, or the mashed pulp of fully ripened peach or grapes.

8. Weaning the Baby. Nursing infants should be weaned from the breast after the eighth or ninth month. From the sixth or seventh month, both nursing and bottle-fed babies should begin to take some solid food. The best of these to begin with are whole-grain cereals, gruels, raw and cooked fruits and tender vegetables in small amounts. Mealy baked potato is one of the best foods, better than the cereals.

9. Feeding After First Year. After the lapse of the first year, the solid foods are gradually increased and the milk reduced in quantity. Eggs should not be given before the eighteenth month, then soft-boiled or poached. During the second and third year half an egg twice or three times a week is sufficient; after that an egg at a time may be given once or twice a week.

Meat and all other foods prepared from the dead animal carcass are bad enough for adults, but it is inexcusable to give them to tender infants and children.

Dog fanciers, when they sell a valuable canine, usually advise the buyer not to give the animal any meat before the second year, lest it become a victim of distemper; and dogs are naturally meat eaters.

Well informed physicians now generally advise not to give meat to children before the fifth or sixth year. They have learned this much from the nature cure people.

Foods undoubtedly have a powerful influence, not only on the physical body, but also on the mentality and the emotions. These problems will be interesting subjects of investigation for the food chemist and psychologist of the future. In general, we may say that flesh foods are stimulating and feed the passional nature, while fruits and tender vegetables refine and stimulate brain and nerve matter as well as the intellectual, emotional and spiritual activities. Cereals, nuts and pulses build and repair the physical body and supply the body with heat and muscular energy.

The majority of animals adhere strictly to one kind of food, and therefore faithfully exhibit in their mental and emotional characteristics the effects of different food materials. Ferociousness we find personified in the carnivorous bulldog, lion, tiger and panther (that is why soldiers are fed on meat three times a day); gluttony and omnivorous voraciousness in the hog, chicken and hyena; cold-blooded cunning in the fox, and cruelty in the cat. The intelligence of the carnivorous animals displays itself mainly in the cruel cunning with which they stalk their living prey. It resembles in quality the low
intelligence of the human criminal.

Personifications of great physical strength, intelligence, endurance, patience, gentleness, fidelity, affection and self-control, we find among the vegetarian animals. The beaver, the arboreal ape and the elephant are especially noted for their intelligence; deer, antelope and sheep for gentleness; the horse for its almost human intelligence, affection and fidelity; oxen, elephants and camels for their great strength and endurance.

**Meat is detrimental to the child in every way,** physically, mentally and morally. The poisonous acids and alkaloids which it contains clog the capillary circulation, causing anemia, coldness of the extremities and defective elimination through the skin. This results in congestion in the interior organs, high blood pressure in brain and heart, headaches, nervousness, irritability, tendency to fevers, inflammations and catarrhal conditions.

With the meat, the child often absorbs the eggs of worms, tubercular bacilli, and other parasites and disease germs. Certain forms of epilepsy, St. Vitus' dance and hysterical conditions are due to uric acid poisoning and to other pathogenic materials and ptomaines contained in flesh foods. Such patients, in times of crises, frequently emit pronounced odors of raw meat or uric acid. Strictly vegetarian diet, combined with other eliminative natural methods of treatment, cures the majority of these cases.

Most of these poisonous acids, alkaloids and ptomaines contained in the flesh of dead animals are powerful stimulants. I have frequently noticed that people who have abstained from meat for a long time, when they first partake of it again experience sensations and exhibit symptoms resembling those of alcoholic intoxication.

We have learned that these stimulating extractives of flesh foods chemically closely resemble caffeine, thein and nicotine. The use of one or more of these stimulants invariably creates a craving for the others. This explains why a heavy meat eater is usually a confirmed coffee drinker or inveterate smoker, and vice versa; and why we find it almost impossible to wean people from one of these stimulants as long as they persist in taking the others.

The legumes or pulses—peas, beans and lentils—are close seconds to meat in acid-producing qualities. Eggs contain considerable ready-made uric acid and a great deal of sulfur and phosphorus. These may become dangerous to the organism. For these reasons, meats, legumes and eggs are always danger foods for the child.

Children brought up on such foods will show the effects in nervousness, irritability, lack of self-control, craving for cigarettes and alcoholic stimulants. The most serious aspect of this question lies in the stimulative influence of meat poisons.
on the sex centers. It is a well known fact, verified by close observation, that flesh foods stimulate the sexual passions to a marked degree. This tendency is greatly increased by the use of coffee, tea and alcoholic stimulants in the form of wines, liquors or medicines. If the sensitive nervous organism of a child is overwrought by these powerful irritants, there can be but one result; precocious sexual awakening.

From the third year the child may gradually adopt with slight appropriate modifications, a diet as outlined under Sec. I, No. 10, and Sec. X, No. 7.

SECTION XL

Exercises in Infancy

1. Exercises in Infancy. Proper exercise is important from the very beginning of life. A baby will follow its natural instincts for exercise if allowed to do so, by working its arms and legs and writhing its little body in all directions, if not unduly hampered by tight clothing and bandages. A few nude air baths every day will afford excellent opportunity for baby's gymnastic stunts.

   After he is a few months old he may be placed on his stomach, when he will exert himself vigorously by trying to raise his head, to turn around, or to raise himself with his arms. He will soon learn to roll over and to creep lie nay now be pulled up gently by his arms and lowered again a number of times in succession.

   When three or four months old he may be lifted by one arm or by both arms; by the right arm and left leg, or by the left arm and right leg. When the baby is six or eight months old, he should be strong enough to rise from his back to a sitting position. This may be encouraged by holding down the feet. I have known a number of nature cure babies who at six months of age clung tightly to a stick while being lifted a few feet from the bed. Another good exercise greatly enjoyed by the youngsters is to roll them back and forth on a bed.

   The average healthy child will secure ample exercise while learning to walk and run and while playing with simple toys or with other children; but this may be supplemented to good advantage by special exercises devised by the father and mother. Nothing is better for the health and happiness of both parents and children than to join in merry romp and play.

   Between two and five years of age the child may be taught more difficult stunts, performed either by himself or with the assistance of the father or mother; but swinging the child high overhead, throwing him up and catching and other dangerous tricks should be avoided. They are risky and have very little effect in developing the body of the child. The best exercise at this age consists in outdoor play and games.
From the sixth year, the question of exercise becomes a more important one, especially since the children are confined for many hours in school rooms. If exercise at this time of life, through play and games and special gymnastics, is neglected, it may affect health, strength and efficiency of the child for life.

Those of good physique and ample strength may gradually take up and practice the exercises for adults outlined in sections XXI, XXII, XXIII, XXIV.

2. High Chair. A baby should not be put in a high chair until he is quite well able to hold the spine and head erect, and should never be left in a chair for any length of time. If a baby is forced to maintain a rigid, sitting position for a considerable time, before the bones and muscles are sufficiently developed, this may produce deformity of the spine. Maids and nurses, if not properly supervised, sometimes fasten a baby in a high chair and leave him there to take care of himself for long periods.

3. Toys. Since most babies have a habit of putting everything into their mouths, toys must be selected that can do no harm. They should have no paint, no sharp points or corners which might hurt the eyes or mouth, and must be of material which can be easily and thoroughly cleansed. Hairy and woolly playthings are unsafe, being unclean and germ carriers. Objects small enough to be swallowed must never be put within baby's reach. The simpler the playthings the better; a few clothespins, empty spools, or other simple objects are better than expensive toys.

SECTION XLI

Baby's Ailments

1. Hernia As a result of a weakly or sickly condition of the mother during pregnancy and of faulty prenatal management, many children are born ruptured. So far I have not known a single nature cure baby that was born ruptured. Such defects are due to weakness of the tissues. This results from mineral starvation. The tissue walls contain too much mortar (protein) and not enough building stone (mineral salts). Prevention of hernia, therefore, lies mainly in proper diet of the pregnant mother, but all the rest of the prenatal regimen described in these pages is of great importance in preventing this and other ailments and deformities.

There are three principal points at which rupture or hernia may take place in infancy-at the navel, in the groin, and at the line between the navel and the lower end of the sternum. Other kinds of ruptures are extremely rare.
2. **Umbilical Hernia** This is a protrusion of the intestine at the navel. It is the most common rupture in infancy. Pulling on the cord during childbirth, urging at stool or violent crying may result in rupture. The umbilical ring first expands and this forms a pouch into which one of the folds of the small intestine protrudes.

Treatment: Of primary importance is the diet as outlined herein. The baby must have plenty of fruit juices in order to reinforce the mineral salts in the milk. Cold bathing is very beneficial. The rupture itself should be cleansed several times a day with warm water. This must be followed by a wash with cold water mixed with lemon juice. Gentle, passive exercise, such as raising, lowering and twisting the limbs from side to side, also raising and lowering the body while supporting the shoulders and head, is of especial value.

The rupture must be reduced and kept from protruding by placing over it a large button or other article of similar shape, wrapped in gauze and held in place by broad strips of adhesive plaster. The adhesive tape is fastened over the button crosswise and must be applied in such a manner as to draw the skin from all sides over the rupture. Instead of the button, a compress made of gauze may be laid over the rupture and held in place by one broad adhesive strip. The covering of the rupture must be removed and renewed every day in order to allow cleansing, as before described.

When the child is old enough to exercise by himself, he should be taught special movements of the body and the limbs which develop the muscles of the abdominal region.

3. **Ventral Hernia.** This occurs along the middle line of the body between the navel and the breastbone, sometimes below the navel. The rupture may not be larger than the size of a pea or small marble, and may disappear on pressure. The treatment is the same as that of umbilical hernia.

4. **Inguinal and Scrotal Hernia** occur in infancy or in adult life; sometimes the inguinal canal does not close after the descent of the testes from the abdominal cavity into the scrotum, and the intestine descends through the open canal, thus producing the rupture. These forms of hernia become aggravated by coughing. They can be reduced immediately with gentle manipulation while the patient is lying on his back. This kind of rupture may be distinguished from hydrocele by the fact that in reducing it goes back easily with a gurgling sound. Hydrocele is not affected by coughing. A hernia is opaque to transmitted light; hydrocele, transparent.

These ruptures should be protected with a well-fitting truss. This has to be removed daily for cleansing of the parts. Appropriate exercises, passive and active, together with cooling sitz baths and washes with cold water and lemon juice are the best remedies for these, as well as of other forms of rupture.
5. Congenital Hernia occurs in the form of inguinal hernia and has to be treated in the same way. Ruptures of any kind must be reduced and properly supported. Constipation and consequent urging at stool may cause or aggravate any form of hernia and must, therefore, be overcome by the right treatment described under section XXVI, No.1.

6. Colic. This is usually caused by indigestion due to overfeeding, improper feeding, or too frequent feeding. The intestines are distended with gas, giving rise to a severe pain. The baby cries sharply, alternately drawing its legs up to the body and kicking them away. One of the quickest means of relief is a small enema of warm water and gentle circular massage of the abdomen from right to left. Food should be withheld until the symptoms have disappeared. The giving of milk or other food may quiet the attack temporarily, but the pain is apt to return with greater intensity. Warm water may be given if the baby will swallow it.

A baby managed in the natural way prenatally and postnatally is not likely to suffer from this ailment. Constipated babies are more prone to it than others.

Colic may also be caused by sudden chilling. In that case a warm bath for five or ten minutes, followed by gentle body massage will bring about a warm reaction.

7. Convulsions. These cause a great deal of anxiety to the fond mother. They are always reflex symptoms of some slight or serious internal disturbance due to wrong management. They commonly result from some form of auto-intoxication caused by digestive disturbances, and the resulting systemic or drug poisoning. An inactive condition of the skin, bowels or kidneys will favor auto-intoxication and convulsions. If proper care is taken to keep the system pure, and the organs of elimination in active condition, convulsions will not occur.

The best treatment during an attack is a quick, cold rub all over the body; application of a whole body or trunk pack; gentle soothing magnetic massage, and neurotherapy treatment. These treatments draw the blood into the surface and relieve congestion in the brain and nervous system.

8. Ailments of Teething. Many ailments of children are laid to teething, but this is a mistake. Well managed, healthy babies go through the teething period without any trouble whatsoever. This is practically always true of nature cure babies. When, however, the little body is heavily encumbered with hereditary and acquired morbid materials, food poisons and disease taints, the process of teething will not run its natural course and may precipitate any form of disease crisis.

When teething is difficult, it is frequently associated with digestive disturbances. Diarrhea may alternate with constipation and vomiting is of common occurrence. The baby may be restless and fretful. He tries continually to bite on something in order to facilitate the projection of the teeth
through the hardened gums.

No teething lotions or soothing medicines of any kind
should be given for the relief of pain in teething. They all
contain poisonous sedatives which benumb and paralyze the
nerves and have serious after effects upon the system. They
usually contain opium in some form, or other narcotic drugs.

The only way to prevent these and other infantile ailments is
to keep the little body as nearly normal as possible through the
natural treatment described in these pages. If this is closely
adhered to, it will prevent, in many cases, the development of
even measles and other common eliminative infantile
ailments.

During this critical period in the baby's life the diet must be
extra light; starchy food should be reduced to a minimum and
replaced by raw and cooked fruits and vegetables juices.
Cooling sitz baths will help to keep the bowels active and to
abate internal fever.

9. Acute Catarrhal Disease. Acute catarrhal diseases of
infancy such as croup, cold in the head, acute bronchitis and
whooping cough, are different forms of acute elimination
through which Nature tries to purify the little body from
hereditary and acquired accumulations of morbid matter,
systemic poisons and disease taints.

In accordance with this conception of acute diseases, as
purifying, healing efforts of Nature, we would not
do anything to check or suppress elimination but cooperate with
Nature in her purifying, healing efforts. How we do this has
been fully explained in other parts of this volume. (Section
VIII)

The natural treatment is very much the same in all acute
inflammatory ailments. Feeding must be reduced to a
minimum. If the baby does not insist upon eating, nothing
should be given except water with acid or sub-acid fruit
juices, such as lime, lemon, grape fruit and orange. If the
temperature does not run high, say not above 100 or 102 deg,
frequent ablutions with cold water at intervals of from one to
two hours will be sufficient to promote heat radiation and
elimination of morbid matter through the skin and other
organs of elimination. If the temperature runs' higher, say
between 102 and 105 deg, wet packs must be applied, and
renewed when they become hot or dry.

The wet packs are of especial value in all kinds of cough;
whether it be the ordinary cough, croupy cough or whooping
cough. A whole body or trunk pack, with or without a throat
pack, will give almost instant relief. In many instances where
baby is making the night hideous for the anxious mother, with
it's coughing, a well-applied whole body pack, or a
combination trunk and throat pack, will relieve the coughing
almost instantly, and induce restful sleep.
In serious cases it is always advisable to call in a natural therapist or some other drugless physician, if one can be reached.

The mother should not forget that all acute diseases, after they have once developed, must run their natural course. She must, therefore, not become impatient and lose faith in the natural treatment if it takes a week or more to cure a common cold in the head or an attack of bronchitis, or if it takes from two to eight weeks to cure a case of whooping cough. Serenity, patience and cheerfulness are the primary requisites of the nature cure physician.

PART IV

BABY BOOK

Natural Therapeutics has undoubtedly solved the problem of treating human ailments. All other schools and systems will in time have to adopt the natural way. It is the hub of the healing art; all therapeutic methods radiate from it like spokes from a wheel.

Natural Therapeutics, however, has something better to give than treatment of disease, and that is prevention of disease. If children were brought into this world in the manner ordained by Nature and reared in harmony with the teachings of natural philosophy, disease would soon be a thing of the past. Human beings would then enjoy good health and be as beautiful and perfect in their kind as are animals, which live in the freedom of Nature, guided by instinct and therefore in harmony with the laws of their being.

We must begin, then, with prevention, for prevention is always easier and cheaper, than cure. But where must we begin to study the prevention of disease? Some will say, "At birth, because that is the beginning of life." Not so: that would be too late. The mould is made and the foundation laid for health or disease, for happiness or suffering, for efficiency or deficiency, before the human being in process of creation sees the light of day.

"Then," it may be said, "we must begin with prenatal influence, for the physical, mental, emotional and moral habits of the mother influence powerfully the development of the new life she is carrying." True—but we must start earlier than that. The making of the human being begins with mating and conception. All subsequent development depends upon the right start.

SECTION XXXII

Heredity

1. Importance of Correct Mating. Of primary importance in the sacred rite of procreation, as already intimated, is mating. This should take place only between descendants of the same subrace, or of closely related subraces such as the Indo-Caucasian and Celtic.

If the racial descent of the marriage partners is so far removed that it has produced pronounced differences in racial
characteristic—as in the case of the swarthy Mexican and white skinned Englishwoman, or the dark eyed Magyar and blue-eyed Scandinavian—then procreation becomes miscegenation and degenerates into mongrelization of the offspring. Everywhere in the animal and human kingdoms Nature has set the mark of disapproval on the mongrel. The offspring of miscegenation is doomed to deterioration and extinction unless assimilation of the elements of a lower race by a higher takes place sparingly and gradually.

The law of racial purity may be summed up as follows: When a member of a higher race cohabits with a descendant of a lower race, the offspring of the union loses more or less the characteristics of the higher race and reverts in physical, mental and moral traits to the level of the lower race.

The constructive results of racial purity are evident in Hindus of the higher castes; in that portion of the Jewish race which in mating has faithfully adhered to the Law of Moses, and in the blond and blue-eyed remnants of the Indo-Caucasian and Celtic races in Northern Europe and North America. The destructive results of miscegenation are plainly evident in the mongrelized population of Mexico and everywhere in the half-breed and many kinds of mixed breeds. These usually fall below the physical, mental and moral standards of the parent stock, and almost invariably revert to the customs and habits of the inferior race.

2. Use Heredity. Use heredity deals with the transmission to offspring of acquired physical, mental and moral characteristics of the parents. According to this law as it has been formulated, the chances of the offspring for long life, health, mental efficiency and moral stamina, other conditions being favorable, are better in direct ratio to the advancing age of the parents at the time of conception. While this is contrary to popular opinion, which assumes that younger parents produce more perfect offspring than older ones, the fact of use heredity is proved, both in the animal and human kingdom, by common observation and statistical evidence.

The working of the law is based on the fact that the procreative elements of the parents, or rather the microzyma of those elements, cannot contain the impress of physical, mental and psychical characteristics which at the time of procreation were not developed in the threefold organisms of father and mother.

The age of the father at conception is called the "birth age" of the offspring and determines its birth rank. While the father and previous male ancestors, for reasons hereafter explained, seem to exert greater control over the mental and physical characteristics, the mother furnishes the nutrient soil for physical growth. This does not mean that she exerts no control over the mental and psychical characteristics of the offspring; in addition to her influence through use heredity she has added opportunities through prenatal influence and postnatal training.
According to this law, then, the chances of the offspring for excellent physical, mental and moral development become better as the age of the father at the time of procreation advances beyond thirty-five; while the physical condition of the mother for reproductive function is best below thirty-five years.

But we must not overlook the fact that too great a discrepancy of age between the man and woman may become the cause of physical and mental incompatibility, of aversion and great unhappiness, especially on the part of the younger woman.

Extensive statistical evidence seems to prove that the birth age of the mother has been of less importance than that of the father. As will be shown in Natural Eugenics, the majority of famous men in all lines of human endeavor had old male ancestors, while the mothers and previous female ancestors were of much younger age at the time of conception.

This may be accounted for by the following reasons:

The man is usually considerably older than the woman at the time of marriage. Men, as a rule, devote much more time and effort to acquiring a scientific, professional or business education than do women. This has been true in the past more than it will be in the future. Thrown early into the competitive struggle of life men generally have had to make greater mental and physical effort than have women.

These points are of considerable importance because it has been proved that it is not inherited brain mass and mental capacity, but strenuous and persistent effort that intensifies use heredity. The earlier this begins and the longer it continues before procreation takes place, the better the chances of the offspring for physical, mental and moral capacity.

The reproductivity of the mother has usually ceased at thirty-five. Though she be capable of childbearing a few years longer, usually conception has been avoided after that age. Men under favorable conditions remain reproductive to advanced age. Some of the world's greatest men descended from fathers over sixty years old.

That intellectual and creative capacity has followed the male line of descent rather than the female line, is indicated by the fact that the high intellectual capacity of many eminent men has skipped their daughters to reappear in male descendants. This may be partly accounted for by the fact that the daughters in their limited spheres of activity have not had the opportunity to unfold inherent intellectual capacity to any conspicuous degree.

There has been a tendency in some quarters to criticize the general entrance of women into professional and commercial life and to dilate upon the adverse influence this will have
upon womanly characteristics and family life.

In the light of the knowledge we possess upon the subject of use heredity, it is safe to say that any such problematical drawbacks will be far outweighed by the general postponement of the marriage age. This will insure not only better physical fitness but also higher intellectual development and greater moral stamina on both sides of parentage.

The tremendous benefits which this increased hereditary endowment will confer upon future generations cannot be overestimated. Greater intellectual and economic equality between the sexes will emancipate woman from degrading sexual subservience. Under the old order, sex appeal was too often her only stock in trade by which to attract and hold the male and thus to secure a living. Economic independence will insure greater consideration and higher esteem for the woman on the part of the man. It will go a long ways toward solving the problem of birth control in a natural way, by leaving it more largely to the judgment of the mother.

We find the law of use heredity according to birth age verified in the intelligence and moral development or obliquity of races, nations and tribes all over the earth—The lower the average birth age of a race or nation, the lower, other things being equal, the intellectual and moral development The greatest development and efficiency is found among those nations where marriage is delayed to a later age through custom, economic necessity, professional or military training.

The following quotation from "Control of Heredity", by Casper Lavater Redfield, is of interest in this connection:

"In general it may be said that wherever there are no restraints upon the sexual propensities, as with the Digger Indians, the Fuegians, the Andamanese, the Wauraus of the Guianas, the Bushmen and the tribes along the Gabbon river, there we find reproduction taking place at the earliest possible age, and the lowest grade of intelligence. Where we find some special circumstances or customs that delay the age at which reproduction takes place, as with the Patagonians, the North American Indian and the Polynesians, there we find considerably higher grade of intelligence.

"Where we find the custom of marrying late in life, as was customary with the Greeks and the Romans, there we find a very high grade of intelligence. And where we find a fortuitous succession of very late births, there we find the very great men of the world's history.

"In other words, the longer the time in which the individuals have in which to use, develop and strengthen their brains before reproduction begins, the greater and more powerful are the brains of their descendants."

In Volume IV of this Series I shall quote elaborate and
highly interesting statistics from Redfield, which reveal the effects of the various birth ages on physical, mental and moral characteristics. I shall confine myself, for the present, to the statement that, with few exceptions, the great artists, scientists, philosophers, statesmen and philanthropists were born from fathers whose ages ranged from forty to sixty-five years at the time of the procreation of their famous offspring.

The existence of these laws and principles as facts in nature is very evident in the training of racehorses and of other animals along certain lines of proficiency.

3. Pernicious Heredity. The effects of deteriorating and destructive heredity prenatal and congenital influences have been traced and commented upon in so many different ways that I do not believe it necessary to enter deeply into this phase of the subject. Various authors have filled entire volumes with the unsavory family histories of the descendants of the Jutes, Ishmaels and other drunkards, prostitutes, degenerates and criminals, which prove positively the transmission of morbid and pernicious traits through successive generations. It has been proved statistically beyond the shadow of a doubt that youthful delinquency, pauperism and criminality are the aftermath of immature marriages.

The laws of use heredity and prenatal influence, like all other natural laws and principles, manifest along opposite lines of expression. It remains for us to determine whether we shall align ourselves with their destructive or constructive activities. The effects upon ourselves and our offspring will show accordingly.

If I succeed in arousing the consciousness of prospective fathers and mothers to the glorious privileges and enormous responsibilities which these laws of nature confer upon them, then my labor will not have been in vain and I shall feel deeply gratified.

SECTION XXXIII

1. The Creative Alchemy of Love and Affection

Procreation—as is the case with everything else pertaining to the constituents and functions of the human entity—takes place on three planes of being, the material (physical and spiritual), the mental and the psychical planes. Which of these elements shall predominate in the offspring depends upon the mixture and adjustment of qualities in the triune makeup of the mating couple. In order to fulfill the law and to draw the divine blessing upon themselves and the fruit of their union the partners in the procreative function must be united by the bonds of love, or at least by the ties of true affection.
The source of creative genius is love and wisdom, and the essence of intelligence and power is sincerity and goodness. Without these, intelligence degenerates into selfish cunning, power into self-destructive brute force. The spring cannot rise higher than its source; its water cannot be pure and wholesome when contaminated by impure admixtures from filthy surroundings.

It is not generally known that use heredity pertains to intellectual and psychical qualities, as well as to the physical material. Animalism breeds nothing but selfish animalism. The vampire who craves and absorbs the love of its victims and robs them of vital energy, without being capable of feeling or bestowing affection, is the child of a discordant union—of brute animalism on the part of the man, of secret aversion and hatred, usually, on the part of the woman. These bestial and degrading tendencies on the one side, and unrequited love craving on the other, breed sex perversion, and propagate the harpies who delight in the seductive power of superficial beauty, while gloating over the weakness and ruin of their victims.

True love and affection, paired with intelligence and goodness; liberate the creative elements necessary to the production of perfect offspring.

The finer qualities of mind and soul open the fountains of life on the higher planes, liberate and harmonize the male and female procreative fluids, and charge them with the purest and most potent intellectual, spiritual and psychical elements.

The divine fire of creative genius burns only in the love aura of truly mated couples. It is true that these are rare under our artificial, unrighteous social institutions, and that accounts for the rarity of complete manhood and womanhood.

Perfect offspring, endowed with beauty and power of body, mind and soul, destined to shed through life a radiance of health, happiness and helpfulness—to love and be loved—issues only from the union of love and affection with intelligence and goodness.

"Love lieth at the foundation" (of all that is). "Love is passion, enthusiasm, affection, heat, fire, soul—God."

To the extent that love enters into the holy rite, to that extent its attributes will be absorbed in the threefold organism of the woman and become active in the child building in her womb. While she loves her man more than ever, her most passionate affection is centered in the new being in process of development. On it she bestows the purest and best in her food and drink, in her thoughts, emotions and secret desires. Fear, worry, anxiety, jealousy and hatred are strangers to her soul; these are the emanations of the lower spheres—she lives in heaven.

Somebody endowed with deep insight into these matters has
said:

"Whatsoever male and female shall truly will for, hopefully pray for and earnestly yearn for, when love pure and holy is the nuptive ascendant, in form, passionate, affectional, divine and volitional, that prayer shall be granted, and the boon be given—but the prayer must precede."

What are the direct effects of the marital rite upon the participants? If the sex attraction operates on the physical material plane only, if lust instead of love presides at the matrimonial feast, then temporary gratification of erotic craving will be followed inevitably by monotony, satiety, gradual revulsion and aversion, culminating in a morbid craving for change and variety. The partners in carnal self-indulgence are intuitively aware of these tendencies to marital unfaithfulness, and, therefore, easily dominated by distrust and jealousy.

The procreative function is attended by complete satisfaction, buoyancy of body and mind and lasting happiness only when sex attraction operates on the higher and highest planes of being, as well as on the lower; when desire and impulse are operative on both sides. Thus only will the generative function fulfill its sacred purpose and confer the highest possible benefits upon parents and offspring.

The woman, being the more highly sensitized, must be responsive to the call of holy passion. To force unwilling compliance will ruin the woman, kill her love and curse her offspring. Balzac says: "He who begins with his wife by a rape is a lost man." It is impossible for a wife to love unless she is won, not forced to compliance.

2. Sexual Intercourse During Pregnancy. Sexual intercourse should be considered the most sacred function of the human entity. From the highest and best viewpoint it should be exercised only for the propagation of offspring. However, considering the present stage of ethical and moral development, temperate indulgence may not be wholly condemned. Excessive intercourse is always weakening and harmful to both participants. We must remember that the sex fluid is the carrier of the life force. It is that which constitutes strength, resistance to disease, initiative and genius. During abstinence from intercourse the sex fluids with their creative energy are absorbed through the inguinal glands into the organism and increase physical, mental, moral and spiritual capacity and energy.

Set rules for frequency of intercourse cannot be given. This must depend entirely upon individual conditions. One safe rule is that after indulgence there should be no feeling of satiety, weakness and exhaustion. The more frequent the indulgence the stronger will grow the power of habit and of passion and the greater will become the abnormal craving. It is the same with all other appetite and passions. The more frequently they are indulged, the stronger they grow, until
they attain complete control and develop into destructive habit

A free and confidential understanding in regard to these matters between those who contemplate matrimony would go far to prevent marital misery. A great deal of unhappiness arises from the fact that mates in the matrimonial union often labor under misapprehensions concerning the attitude of each toward the sex relation, and are prevented by excessive sensitiveness and delicacy from frankly discussing it. (For further discussion of this subject, see page 390, Volume I.)

There is no problem of married life that needs more thorough mutual consideration and understanding than this one. Lack of it accounts for a great deal of "incompatibility," loss of love, revulsion, hatred, and the final tragedy in the divorce court.

Among animals, no female allows intercourse after conception. In this respect as in many others, man has sunk below the natural standards of the animals. No greater crime can be committed against the woman and the unborn life.

It is a sad commentary on our system of education, scholastic as well as religious, that our young people are not instructed before and after marriage in these all important laws of Nature. To do this should be the province of the priest who unites them in marriage, or of the family physician, if the parents have failed in their duty.

It is well known (notwithstanding the denials of medical skeptics) that the unborn infant may be "marked" by transitory impressions, especially by strong emotions; that even insignificant parental characteristics are reproduced in the offspring. Is it any wonder, then, that the most powerful of human emotions should leave its impress on the growing brain and sex centers of the fetus, causing abnormal and precocious sex consciousness?

All too often is sex perversion born and bred in bone and flesh, before the child sees the light of day. The mother cannot be blamed for this "slaughter of the innocents"; she has not been instructed on the subject. Though she intuitively senses the horror of it, she submits, in order to maintain her hold upon the man—and many a life is thus cursed before it is born. The fault lies primarily with those of the medical profession who teach our young men that the free indulgence of sexual passion is not only legitimate, but a necessity to manly vigor.

This dictum of pseudo-science is almost universally concurred in by spiritual guardians. No greater lie was ever promulgated from the blackest abyss of Hades. If our young men were taught that greater happiness is to be attained by the exchange of tender affection than by the indulgence of the coarser animal appetites, that the creative forces thus preserved develop and strengthen their own finest capacities
of body, mind or soul, they would wisely and chivalrously protect mother and child, at the same time conserving their own physical and moral integrity.

In no other way is it possible to call forth the deepest gratitude and unfailing esteem of a true woman. Many a man whom we have thus advised has become a lifelong friend in consequence.

3. Limitation of Offspring. I believe that the unlimited production of offspring, encouraged in some quarters for swelling the ranks of religious bodies or for increasing tax paying and cannon-fodder material, is a misfortune, both to the family and to society. Limitation of offspring, in accordance with the means and circumstances of the parents, is not only justified but should be encouraged. In any case, the production of offspring entails great responsibility upon the parents and if they cannot properly comply with the needs and rights of their children, they fail in their responsibility and duty.

Any method, however, which interrupts intercourse or prevents conception in an artificial way, is absolutely to be condemned, because this has very harmful and positively destructive effects upon the physical, nervous and mental organism of those who thus try to cheat nature by the suppression of a natural process. In our professional work we frequently meet the victims of such pernicious practices. The ordinary contrivances for prevention make of intercourse something akin to masturbation. This is also true of intercourse without orgasm which is strongly advocated under various guises. The use of poisonous antiseptics and germ killers in warm water douches is not essential for prevention, and is highly injurious. These chemicals have a tendency to poison the sexual organs and to produce in time atrophy, many kinds of female disorders, and tumors. Undoubtedly the greater number of so called female troubles and malignant tumors in later life are caused by curetments, antiseptic douches and the use of poisonous drugs, for producing abortion. The only legitimate methods of birth control are abstinence or common cleanliness.

There is nothing more conducive to the physical, mental and spiritual health and development of a woman than childbearing and child rearing in harmony with Nature's laws, as outlined in these volumes. Under favorable conditions it is not a thing to be dreaded, but to be looked upon as the greatest of blessings and opportunities in the life of a woman. Natural philosophy and practice takes these problems of progeneration, childbearing and childrearing out of the domain of uncertainty and haphazard management with its dire consequences, and makes eugenics the most exact of all sciences and the sublimest and most enjoyable of all the arts.

4. Determination of Sex. Numerous theories have been advanced concerning this interesting subject. Many attempts have been made to wrest from Nature the secret of sex
determination and numerous more or less ingenious methods have been recommended for sex control.

I know of one method only which seems to have a rational basis and which has proved of practical value. Observations seem to prove that the right ovary liberates male ova only, while the left ovary discharges female ova. The two ovaries discharge ova only at alternate menstruations.

With this data at hand, it is possible to determine the sex of a child after one birth has taken place. Suppose the first child was a boy. By consulting our pregnancy table (page 377) we can determine when the last menstrual discharge took place. This menstruation liberated a male ovum; the next menstruation would liberate a female ovum, the next a male, etc.

Thus, using the last menstruation period before the last conception as a fixed point, it would be possible, figuring from period to period, to determine the sex nature of the ovum to be discharged at each following menstrual period. Account is taken of all regular periods during the time menstruation is suspended in pregnancy. Thus, conception may be timed in such a way as to impregnate at will a male or female ovum.

This solves in a simple, rational manner another of Nature's riddles, namely, the reason for the practically equal division of the sexes.

SECTION XXXIV

Prenatal Influence

There exists just as much diversity of opinion among scientists concerning the reality of prenatal influence as about race heredity, use heredity, disease heredity and many other mooted problems of science and philosophy, which we shall study in Vol. IV of this series. In the following I shall present and examine impartially the various theories and opinions concerning prenatal influence; then we shall be better prepared to draw our own conclusions.

1. Medical Science Denies Prenatal Influence. Medical men, as usual cocksure of the correctness of their theories and hypotheses based on the "latest discoveries", deny and ridicule the possibility of prenatal influence, and relegate it to the rubbish heap of popular superstitions. They base their judgment on the fact that no nerves pass from the body of the mother through the umbilical cord into the growing fetus in the placenta, which forms the soft protecting nest of the new life within the womb. They claim that since no direct nerve connection exists between the two, mental and emotional vibrations cannot be transmitted from the brain of the mother to the brain and nervous organism of the fetus.
Are there no other means of communication between the mind of the mother and the brain of the unborn!

In the volume dealing with Eugenics we shall learn how universal intelligence and creative will become individual intelligence and personal will.

Cosmic vibrations do not flow into the gray matter of the human brain over coarse physical nerve tracts. They come over the psychical wireless which connects the human soul with the world Soul, the individual intelligence with the universal or cosmic intelligence the human will with the divine will.

Since, as proved by modern brain and nerve anatomy, immaterial cosmic intelligence and "power to will" fashion the brain of the mother into physical material centers for the expression of human intellectual faculties, capacities and powers, why cannot these cosmic vibrations act in like manner over the psychic wireless through the soul and mind of the mother on the brain and nervous system of the fetal organism?*

These epoch making discoveries and revelations of modern brain anatomy are explained in Vol. IV of this Series, Natural Eugenics—Man Building on the Physical, Mental and Moral Planes.

Why should the wireless, which transmits impulses of intuitive intelligence from the great source of all intelligence and creative energy into the soul of the mother, cease to operate at that point, and fail to transmit its message to the brain and nervous system of the fetus which is most intimately related and connected with the organism of the mother?

What about the phenomena of hypnotism? Absolute control of the subject's mind, through the intelligence and will of the hypnotist does not depend upon the existence of an umbilical cord and physical nerve connection between the two. The hypnotist, by silent command, may call his subject from a distance, far beyond the reach of his voice.

People telepathically attuned may communicate in like manner, spontaneously, or by conscious intent. Why then should we doubt the possibility of vibratory correspondence between the mental and emotional conditions of the mother and the plastic nervous organism in process of development within her womb?

If a complexity of sound can impress itself permanently upon the wax cylinder of a phonograph, or what is still more marvelous, if the photographic rays of passing scenes can be fixed and retained in the picture film, why should it be impossible for the mental and emotional vibrations of the mother to impress and modulate the molecular and cellular constituents of the fetal brain and nervous organism?
I have compared this creative power of the mother mind to the process of electrotyping. As the particles of metal in suspension in the fluid adhere to the spoon that is to be coated with silver, so the atoms and molecules in the gray matter of the brain of the fetus group themselves in harmony with the thought forms and emotional vibrations of the mind and soul of the mother. While this mental and psychical electrotyping takes place automatically, the mother's brain and nerve molding power can be greatly strengthened and intensified by the conscious and voluntary operation of the psychical wireless that establishes vibratory oneness between her and the human entity in process of development within her own body.

Thus it is revealed how a brain prenatally refined, organized and fashioned may endow the nascent individuality with certain aptitudes and talents along established paths of cerebration. There surely will be less resistance along such lines of physical, mental and moral endeavor than along other lines not prenatally influenced and molded. Therefore I strongly advise mothers, pregnant with new life holding marvelous possibilities for good or evil, not to be influenced by the superficial reasoning of materialistic science, but to follow the sacred intuition and impulse of their own creative genius in this, the most holy function of their being. Every normally constituted mother is intuitively aware of this wonderful power, and is willing and anxious to exercise it when her consciousness has been aroused to the great possibilities and responsibilities which the divine privilege of motherhood confers upon her.

It is natural for us to admire a great artist who portrays the human form, true to life, on the painted canvas, or who fashions it from inanimate stone, metal or marble; how much more grand and godlike is the creative power of truly mated parents whose privilege it is to bring into the world, and to fashion according to their highest ideals, a human being endowed with life and intelligence, with the infinite possibilities of a new center of creative activity.

Yet many mothers, totally ignorant of their divine creative privileges and possibilities, victims of physically and morally degrading marriage relations, and often filled with secret aversion or open hatred for their marital companions, pass unwillingly through pregnancy and not infrequently seek to destroy the new life. When the unfortunate victim of such marital incompatibility, conceived in passion and developing under the worst possible influences of mental and emotional discord, comes to arouse the maternal instincts of affection and devotion, then fear, anxiety and worry, like a continual nightmare, haunt the unhappy mind of the mother and impress their discordant vibrations upon the sensitive films of infant consciousness.

Compare this condition of fear, apprehension and gloom in the mind and soul of an unhappy and unwilling mother, with the joyful and ecstatic state of mind of a mother conscious of
the creative power of her intelligent will, who, from the time of mating and procreation, with accurate prescience prepares the most favorable conditions, astrologically, prenatally and postnatally for the finest development of the physical, mental and moral characteristics of the future world citizen.

The loftiest exaltation of a creative genius working in dead clay and cold marble cannot approach the ecstasy of a mother who has acquired a knowledge of the great laws which make possible the development of a perfect human being,—the embryo of a master, an angel, a being destined to be godlike in its faculties, capacities and powers!

In place of fear and anguish of soul, what joy to the mother who knows that it lies within her power to prevent disease and degeneracy in her offspring; that the development of the child depends solely upon her own intelligent effort! Nothing is left to accident. Child bearing becomes an exact science, the most beautiful and inspiring of all arts and professions Under such conditions motherhood, instead of being the greatest of hazards and hardships, becomes a divine privilege and the highest achievement of human existence and endeavor. It falls short only of the creative work of the great Universal Intelligence whose instrument of creation is the mother.

2. An Example from History. Let us consider the oft-quoted example of Napoleon Bonaparte. His mother, Lutitia Bonaparte, while pregnant with the future military genius, accompanied her husband on a military expedition, sharing with him the hardships and excitement of camp life, and the marches and battles of a military campaign. If there be nothing in prenatal influence, is it not singular that Napoleon should have become one of the greatest military geniuses of all ages, while not one of his many brothers ever exhibited enough military ability to make an efficient corporal? What was it that favored or determined the birth of the great military prodigy under these circumstances? The ancestors of Napoleon's father were not professional soldiers, nor was the father especially interested in military matters before the conception of his gifted offspring.

The dominant influences, therefore, must have operated through the singular occupation and surroundings of the mother during this particular pregnancy.

Many similar striking examples have been cited in works on prenatal influence. I myself might add many convincing proofs from an extensive experience in medical practice; but time and space do not permit. Contributory evidence may be secured from many excellent works dealing with this vital problem in human life. I may be permitted to say that use heredity and prenatal influence are distinctly manifest in the physical and mental characteristics of our three children who were born at intervals of seven and five years. Each one of them clearly mirrors in his or her physical, mental and emotional peculiarities the predominant mental tendencies, occupation and surroundings of the parents during the
respective prenatal periods. Similar manifestations of prenatal influence may be observed in almost any family.

3. Birthmarks. Medical men of late deny also the possibility of "marking" the offspring by sudden fear or shock on the part of the mother during pregnancy. Incidents of this kind, however, are of such common occurrence that it is a waste of time to refute these flippant denials.

There are good reasons for believing that such marking is more likely to occur during the periods when the menstrual flow should take place, but is suspended.

It may be argued that to mention the possibility of marking to a pregnant woman will greatly increase the probability of electrotyping violent emotions upon her offspring; in other words, that the fear of the thing will help to materialize it. This may be true to a certain extent, but we must remember that sudden shock through fear or disgust may cause the mischief anyway, whether or not the expectant mother is aware of the possibility. Understanding a danger and being prepared for it seems the best protection. The pregnant woman should study carefully section XXX, dealing with mental and emotional causes of nervous diseases, and should learn to relax to any sudden surprise and thus neutralize unpleasant and fear arousing impressions. Self-control is the royal remedy and the key to mastership.

4. Physical Influence. Now that we have studied some of the more important hereditary mental and psychical prenatal and postnatal influences, let us see how the physical condition of the mother's organism influences the brain and nerve matter of the fetus in its last stages of development, and after birth.

Materialistic science teaches that brain matter exudes thoughts and feelings, as the liver excretes bile, or the stomach pepsin. Natural science proves that mind is superior to matter, that the new born ego, by the power of intelligent volition, must fashion in the gray matter of the brain the molecular groupings or centers for the expression of intellectual and emotional activities, such as language, music, numbers, scientific and philosophic speculation.

This means that active cerebration and brain molding do not begin until after birth. But it stands to reason that the work of the nascent intelligence may be greatly facilitated or impeded by the physical condition of the brain. It is reasonable to assume that intellectual and emotional vibrations will more easily shape the gray matter of the brain into new configurations when it has been prenatally refined, organized and developed along certain lines of cerebration by use heredity and by constructive prenatal influences.

There exists a remarkable similarity between the brain molding and memory building activities of the intelligent ego and the making of phonographic records and moving picture
films. Lifelike impressions of sounds and passing scenes can be made upon the phonographic and photographic mediums only when wax and film are in a highly refined and plastic condition. When impure of substance and coarse of texture they, are not sensitive and plastic enough to register and retain the subtle and highly complex vibrations of sounds and passing scenes. In order to receive and register a great variety and complexity of sounds, the wax on the phonograph cylinder must possess a certain degree of refinement, softness and plasticity. If it is too hard and coarse it registers the loud and coarse sounds only. Such a record cylinder, exposed to a beautiful symphony executed by a great orchestra, would register and reproduce only the shrill cries of the trumpet, the rattle of the snare drum and the booming of the big horns and bass drums. The softer sounds of string, wood and wind instruments and finer shadings of tone and rhythm would be lost. With increasing refinement and plasticity, more subtle and delicate sound vibrations will be retained and reproduced.

In like manner the sensitive gray matter of the cortex of the brain must be in a pure and plastic condition in order to receive and register the impressions and impulses coming through the sensory organs, the psychic intuition and the intellectual and emotional activities of the mind. Anything in the way of physical impurity or foreign matter that tends to clog the brain, or to feed it with waste and morbid materials, or with corroding poisons, will lessen the atomic and molecular motility of brain and nerve matter, and will interfere with, or impede, the groupings and subtle transformations involved in the fashioning of brain centers through mental and emotional influences.

If the nutrient blood which feeds the brain substance of the fetus be saturated with CO$_2$, the benumbing, paralyzing carbon-dioxide, with clogging uric acid or the destructive acids of phosphorus and sulfur, the gray matter cannot, respond to the subtle and complex impressions and impulses from without and within.

The purity or impurity of the plastic matrix of the cortex depends upon the materials absorbed from food and drink. If these are so constituted as to create in the system excessive amounts of clogging and corroding substances, then these food and drink poisons will have a benumbing and deteriorating effect upon the sensitive gray matter of the brain, as well as upon the coarser tissues in the joints, muscles and vital organs. There is a rheumatism of the mind as well as of the joints.

A brain asphyxiated and clogged with pathogenic materials cannot be alert and active; it is too dull and lazy to think; it would much rather sleep than work; it is incapable of doing its best when its tiny blood and lymph vessels are obstructed with waste and morbid deposits which prevent the oxygenation and drainage of its delicately organized cellular tissues.
This, of course, is true postnatally as well as prenatally. A brain originally capable of the highest and finest achievements of the human mind may become utterly worthless, and may degenerate into idiocy through food, drink and drug poisoning.

Medical men tell mothers they need not worry over prenatal feeding, because the placenta, the vascular bag which forms the nest of the new life, acts as a filter which purifies the blood before it reaches the fetus. Common sense and every day experience tell another story. Even the best in the blood of many mothers is bad enough to serve as food for the new life.

The placenta does not filter out of the blood of the mother all food, disease and drug poisons. This is proved by the wretched condition of many infants, suffering from malnutrition, anemia and rachitis, after delivery. If the vital fluids of the mother are deficient in the mineral elements, or in other important nutritive substances, how can they deliver them to the fetus?

Occurrences like the following, quite common in our institutional practice, prove positively that the placenta is not a perfect filter for systemic poisons and for disease taints circulating in the blood of the mother.

One of the most pitiable cases of eczema in a little child less than one year old we traced to the fact that the mother, during her first year of marriage, had traveled with her husband through Eastern European and Asiatic countries, and during her pregnancy had been vaccinated five times while passing through localities where smallpox was prevalent. Both she and her husband had always enjoyed perfect health. The family record was excellent as far as traceable; still the body of the infant soon after birth, was covered with open bleeding sores, presenting a revolting sight. We could find no explanation for this strange phenomenon other than the many vaccinations during pregnancy. These had contaminated the blood of the mother, and through her the body of the fetus, with a filthy scrofulous taint.

The baby suffered terribly. For many months it slept but little, because of the excruciating pains. The eczematous eruptions were of a very stubborn nature; they broke forth again and again. Finally, however, after eighteen months of natural treatment, we succeeded in purifying the little body of the horrible infection. The child is now a little over three years old, in perfect health, and during the last twelve months has shown no signs of the morbid taint.

Under another section I shall describe the influence of food upon character and sex life.

To recapitulate: Purity, plasticity and motility of the highly refined and sensitive materials which make up the gray matter of the brain depend upon pure food, plenty of fresh air and exercise, and upon all other natural methods of living.
1. Conception takes place whenever the male spermatozoon joins the female ovum (egg) within the woman's womb. Normally the female organism liberates from its ovaries but one ovum each month, usually during menstruation, while the male discharges millions of spermatozoa at each orgasm.

Conception does not always follow copulation. The ovum remains in the womb and is capable of impregnation for about five days after menstruation. The spermatozoon on entering the womb may meet an ovum which has been discharged at a previous menstruation, or it may remain alive in the womb for a number of days and finally come in contact with a newly discharged ovum at the following menstruation.

The spermatozoon retains its ability to impregnate the ovum for from ten to fifteen days after its discharge into the womb. When the male and female germs merge into one another, conception or impregnation takes place. As soon as this has happened, the impregnated ovum becomes attached to the inner lining or mucous membrane of the womb and begins its new life as an embryo. The period comprising the time from the impregnation of the ovum until the beginning of labor or childbirth is called pregnancy.

The table of pregnancy on page 377 indicates the probable date of normal termination of a pregnancy, calculated from the last menstruation.

2. Exercise During Pregnancy. Unfortunately a great many expectant mothers labor under the idea that they must rest and be relieved from work and exercise. This of course is a great mistake. Light housework is good exercise. There is nothing more harmful during pregnancy than nursing "that tired feeling" by lounging idly about the house and coddling one's real or imaginary aches and troubles.

Of great benefit to the pregnant woman are all outdoor sports such as tennis, golf and other games which require vigorous exercise without straining or overworking the body. The great benefit of walking and other outdoor exercises, aside from their general invigorating effects, lies in the strengthening of the abdominal muscles and ligaments, which at delivery will greatly facilitate expulsion of the fetus.

The walk should be brisk and rhythmical, body erect, head thrown back, chest forward; the breathing at the same time should be deep and regular. These walks should be continued as long as time and endurance permit. Nothing, of course,
must be pushed to the point of exhaustion. One good long
walk every day is necessary; two are better.

We all understand the necessity for a plentiful supply of
oxygen under ordinary conditions, and especially in time of
illness. During pregnancy the demand for oxygen, as well as
for mineral salts, is doubled or trebled on account of the needs
of the rapidly developing organism in the womb of the
mother.

These extra demands for oxygen and ozone must be
supplied by systematic deep breathing, cold bathing, outdoor
walks, etc. If circumstances do not permit the taking of
outdoor exercise, deep breathing should be practiced as often
as feasible, at the open window.

Next in importance among gymnastic exercises is the
internal massage described under section XXI, No.16.

Those exercises are especially valuable which bring into
play the abdominal muscles and the muscles and ligaments of
the genital organs.

3. Clothing. Clothing and the manner of wearing it
profoundly influences the normal or abnormal development of
the fetus, the health of the mother, labor and delivery.

At no time should the waistline be constricted by a corset or
even by the ordinary skirt band. All clothing should be as
loose and light as possible—one-piece under and outer
garments, with the weight suspended from the shoulders, are
best. If skirts are worn they should be fastened to skeleton
waists of some thin cotton material. The close, heavy texture
of the material from which the corset or so called "reform
waist" is made is injurious because it interferes with skin
elimination.

Even the slightest constriction of the waist line interferes
with the free circulation and the normal blood supply to the
abdominal organs, which is of especial importance in
pregnancy; it also hinders the free expansion and movement
of the uterus during the various stages of pregnancy.

Within the waistline are located a dozen or more important
vital organs of the body. Any sort of constriction compresses
these organs and pushes them out of their normal position.
While this is extremely injurious to the body of a woman
under ordinary conditions, it is doubly so to the pregnant
mother and to the rapidly growing fetus. Undoubtedly many
deformities and monstrosities are produced by unnatural
constriction of the blood vessels and vital organs in the
abdomen and pelvis of the pregnant woman.

If due attention is paid to the foregoing influences, labor
and delivery will be brief and easy. This we have proved in
hundreds of cases which have come under our management.
The reason why women of civilized countries spend many
hours and sometimes days in dreadful agony of childbirth while those of primitive or savage races, as we call them, produce their young easily and painlessly as the animals do, is that primitive women live more simple and natural lives, while "civilized" mothers violate practically every law of Nature in their daily habits of living.

Civilization unfortunately stands in many respects for that which is artificial, unnatural and therefore productive of disease and suffering in all domains of life, not only as regards physical health, but social and political health as well.

SECTION XXXVI

Danger Signs During Pregnancy

1. **Dropsical Swelling.** Swelling of the limbs and distention of the veins of the legs during pregnancy may be caused by a tendency towards varicosity, intensified by obstruction of the circulation due to the enlarged uterus. Such a condition requires, aside from the natural regimen, careful and competent treatment.

   Swelling of the limbs or other parts of the body may also be caused by incipient or advanced Bright's disease. The urine should be examined from time to time, especially if there is a swelling of the feet and ankles, or if there are dropsical symptoms in other parts of the body.

   Such dangerous conditions are usually brought about through the excessive intake of starchy and protein foods which overwork the liver and kidneys and cause pathogenic dogging of the capillary circulation. This may result in uremia attended by violent and sometimes fatal Convulsions.

2. **Uremia** is the result of retention in the system of waste materials and poisons that should be eliminated through the kidneys and skin. Medical treatment for such conditions, aside from the administration of stimulating drags, consists in hot bathing with the idea of opening the pores of the skin.

   We understand that all hot water treatment gives only temporary relief and is followed by greater enervation and inactivity of the skin. The best water treatment for systemic poisoning of any kind consists in the application of wet packs followed by cold ablations as described in section XV.

   The addition to the packs, dry friction rubs, air bath, good massage and neurotherapy treatment will aid in restoring the normal activity of skin, bowels and kidneys.

   Whenever the urine contains sugar or albumen, fasting, alternating with raw food diet, is indicated. Suitable regimens are outlined in sections X, XI.
The giving of heavy food to the mother with the idea of increasing the flow of milk is all-wrong. We have found in all cases that the diet outlined in section X will produce a more copious flow of rich milk than lie "nourishing" meat diet. The best remedy for a scanty flow of milk is slow and thorough mastication of a few spoonfuls of raw crushed wheat every day.

3. Morning Sickness. One of the common disorders experienced during pregnancy is that known as Morning Sickness. One suffering from this ailment, though following a natural diet, should sip a cup of hot postum while remaining in bed. If this does not have the desired effect and if the patient has not been accustomed to drinking coffee, half a cup of black coffee with a few drops of lemon juice will quiet the irritated nerves. It is necessary after taking the hot drink to remain in bed for at least thirty minutes. It is understood that this is only an emergency measure. If continued, it will lose its good effect and work injury.

SECTION XXXVII

Labor and Delivery

At about forty weeks, exactly nine solar months, from the period of conception the fetus reaches full maturity, and labor begins. Labor is divided into three stages. During the first stage the neck of the womb becomes slowly and gradually distended and the orifice of the womb opens widely. When this has taken place, the fetal membranes burst and the amniotic liquid surrounding the fetus escapes.

During the second stage the fetus emerges from the womb.

After expulsion of the fetus, the placenta is expelled from the uterine cavity. This constitutes the third stage of labor.

The first stage usually begins with more or less radiating pains in the abdomen, accompanied by dull pain in the small of the back and a drawing pain in the limbs. Sometimes women with the first baby feel these pains weeks in advance of the actual commencement of labor. At first they occur at long intervals and are of short duration, but gradually become more prolonged and more frequent. The pains are due to a cramp-like contraction of the muscular apparatus of the uterus forcing its contents downward.

Under this pressure from above, the neck and mouth of the uterus distend to their limits, and the walls become thinner and thinner. First the inner, then the outer orifice of the neck of the womb opens and the fetal membranes protrude and finally rupture, allowing the amniotic fluid to escape. Shortly after this the part of the fetus nearest the orifice, normally the
head, makes its appearance. At the present time the average duration of the first stage of labor is six hours, but it may last twenty-four hours or longer, depending upon the plasticity and elasticity of the bony structures of mother and infant, the rigidity of the cervix, and the vigor or lack of vigor of the muscular apparatus of the uterus.

While the foregoing is true of the average delivery under ordinary ways of living, we find that after the enforcement of a natural regimen of living during and, better still, before pregnancy, the entire period of labor and delivery does not cover more than half an hour, or at the utmost from one to two hours. Even the disadvantages of slight build and smallness of pelvis can be overcome by the natural regimen outlined in section X. When our youngest child was born, the mother gave the first sign of pain at about midnight. I rose from bed instantly, but had not time to finish clothing when the membranes broke. Within twenty minutes after the commencement of labor the infant was resting in my hands.

The wife of a prominent lawyer in a western city had experienced three difficult deliveries. Each time surgical instruments had to be used and she had suffered untold agonies lasting from 24 to 36 hours. When she became pregnant the fourth time the most prominent physicians in her home city assured husband and wife that it was not safe for her to go through another delivery, that the womb was in worse condition than ever before therefore they recommended surgical removal. For conscientious reasons, however, the husband and wife did not follow the advice of the doctors, but decided to try natural methods of treatment.

The lady placed herself under our care during the fifth month of pregnancy. From that time on she followed strictly the natural regimen of living and received daily the usual hydropathic and manipulative treatments. This was continued until a few weeks before delivery. In this case the baby was born within an hour from the first contraction, and the mother of the patient, who was in an adjoining room, had not heard a sound. Many similar experiences refute the idea that it is unsafe and injurious for pregnant women to undergo the ordinary methods of natural treatment, such as hydropathic sprays, sitz baths, massage, Swedish movement and other forms of manipulation.

1. Preparation for Delivery. The diet during the last week before the beginning of labor should be very light, consisting mostly of fruits and vegetables. From the commencement of labor no food at all should be given, until at least twenty-four hours after delivery; a three-day fast is better.

In addition to a competent physician, a nurse or midwife should be engaged. If a good neurotherapist, who has had sufficient experience in obstetrical work, can be procured, he should be preferred, because he can assist delivery and make it much easier by manipulative treatment.
The nurse will make the necessary preparations and provide the various supplies needed in labor. With the first sign of approaching labor, the physician in charge should be summoned. A rectal enema of one pint or more of warm salt water (See. XVIII, No.4) should be administered. The woman should be given a vigorous cold rub and her genitals thoroughly cleansed. She may then remain on her feet and walk about, comfortably dressed, until actual labor commences.

2. No Anesthetics. The attending physician should not be impatient to hasten delivery with drugs or instruments. The use of anesthetics should be avoided insofar as this is possible. They should be employed only when absolutely necessary—that is, when excessive pain must be allayed or when surgical delivery is unavoidable.

3. Breaking of Water Bag. When the bag of water is about ready to break, the patient is placed in bed. Premature discharge of the amniotic fluid must be guarded against. An escape of the liquid at an early stage means difficult and prolonged labor, commonly known as "dry labor". Usually the membranes burst when the orifice is fully dilated. A large sponge is held in readiness to catch the out-flowing liquid.

3 a. Umbilical Cord. When the infant has been delivered, the umbilical cord should not be severed at once. Plenty of time should be allowed for the blood to transfuse itself from the body of the mother to that of the child. This is important. If the connection is severed too soon, the child begins life in an anemic condition.

The newborn baby usually greets the world with a lusty cry. It should be placed on its right side with its face turned away from the mother, care being taken that the cord is not stretched tight. As soon as the cord stops pulsating, plenty of time being allowed for blood transfusion, it is tied about two inches away from the baby's abdomen and cut a little above the ligature. The baby is now wrapped in a warm blanket and put in its crib.

4. After Delivery. Immediately after the baby is born, the nurse or attending physician gently compresses the abdomen and womb of the mother, kneading and rubbing it occasionally in order to secure complete contraction and thus prevent hemorrhage. After delivery the mother enjoys a period of rest and recuperation which usually lasts for about half an hour.

5. Afterbirth. Meanwhile the placenta becomes detached, and when the pains set in again a few contractions usually suffice to expel it with all the membranes.

The attending physician must make sure that none of it is left in the body, since this might result in putrefaction of the remains and blood poisoning. The woman's genitals should be washed with clean sterilized water.
The exhausted woman should now enjoy a deep, wholesome sleep and awaken from it in a few hours refreshed and strengthened.

In the foregoing I have not gone into the details of obstetrics and of technical management because this must be left to a competent obstetrician. I have called attention only to those points which are of special importance from the viewpoint of Natural Therapeutics and to the differences in treatment between the conventional and natural methods.

6. The Lying-In Period. The lying-in period varies from five to twelve days, according to the constitution of the mother and the care that she has taken during pregnancy. The greatest danger of the lying-in period is puerperal sepsis or blood poisoning. This condition is the result of infection occurring during labor, or it may result from the retention of parts of the placenta.

The only way to prevent this is by observing the most scrupulous cleanliness during the entire process of childbirth and during the lying-in period. When blood poisoning has developed it must be treated the same as all other acute inflammatory diseases (see section IX).

7. Care of the Newborn. The child should begin to breathe immediately after the cord is cut. If it fails to do this, the physician should lift the baby by its feet to facilitate the escape of mucous from the trachea and throat. If necessary the mucous must be removed from the throat by the insertion of the little finger, or by means of a tiny stick covered with gauze.

Breathing may be accelerated effectively by a few sharp taps on shoulders and buttocks. If this fails to bring the desired result, artificial respiration must be resorted to at once. The attendant grasps the child by its shoulders, its head resting between his palms and the two index fingers being hooked under the child's armpits. It is now swung between the physician's legs and lifted high above his head so as to be turned upside down. This is repeated from fifteen to twenty times, after which it is placed in a basin containing a few inches of warm water. Its body should then be rubbed briskly with cold water.

Father Kneipp used to take the newborn babe by the nape of the neck and the feet and submerge it quickly in cold water. This, a few times repeated, is probably the quickest way of resuscitating an asphyxiated baby.

In order to soften the cheesy deposit which frequently covers the body of the newborn, it is well to rub the skin with warm olive oil. After the greasy covering has sufficiently softened it may be removed with bits of gauze. This is followed by a cleansing bath with warm water and castile soap.
After the warm cleansing bath, the little body should be quickly rubbed down with cold water, wrapped in a soft, warm blanket and laid away to sleep until it wakens of its own accord. A normal baby should sleep for about twelve hours, and must not be disturbed to force food on it before it is ready to take it.

8. Bathing. From the first day, the baby must have a morning and evening bath. This consists, as before described, in a quick, cleansing bath of warm water and castile soap, followed immediately by a brisk cold rub. In the course of a few weeks the baby can be placed, for the cleansing bath, in a small bathtub containing a few inches of warm water. Immediately after the cleansing bath the warm water is replaced by cold water. This is taken up in the hollow of the hand and briskly applied to the little body. In this fashion the child, within a few months time, will enjoy its cold rub just as much as an adult. I have seen several such nature cure babies, but a few months old, object most vigorously to a warm bath. The cold rub is the best preventive of chilling; but care must be taken that the temperature of the room where the bath is given is not below 70 deg.

The olive oil bath or rub, often recommended for premature babies or infants suffering from malnutrition, is very injurious, because it occludes the pores of the skin and prevents the elimination of poisonous gases and other morbid materials from the body. The skin is not an organ of digestion. Olive oil, like all other foods, must enter the body through the alimentary canal where, under the action of digestive ferments, it is broken down into its component elements which are then assimilated through the intestinal membranes. Oil absorbed through the skin is not digested, and it circulates in the body as foreign matter which in this state cannot be assimilated and utilized in the system.

9. Powdering after the bath is fully as injurious as the rubbing with oils or massage creams. Powders and creams tend to clog the pores, and most of them contain poisonous antiseptics which lower the vitality of the skin and prevent or suppress elimination in the form of skin eruptions, eczemas, etc. For chafing use nothing but cold water. In case the chafing should become unusually severe and painful, through neglect by the caretaker, a soothing and healing lotion composed of one part lemon juice to two parts olive oil, may be applied a few times, until the irritation is under control.

10. Air Baths. Next to cold water, there is nothing that will invigorate baby's skin and nervous system as will the air and sun bath. If the season will not allow the outdoor air bath, the baby should be allowed to lie nude several times a day, for thirty minutes or more, in a warm, well ventilated and sunny room.

11. Constipation. Glycerin and suppositories should never be used; neither laxatives nor cathartics. Oat extract and cooling sitz baths will produce natural movements.
12. Diarrhea is a form of morbid elimination, and must never be suppressed by drugs. If it is habitual, bailey or wheat extract prepared in the same manner as oat extract, is a good remedy. If the diarrhea is persistent and of a violent nature, no food at all must be given, except water with dilute acid fruit juices, until the purging ceases. Even then plenty of time must be allowed for the rebuilding of the sloughed intestinal membranes.

13. Bandages. Until the umbilical cord dries up and falls off, it is necessary to cover the navel with a gauze compress dipped in olive oil. This is held in place by an abdominal bandage made of soft cotton material. These strips should not be hemmed, merely torn or cut. They should be drawn just snugly enough to hold the compress in place, but not tightly enough to interfere with circulation. The, navel must be cleansed and the compress renewed twice each day. After the umbilical cord has dropped off we no longer apply the abdominal bandage. This is contrary to common usage, but is the best practice. The abdominal bandage overheats the body and interferes with the free movement of the diaphragm and the circulation of the blood.

14. Clothing. The clothing of the infant should be loose and light and as simple as possible. Freedom of movement is very important; binding or pressure upon any part cannot help but interfere with the circulation, and otherwise produce injurious results. The clothes should be short, in order to allow the feet and legs free play. Light weight, porous cotton materials are best for both under and outer garments. A lightweight wool petticoat may be worn when absolutely necessary to provide sufficient protection for the baby. Cotton hose and bootees may be used, but under no circumstances should such articles be of wool, because it prevents free elimination from the skin. The baby's head should not be covered out of doors, except in severe weather. At no time should a veil be placed over the face, as it will cause the infant to reabsorb the poisonous exhalations from its own lungs. All clothing should be changed each day. No garment should be starched—such a practice is not only useless but harmful.

15. Diapers must be provided in sufficient number to allow thorough cleansing and drying. The wet diapers should be scalded in hot water and very thoroughly rinsed in several waters afterwards. They should then be dried in the open air and sunshine. Soiled diapers must be well washed and boiled. Washing powders, soda, ammonia and other chemicals should never be used. They have an extremely irritating effect upon the delicate skin of a baby. In order to save labor and to facilitate the cleansing of the diapers, small squares of clean old linen or muslin rags, or pieces of absorbent gauze, may be placed inside. These inserts will absorb all or most of the bowel movement and may then be burned. If the skin is irritated or chafed, the parts should be sponged off with clean cold water at each change, paying special attention to cleansing of the genitals. Oils or powders must not be used to soothe the sore places, because they clog the pores and
16. **A wet nurse** is to be preferred to artificial feeding. She should be thoroughly healthy, not over thirty years of age, of equitable temper, not excitable or nervous and her diet should be that prescribed for the mother.

17. **Care of the Nipples.** They should be thoroughly cleansed before and after nursing; not with carbolic acid, but with water and dilute lemon juice. The lemon juice tends also to harden the nipples. Treatment of the nipples may begin before the birth of the child.

18. **Care of the Eyes.** The baby's eyes, whether awake or asleep, should always be shielded from strong light, either sun or artificial, and from dust and wind. The eyes should be washed with cold water after every cleansing bath. If they show any tendency to weakness or disease, slight vibratory massage over the closed eyelids should be given after the cold eye bath.

19. **Care of the Mouth.** A healthy baby's mouth needs no cleaning before the arrival of teeth. As a matter of fact, the teeth of a perfectly healthy adult would not need cleaning any more than do those of an animal living in the freedom of nature. The saliva is a sterilizing fluid, under normal living, intended by Nature to keep the mouth clean and healthy. Cleansing of the mouth of an infant with the finger or with a cloth may injure its delicate membranes. If the mouth must be washed, in case of disease, a swab made by twisting a piece of sterilized absorbent cotton on the end of a smooth stick should be used. The swab should be dipped in warm boiled water, and the interior of the mouth washed thoroughly, the cotton then being burned.

20. **Care of the Ears.** The external ear should be cleansed with a soft rag or swab as before described. Never use a hard instrument inside the ear.

21. **Care of the Nose.** A baby's nose should be cleansed as a part of the daily toilet, in the same way as the ears. A swab may be made by twisting a, piece of gauze to a cone. As soon as the child becomes old enough, it should be taught to sniff up cold water through the nostrils and the nasal passages. This is the best way to keep the nasal membranes in a clean, healthy condition.

22. **Care of the Genital Organs.** The genital organs of both sexes must be kept scrupulously clean with as little handling as possible. The foreskin of the penis of the male baby should be drawn back at bathing time and the organ thoroughly cleansed, always finishing with cold water.

23. **Phimosis.** The treatment of phimosis is fully described under Sec. XXVIII, No.1.

24. **How to Lift the Baby.** The best way to lift a young
baby is to slip the left hand under the back beneath the shoulder, spreading out the fingers in such a way as to support the neck and head. Then lift the feet and legs with the right hand. **Never lift an infant without first supporting the spine.**

When a baby has grown strong enough to hold up its head and has gained considerable strength in the muscles of the back and neck, he may be lifted by grasping him with outspread fingers under the armpits; the body must be held firmly so that the entire strain does not come on the shoulders. A baby should never be lifted by the arms. This may dislocate the shoulder joints.

### SECTION XXXVIII

**Prenatal Feeding**

1. **Effects of Diet During Pregnancy.** The problem of infant nutrition begins before birth. Prenatal feeding determines the physical start in life. On it depends not only the condition of the mother's health during pregnancy, but also the size and weight of the fetus, pliability of the bony structures, ease or difficulty of delivery, and the quality of the mother's milk.

   The fleshtier and heavier the newborn infant, the prouder and happier are the parents and the doctor. Yet, excessive size and weight of the child constitute the most prominent cause of difficult and painful childbirth and frequent necessity for instrumental delivery.

   The biblical saying, "In sorrow thou shalt bring forth children"; has led many to believe that woman's dreadful suffering is a necessity, God ordained; but is not man's ignorance, rather than the cruelty of an avenging God, to blame?

   This latter view is confirmed by the fact that other mammalia literally cast their young, without pain or difficulty; and the labor pains of primitive mothers are insignificant, their delivery presenting little more difficulty than that of the lower animals. A squaw on the Western Plains stops a few hours by the wayside to deliver her papoose and then resumes her journey as though nothing had happened.

   Women among the European peasantry, who wear no corsets, live on black bread and vegetables, and have plenty of exercise in the fields and in the home to the last day of pregnancy, have their babies without help of midwife or physician and resume their usual routine of work within a few days after delivery.

   Thousands of mothers who have adopted natural ways of
living have learned to dispense with anesthetics and the surgeon's instruments; they now bring forth their offspring without excessive pain.

2. Results of Faulty Diet. It is significant that the offspring of the lower animals, at birth, consist of little more than skin and bones, while the newborn human is often abnormally large and fat. This is especially true of babies born of weak and anemic mothers. As before stated, excessive size and weight of the infant is not a matter for congratulation, but is a pathological condition. It indicates fatty degeneration of the fetus, due to the anemic watery condition of the blood of the mother, and the cause of this hydremia of mother and child lies in the faulty dietetic habits of the former.

The ordinary diet of American women consists almost entirely of meat, fish, fowl, potatoes, white bread, pastry, coffee, tea and refined white sugar. The few vegetable, which enter into the daily dietary are first deprived of their all important organic salts by faulty cooking; fruits are looked upon as luxuries and frequently are regarded as harmful.

The anemic, watery condition of the blood of mother and child is not due to a lack of starchy, protein and fatty materials in food and blood, but to a deficiency of organic mineral elements. Neither is the anemic condition, as the regular school of medicine assumes, caused by lack of iron. Any ordinary food mixture, as well as the blood and milk of anemic mothers, usually contains a sufficient amount of iron. The actual cause of the anemia is a deficiency of other mineral elements.

As I have explained in Volume III of this Series, carbonic acid poisoning and the resulting sluggishness of the surface circulation, coldness of the extremities and congestion of the inner organs is not caused so much by a lack of the oxygen-carrying iron as by a deficiency of the carbonic acid neutralizing and eliminating sodium and magnesium.

If the blood is deficient in lime, phosphates, silicon and fluorine, rachitic conditions, softening of the bones, deformed spines and legs, and decay of the teeth, are inevitable results.

It is an easy matter to supply the daily needs of the organism for proteids, starches, fats and sugars; the difficulty lies in supplying a sufficient amount of the organic mineral elements.

The deficiency of sodium in human blood, Dr. Lahmann proved in the following table of comparative blood analyses. In a hundred parts of ash he found in the

The percentages of lime and of other positive mineral elements in the human blood are also much lower than in the blood of cows, oxen and sheep.

While the blood of cattle and sheep raised on pasture is very uniform in composition, hardly any two samples of human blood are alike. It is for this reason that Dr. Lahmann adopted cow's milk instead of human milk as the standard elementary food combination.

In the following table, he compares the percentages of minerals in the ash of cow's milk with the percentages of mineral elements in the ash of various other food materials.

A daily dietary consisting largely of meats, eggs, white bread, potatoes, peas and beans, though excessively rich in proteids, fats and starches, will, on account of its deficiency in sodium, lime and magnesium, inevitably result in carbonic acid poisoning, anemia, rachitis, premature decay of the teeth and a multitude of other acute and chronic ailments.

If, however, the daily dietary contains a liberal amount of green vegetables and fruits, a normal food mixture resembling that of cow's milk can easily be obtained. It must be remembered that fruits and vegetables are not only rich in the most important mineral salts, but that they are relatively poor in proteids and carbohydrates.

For this reason fruits and vegetables facilitate the establishment of an equilibrium between proteids and carbohydrates on the one hand and organic mineral salts on the other.

3. Excessive Fat Formation. We can now understand why the ordinary faulty diet of pregnant mothers causes anemia, softening of the bones, sluggish circulation, carbonic acid poisoning and fatty degeneration in mother and offspring.

Lack of sodium causes excessive accumulation of carbonic acid, and oxygen starvation. This results in defective
Defective draft prevents the complete consumption of coal, and chokes the furnace with the products of imperfect combustion. Similarly, lack of oxygen in the tissues (due to carbonic acid poisoning) causes an incomplete combustion of food materials and waste products, resulting in fat formation and in the generation of poisonous byproducts.

Lack of sodium also prevents the neutralization and elimination of uric and other acids and ptomaines (pathogenic matter) which accumulate in the tissues, block the circulation and assist in the smothering of the vital processes.

In order to eliminate these pathogenic materials, there arises an abnormal craving for water—"the anemic thirst"—which is closely related to the thirst of fever patients and of diabetics. Excessive water drinking is encouraged by the popular "flushing" fad.

To make things worse, the anemic, for reasons before stated, usually suffers from weak heart action and sluggish circulation. This means defective elimination of water through the skin and kidneys, resulting in a watery (dropsical) condition of the tissues and fatty degeneration.

Not all anemic, carbonic-acid-poisoned mothers, however, develop a tendency to obesity. On the contrary, under certain constitutional conditions, they may become exceedingly lean, like the anemic, carbonic-acid-poisoned consumptive. Briefly stated, sluggish heart action and weak kidneys favor retention of carbonic acid and water in the tissues and thus make for fatty degeneration. Good circulation and normal activity of the kidneys may keep the system free from excess of water and carbonic acid, but excessive proteids in the diet may result in sulfuric and phosphoric acid poisoning. These destructive acids break down the tissues, rob them of their mineral constituents, and thus cause excessive loss of flesh and fat.

In both types of dysemia the blood of the pregnant mother is overloaded with poisonous gases, waste matter and the debris of broken-down tissues. The oxygen supply to the fetus is therefore very much impeded and we find that both fleshy and lean mothers produce babies of abnormal size and weight, ranging from eight to twelve pounds, while the normal weight of the newborn should not be more than six pounds.

4. Advantages of Natural Regimen. We know of many instances where mothers, after having given birth to heavy, fleshy babies, in subsequent births have reduced the weight of the new born to normal, and the pain of delivery to a minimum, by the adoption of a natural diet, plenty of exercise in the fresh air and systematic deep breathing.
The effects of a natural regimen are manifested in various other ways. The bony and muscular structures of mother and child are much more pliable and elastic, making parturition and delivery much easier. Pure blood, normal nutrition and abdominal exercises, walking and special gymnastics, greatly strengthen the abdominal and uterine muscles, thus facilitating expulsion of the fetus.

The morning cold rub, systematic deep breathing and general exercises, every day outdoor walks and right mental and emotional attitude are all of paramount importance in the regimen of pregnancy.

The Regimen for Wholesome Living, section I, is admirably adapted for all the needs of the pregnant mother.

SECTION XXXIX

Postnatal Feeding

Thanks to the educational influence of nature cure propaganda, a decided change for the better in baby feeding has taken place during the past ten years. Up to that time the "top cream mixture" was universally recommended by allopathic physicians and given to babies by trained nurses.

While in the meantime many physicians and nurses have adopted more natural methods, the "top cream mixture" is still too common and must be entirely abolished in order to safeguard the health of our little ones.

In the February, 1909, issue of the Nature Cure Magazine, I commented upon this subject as follows:

1. Bottle-fed Babies. Our food analyses disclose the interesting fact that the elementary composition of the ash of the milk of an animal is about the same as the composition of the ash of its body.

They also show that good cow's milk when normal comes closer to the requirements of the infant body than does inferior human milk.

Our tables of food analyses show that chemically the composition of cow's milk and of human milk is very much the same. Human milk contains a little less proteid and a little more sugar than cow's milk, and the latter is much richer in organic salts than the former. There is much more of the all-important sodium in cow's milk than in human milk and about twice as much calcium (lime) and iron (table p.100). This explains why rachitis is so common among babies, while never found among calves.

As we have learned, the elimination of poisonous acids
from the body depends on sodium. The building of the bony structures depends on lime; the oxygenation of the blood, on iron.

Many years of practical experience in the care of babies has convinced me that milk fresh from a healthy cow is greatly to be preferred, as nourishment for infants, to the impoverished milk of scrofulous mothers.* In this connection it is significant that one-half of all "civilized" mothers, thanks to unnatural food and drink, vaccination and poisonous drugs, are incapacitated for nursing their offspring.

* This may not be true in the future if our milk cows continue to be regularly subjected to tuberculin tests.

To one who has studied the comparative analyses of cow's milk and human milk, it is incomprehensible why the former, when given to infants, should be diluted and spoiled by large quantities of water, salt, soda and inorganic mineral lime (in the form of lime water).

This procedure, however, is still frequently recommended by physicians of the regular school. Undoubtedly, the great frequency of anemic and rachitic diseases, the darkening of the iris, appearance of scurf rim, and the signs of catarrhal conditions in stomach and bowels are caused by such unnatural feeding.

The following extracts are taken from an article entitled "Bottle-fed Babies", in the Ladies' Home Journal. It was written by Dr. Emelyn Lincoln Coolidge, of the Babies' hospital, New York. Thousands of mothers, on account of the high standing and excellent reputation of this family journal, undoubtedly have followed, without question or misgiving, the advice presented.

The formulas given below are for the average healthy baby, and are called "cream" or "top milk" mixtures.

"Food for the first month. With a spoon, or a tiny dipper which comes for this purpose, carefully skim off the top six ounces from a quart bottle of milk; to this add twenty-four ounces of water which has been boiled and cooled, and in which has been dissolved three teaspoonfuls of granulated or six of milk sugar; next add a pinch of bicarbonate of soda and a small pinch of salt; mix this all thoroughly, and pour enough for each feeding into ten separate bottles& Then cork the bottles family with cotton and either Pasteurize the milk or stand it on the ice.

"For the second month. Skim off six ounces of cream, then pour off three ounces of milk; add twenty-four ounces of water and the same amount of sugar, salt and soda as above; mix and bottle.

"For the third and fourth months. Cream, six ounces; milk, six Ounces; water, twelve ounces; barley or oatmeal gruel, twelve ounces; sugar, salt and soda as usual, etc.

Plain Milk Formulas

"Pour the entire quart of bottled milk out into a clean pitcher and then back into the bottle several times, thus thoroughly mixing the milk; then take:
"For the first month. Six ounces of milk, twenty-four ounces of barley-water, half a tablespoonful of granulated or one of milk sugar, a pinch of bicarbonate of soda; mix all well together and pour the proper number of ounces into separate bottles, and either Pasteurize or place on ice.

"For the second month. Nine ounces of milk, twenty-one ounces of barley-water, one tablespoonful of sugar, and a pinch of soda."

Physicians would never think of giving such advice as this, if they were acquainted with natural dietetics founded on exact and complete analyses made by food chemists of the nature cure school.

I have already called attention to the fact that food chemistry, whether practiced in allopathic colleges, in great sanitariums or by vegetarian food reformers, deals with proteids, starches, fats and sugars only, and leaves entirely out of consideration the all-important mineral elements or organic salts of potassium, sodium, iron, lime and magnesium.*

*This was true at the time this article was published in the Nature Cure Magazine.)

On these five positive mineral salts, as we have shown, depend all the important vital functions of the human organism, while proteids, starches, fats and sugars serve only as building and fuel material.

The digestion of the proteid and carbohydrate foods, as well as the elimination of the waste matter resulting there from, depends upon the positive organic mineral salts.

Study carefully these recipes for baby feeding, taken from the Ladies' Home Journal, and compare the mixtures with the analyses of cow's milk and human milk in the accompanying tables.

Let us consider the "top milk" mixture, prescribed for the first month. The cream rising to the top is almost pure fat. The all-important mineral elements plus the nourishing milk sugar and proteids remain in the skimmed milk, which is looked upon as worthless and fed to the pigs.

Our food analyses (see tables in Volume III, Cook Book) show that the ordinary brands of flour are almost devoid of mineral elements. Furthermore, one teaspoonful of barley to one pint of hot water does not mean much in food values. Where in these six ounces of cream (fat) and twenty-four ounces of barley water is baby to get the necessary amount of sugar for fuel material, of proteid for tissue-building, of lime for bone-building, of iron for oxygen-carrying, and of sodium, magnesium and potassium for the processes of elimination?

It seems that these deficiencies are intended to be overcome by baking soda, mineral table salt and the lime water, so generally prescribed by physicians. Many times I have demonstrated that inorganic mineral salts, with the possible exception of a little table salt, should not enter the animal or human organism, that these salts must first be organized,
made alive in the plant or animal cell, before they are wholesome food for animals or human beings. I have shown that, taken habitually in the mineral form, these salts accumulate in the human body, act as irritants and poisons and reveal their presence in the iris of the eye.

I fail to understand why the tender and sensitive organism of the newborn infant should be encumbered with inorganic minerals while cow's milk contains them in ideal form, made alive first in the grasses and grains, then still more highly organized and magnetized in the body of the animal.

It is bad enough to give mineral sodium, lime and table salt to an adult, but it is little short of criminal to give them to babies under the guise of foods and medicines.

The cream mixtures are readily digested, because there is not much to digest. The fact that infants thus fed cry for food continually is good evidence that their needs are not satisfied. Babies fed with this sort of slop grow fat for a while. The watery food inevitably produces fatty degeneration. This for a season swamps the little body with unhealthy fat. But the first crisis which happens along often takes away not only the unnatural fat, but the baby also.

The artificial mixtures contain entirely too much water in proportion to nourishing elements. The resulting malnutrition and the constant irritation caused by the inorganic minerals result in chronic diarrhea or constipation.

The Right Way

The best food for the newborn and growing infant is undoubtedly the mother's milk, provided that she is herself in fairly good health. Unfortunately, many mothers are unable to nurse their offspring, and if a healthy wet nurse cannot be secured, other food must be provided.

The best substitute for human milk, without question, is cow's milk, fresh, pure and undiluted, as it comes from the animal.

"Why", indignantly exclaims the trained nurse, when we give these instructions, "undiluted cow's milk is altogether too rich, it is indigestible for baby; if the milk is not boiled or pasteurized, germs and bacilli will surely create infectious diseases".

To this we answer: Our analyses show that the difference in composition between cow's milk and human milk is not enough to affect the infant. The danger lies not so much in overfeeding on "rich" cow's milk as in underfeeding on watery milk and cereal dilutions, and in poisoning the little body with inorganic minerals.

As regards germ infection and the necessity for pasteurizing the milk, the menace to health and life is greater through
malnutrition than through germs and bacteria. Germs we cannot escape, not even if we were surrounded on all sides by walls of air-purifying and antiseptic materials.*

*Since the foregoing was written we have learned that low vitality and morbid soil will develop perfectly normal microzyma into so called disease germs.

One of the foremost French bacteriologists claims that in the mouths of infants shortly after birth he has found almost every disease bacillus known to medical science.

William Osler; M.D., to whom the English language is indebted for the verb "to oslerize," says in The Principals and Practice of Medicine on page 151, in the chapter on Diphtheria:

"The presence of the Klebs-Loeffler bacillus is regarded by bacteriologists as the sole criterion of true diphtheria, and as this organism may be associated with all grades of throat affections, from a simple catarrh to a sloughing, gangrenous process, it is evident that in many instances there will be a striking discrepancy between the clinical and the bacteriological diagnosis."

In the first part of this sentence he states that bacteriologists regard as the sole criterion for the diagnosis of diphtheria the Kiebs-Loeffler, or diphtheria, bacillus; in the last part of the sentence he admits that this bacillus is found in even slight catarrhal conditions, and he might add that it is found just as frequently in the mouth and throat of healthy infants and adults. This is a good example of "orthodox" scientific reasoning.

If germs and bacilli of themselves could destroy health and life, the human race would in a short time become extinct. Disease germs are omnipresent. They permeate the tissues of our bodies and in the intestinal tract swarm by millions. Whether they prevail depends upon natural resistance, or reserve force, and upon the disease soils in the system. The air we breathe is saturated with all sorts of disease germs or their microzyma.

Since baby cannot escape germ invasion, the real problem is how to increase the resistance of the little organism and how to purify it of morbid matter so that disease germs will not find anything to feed on.

Resistance depends largely upon proper nutrition. Diluted, watery milk, contaminated by inorganic minerals, is not a good nutrient; its nutritive value is still more reduced by pasteurizing or boiling. Heating milk or any other proteid food above 1500 F. coagulates the albumen, disorganizes organic compounds, precipitates salts and dissipates the life elements. This reduces the nourishing value and digestibility of the milk.

Nature does not provide the young animal with boiled or
pasteurized milk, and we should not lower food values by such methods.*

* It is now admitted that pasteurization and boiling kills "newly discovered vitamins" which are the "life elements" constantly referred to in my earlier writings.

I do not wish to intimate, however, that scrupulous care and cleanliness should not be exercised in the selection and handling of the milk.

Wherever possible, secure the milk of a single healthy cow that grazes on green pastures or is fed on normal clean food mixtures. Milk from cows kept in stables and fed on brewery and distillery slops and other refuse should not be used.

Every vessel and utensil with which the milk comes in contact must be carefully scoured, submerged in boiling water, drained and kept in a light, airy place.

The nursing bottle, after each feeding, must be taken apart and carefully scrubbed, inside and out, in hot water with an addition of a little soda. It should then be left in pure, cold water, until the next feeding time.

2. When to Feed. Physicians quite generally recommend feedings at stated hours, in fixed quantities.

This is altogether wrong, it establishes at once the stuffing habit, does not permit the development of natural desire and its regulation. The infant very soon becomes accustomed to eating at certain times, whether it really needs the food or not.

Food should not be given until there is an actual demand for it, which will express itself in real hunger. By careful observation and experiment the mother will soon learn to distinguish the ordinary crying of the baby and the desire for food expressed by it. If this practice of feeding only when there is a natural desire for food is strictly followed, the infant will soon establish its own regular feeding times, usually at intervals of about three or four hours in the daytime. The stomach digestion of a feeding of milk will require about three hours, therefore a minimum of that much time should be allowed between feedings after the first few weeks.

If the mother can nurse her baby, it should be put to the breast upon awakening from its first sleep, either before or after bathing and dressing.

The first secretion of the breasts (colostrum) is not really a food, but performs an important function in cleansing the intestinal tract and preparing the digestive system to properly digest and assimilate the milk when it comes, usually about the third day.

3. How to Feed. If artificial feeding must be resorted to, no food at all should be given, except a few teaspoonfuls of water, during the first twenty-four hours after birth. During
the next few days, cow's milk should be given, well diluted—about one-half milk and one-half filtered or boiled water. From week to week the amount of water should be reduced until at the end of the second month the baby takes cow's milk undiluted.

4. Night Feeding. In the nighttime feeding should not be encouraged. During the first four months it is advisable to feed not more than once during the night. After that the child should be weaned from the habit entirely. This will be facilitated by giving a drink of water instead of milk.

5. Amount of Food. Discretion should be observed in determining the amount of food. Do not induce the baby to take as much as possible, rather as little as possible. Its welfare does not depend upon the amount of food consumed, but upon the amount which it can easily digest and assimilate.

When more food is given than the digestive organs can take care of, the entire mass may ferment and sour.

6. Grain Extracts. If undiluted milk proves too rich, grain water may be added. In order to prepare this, take clean grain as it comes from the field, crush it in a hand grain mill or a new coffee mill, take three tablespoonfuls of the crushed grain to one pint of cold water, and boil on the stove for one hour; or in the fireless cooker for two or three hours, in which ease use a little more water at the start. While the gruel is boiling over the fire, add enough water to allow for evaporation and absorption. When thoroughly cooked, strain the gruel through a fine cloth or sieve. Add one tablespoonful, or more if necessary, to each milk feeding.

When baby is constipated, add to the milk, grain extract made from oats, and frequently cool the bowels with cold water. This will cure the most stubborn constipation. If the bowels are too loose, add to the milk, extract made from barley or wheat.

The small particles of hulls in the grain extracts improve digestion and evacuation, in a mechanical manner. They permeate the curds and keep them from coagulating too solidly, thereby facilitating the penetration of digestive juices; they also exert a mild stimulation on the walls of the intestines, thereby increasing the peristalsis of the bowels and evacuation of feces.

7. Baby's Natural Medicines. Fruit juices and scraped raw ripe pear or apple and the pulp of cooked fruits such as prunes or figs without addition of sugar or sweetening of any kind, are baby's finest medicines. They increase the supply of organic salts for blood, nerve and bone building and for purposes of elimination. They are nature's own chologogues, laxatives, tonics and antiseptics. They keep the little body sweet and wholesome. All babies under our care receive fruit juices beginning with the second week.
During the first two months, give one teaspoonful of orange juice, grape fruit juice or prune juice, one hour before or after each nursing. After the second month, gradually increase the amounts of fruit juices and begin to add raw pear or apple scraped with a spoon or dull knife, or the mashed pulp of fully ripened peach or grapes.

8. Weaning the Baby. Nursing infants should be weaned from the breast after the eighth or ninth month. From the sixth or seventh month, both nursing and bottle-fed babies should begin to take some solid food. The best of these to begin with are whole-grain cereals, gruels, raw and cooked fruits and tender vegetables in small amounts. Mealy baked potato is one of the best foods, better than the cereals.

9. Feeding After First Year. After the lapse of the first year, the solid foods are gradually increased and the milk reduced in quantity. Eggs should not be given before the eighteenth month, then soft-boiled or poached. During the second and third year half an egg twice or three times a week is sufficient; after that an egg at a time may be given once or twice a week.

Meat and all other foods prepared from the dead animal carcass are bad enough for adults, but it is inexcusable to give them to tender infants and children.

Dog fanciers, when they sell a valuable canine, usually advise the buyer not to give the animal any meat before the second year, lest it become a victim of distemper; and dogs are naturally meat eaters.

Well informed physicians now generally advise not to give meat to children before the fifth or sixth year. They have learned this much from the nature cure people.

Foods undoubtedly have a powerful influence, not only on the physical body, but also on the mentality and the emotions. These problems will be interesting subjects of investigation for the food chemist and psychologist of the future. In general, we may say that flesh foods are stimulating and feed the passional nature, while fruits and tender vegetables refine and stimulate brain and nerve matter as well as the intellectual, emotional and spiritual activities. Cereals, nuts and pulses build and repair the physical body and supply the body with heat and muscular energy.

The majority of animals adhere strictly to one kind of food, and therefore faithfully exhibit in their mental and emotional characteristics the effects of different food materials. Ferociousness we find personified in the carnivorous bulldog, lion, tiger and panther (that is why soldiers are fed on meat three times a day); gluttony and omnivorous voraciousness in the hog, chicken and hyena; cold-blooded cunning in the fox, and cruelty in the cat. The intelligence of the carnivorous animals displays itself mainly in the cruel cunning with which they stalk their living prey. It resembles in quality the low
intelligence of the human criminal.

Personifications of great physical strength, intelligence, endurance, patience, gentleness, fidelity, affection and self-control, we find among the vegetarian animals. The beaver, the arboreal ape and the elephant are especially noted for their intelligence; deer, antelope and sheep for gentleness; the horse for its almost human intelligence, affection and fidelity; oxen, elephants and camels for their great strength and endurance.

**Meat is detrimental to the child in every way**, physically, mentally and morally. The poisonous acids and alkaloids which it contains clog the capillary circulation, causing anemia, coldness of the extremities and defective elimination through the skin. This results in congestion in the interior organs, high blood pressure in brain and heart, headaches, nervousness, irritability, tendency to fevers, inflammations and catarrhal conditions.

With the meat, the child often absorbs the eggs of worms, tubercular bacilli, and other parasites and disease germs. Certain forms of epilepsy, St. Vitus' dance and hysterical conditions are due to uric acid poisoning and to other pathogenic materials and ptomains contained in flesh foods. Such patients, in times of crises, frequently emit pronounced odors of raw meat or uric acid. Strictly vegetarian diet, combined with other eliminative natural methods of treatment, cures the majority of these cases.

Most of these poisonous acids, alkaloids and ptomains contained in the flesh of dead animals are powerful stimulants. I have frequently noticed that people who have abstained from meat for a long time, when they first partake of it again experience sensations and exhibit symptoms resembling those of alcoholic intoxication.

We have learned that these stimulating extractives of flesh foods chemically closely resemble caffeine, thein and nicotine. The use of one or more of these stimulants invariably creates a craving for the others. This explains why a heavy meat eater is usually a confirmed coffee drinker or inveterate smoker, and vice versa; and why we find it almost impossible to wean people from one of these stimulants as long as they persist in taking the others.

The legumes or pulses—peas, beans and lentils—are close seconds to meat in acid-producing qualities. Eggs contain considerable ready-made uric acid and a great deal of sulfur and phosphorus. These may become dangerous to the organism. For these reasons, meats, legumes and eggs are always danger foods for the child.

Children brought up on such foods will show the effects in nervousness, irritability, lack of self-control, craving for cigarettes and alcoholic stimulants. The most serious aspect of this question lies in the stimulative influence of meat poisons.
on the sex centers. It is a well known fact, verified by close observation, that flesh foods stimulate the sexual passions to a marked degree. This tendency is greatly increased by the use of coffee, tea and alcoholic stimulants in the form of wines, liquors or medicines. If the sensitive nervous organism of a child is overwrought by these powerful irritants, there can be but one result; precocious sexual awakening.

From the third year the child may gradually adopt with slight appropriate modifications, a diet as outlined under Sec. I, No. 10, and Sec. X, No.7.

SECTION XL

Exercises in Infancy

1. Exercises in Infancy. Proper exercise is important from the very beginning of life. A baby will follow its natural instincts for exercise if allowed to do so, by working its arms and legs and writhing its little body in all directions, if not unduly hampered by tight clothing and bandages. A few nude air baths every day will afford excellent opportunity for baby's gymnastic stunts.

After he is a few months old he may be placed on his stomach, when he will exert himself vigorously by trying to raise his head, to turn around, or to raise himself with his arms. He will soon learn to roll over and to creep lie nay now be pulled up gently by his arms and lowered again a number of times in succession.

When three or four months old he may be lifted by one arm or by both arms; by the right arm and left leg, or by the left arm and right leg. When the baby is six or eight months old, he should be strong enough to rise from his back to a sitting position. This may be encouraged by holding down the feet. I have known a number of nature cure babies who at six months of age clung tightly to a stick while being lifted a few feet from the bed. Another good exercise greatly enjoyed by the youngsters is to roll them back and forth on a bed.

The average healthy child will secure ample exercise while learning to walk and run and while playing with simple toys or with other children; but this may be supplemented to good advantage by special exercises devised by the father and mother. Nothing is better for the health and happiness of both parents and children than to join in merry romp and play.

Between two and five years of age the child may be taught more difficult stunts, performed either by himself or with the assistance of the father or mother; but swinging the child high overhead, throwing him up and catching and other dangerous tricks should be avoided. They are risky and have very little effect in developing the body of the child. The best exercise at this age consists in outdoor play and games.
From the sixth year, the question of exercise becomes a more important one, especially since the children are confined for many hours in school rooms. If exercise at this time of life, through play and games and special gymnastics, is neglected, it may affect health, strength and efficiency of the child for life.

Those of good physique and ample strength may gradually take up and practice the exercises for adults outlined in sections XXI, XXII, XXIII, XXIV.

2. High Chair. A baby should not be put in a high chair until he is quite well able to hold the spine and head erect, and should never be left in a chair for any length of time. If a baby is forced to maintain a rigid, sitting position for a considerable time, before the bones and muscles are sufficiently developed, this may produce deformity of the spine. Maids and nurses, if not properly supervised, sometimes fasten a baby in a high chair and leave him there to take care of himself for long periods.

3. Toys. Since most babies have a habit of putting everything into their mouths, toys must be selected that can do no harm. They should have no paint, no sharp points or corners which might hurt the eyes or mouth, and must be of material which can be easily and thoroughly cleansed. Hairy and woolly playthings are unsafe, being unclean and germ carriers. Objects small enough to be swallowed must never be put within baby's reach. The simpler the playthings the better; a few clothespins, empty spools, or other simple objects are better than expensive toys.

SECTION XLI

Baby's Ailments

1. Hernia As a result of a weakly or sickly condition of the mother during pregnancy and of faulty prenatal management, many children are born ruptured. So far I have not known a single nature cure baby that was born ruptured. Such defects are due to weakness of the tissues. This results from mineral starvation. The tissue walls contain too much mortar (protein) and not enough building stone (mineral salts). Prevention of hernia, therefore, lies mainly in proper diet of the pregnant mother, but all the rest of the prenatal regimen described in these pages is of great importance in preventing this and other ailments and deformities.

There are three principal points at which rupture or hernia may take place in infancy—at the navel, in the groin, and at the line between the navel and the lower end of the sternum. Other kinds of ruptures are extremely rare.
2. **Umbilical Hernia**

This is a protrusion of the intestine at the navel. It is the most common rupture in infancy. Pulling on the cord during childbirth, urging at stool or violent crying may result in rupture. The umbilical ring first expands and this forms a pouch into which one of the folds of the small intestine protrudes.

Treatment: Of primary importance is the diet as outlined herein. The baby must have plenty of fruit juices in order to reinforce the mineral salts in the milk. Cold bathing is very beneficial. The rupture itself should be cleansed several times a day with warm water. This must be followed by a wash with cold water mixed with lemon juice. Gentle, passive exercise, such as raising, lowering and twisting the limbs from side to side, also raising and lowering the body while supporting the shoulders and head, is of especial value.

The rupture must be reduced and kept from protruding by placing over it a large button or other article of similar shape, wrapped in gauze and held in place by broad strips of adhesive plaster. The adhesive tape is fastened over the button crosswise and must be applied in such a manner as to draw the skin from all sides over the rupture. Instead of the button, a compress made of gauze may be laid over the rupture and held in place by one broad adhesive strip. The covering of the rupture must be removed and renewed every day in order to allow cleansing, as before described.

When the child is old enough to exercise by himself, he should be taught special movements of the body and the limbs which develop the muscles of the abdominal region.

3. **Ventral Hernia.** This occurs along the middle line of the body between the navel and the breastbone, sometimes below the navel. The rupture may not be larger than the size of a pea or small marble, and may disappear on pressure. The treatment is the same as that of umbilical hernia.

4. **Inguinal and Scrotal Hernia** occur in infancy or in adult life; sometimes the inguinal canal does not close after the descent of the testes from the abdominal cavity into the scrotum, and the intestine descends through the open canal, thus producing the rupture. These forms of hernia become aggravated by coughing. They can be reduced immediately with gentle manipulation while the patient is lying on his back. This kind of rupture may be distinguished from hydrocele by the fact that in reducing it goes back easily with a gurgling sound. Hydrocele is not affected by coughing. A hernia is opaque to transmitted light; hydrocele, transparent.

These ruptures should be protected with a well-fitting truss. This has to be removed daily for cleansing of the parts. Appropriate exercises, passive and active, together with cooling sitz baths and washes with cold water and lemon juice are the best remedies for these, as well as of other forms of rupture.
5. **Congenital Hernia** occurs in the form of inguinal hernia and has to be treated in the same way. Ruptures of any kind must be reduced and properly supported. Constipation and consequent urging at stool may cause or aggravate any form of hernia and must, therefore, be overcome by the right treatment described under section XXVI, No.1.

6. **Colic.** This is usually caused by indigestion due to overfeeding, improper feeding, or too frequent feeding. The intestines are distended with gas, giving rise to a severe pain. The baby cries sharply, alternately drawing its legs up to the body and kicking them away. One of the quickest means of relief is a small enema of warm water and gentle circular massage of the abdomen from right to left. Food should be withheld until the symptoms have disappeared. The giving of milk or other food may quiet the attack temporarily, but the pain is apt to return with greater intensity. Warm water may be given if the baby will swallow it.

A baby managed in the natural way prenatally and postnatally is not likely to suffer from this ailment. Constipated babies are more prone to it than others.

Colic may also be caused by sudden chilling. In that case a warm bath for five or ten minutes, followed by gentle body massage will bring about a warm reaction.

7. **Convulsions.** These cause a great deal of anxiety to the fond mother. They are always reflex symptoms of some slight or serious internal disturbance due to wrong management. They commonly result from some form of auto-intoxication caused by digestive disturbances, and the resulting systemic or drug poisoning. An inactive condition of the skin, bowels or kidneys will favor auto-intoxication and convulsions. If proper care is taken to keep the system pure, and the organs of elimination in active condition, convulsions will not occur.

The best treatment during an attack is a quick, cold rub all over the body; application of a whole body or trunk pack; gentle soothing magnetic massage, and neurotherapy treatment. These treatments draw the blood into the surface and relieve congestion in the brain and nervous system.

8. **Ailments of Teething.** Many ailments of children are laid to teething, but this is a mistake. Well managed, healthy babies go through the teething period without any trouble whatsoever. This is practically always true of nature cure babies. When, however, the little body is heavily encumbered with hereditary and acquired morbid materials, food poisons and disease taints, the process of teething will not run its natural course and may precipitate any form of disease crisis.

When teething is difficult, it is frequently associated with digestive disturbances. Diarrhea may alternate with constipation and vomiting is of common occurrence. The baby may be restless and fretful. He tries continually to bite on something in order to facilitate the projection of the teeth
through the hardened gums.

No teething lotions or soothing medicines of any kind should be given for the relief of pain in teething. They all contain poisonous sedatives which benumb and paralyze the nerves and have serious after effects upon the system. They usually contain opium in some form, or other narcotic drugs.

The only way to prevent these and other infantile ailments is to keep the little body as nearly normal as possible through the natural treatment described in these pages. If this is closely adhered to, it will prevent, in many cases, the development of even measles and other common eliminative infantile ailments.

During this critical period in the baby's life the diet must be extra light; starchy food should be reduced to a minimum and replaced by raw and cooked fruits and vegetables juices. Cooling sitz baths will help to keep the bowels active and to abate internal fever.

**9. Acute Catarrhal Disease.** Acute catarrhal diseases of infancy such as croup, cold in the head, acute bronchitis and whooping cough, are different forms of acute elimination through which Nature tries to purify the little body from hereditary and acquired accumulations of morbid matter, systemic poisons and disease taints.

In accordance with this conception of acute diseases, as purifying, healing efforts of Nature, we would not do anything to check or suppress elimination but cooperate with Nature in her purifying, healing efforts. How we do this has been fully explained in other parts of this volume. (Section VIII)

The natural treatment is very much the same in all acute inflammatory ailments. Feeding must be reduced to a minimum. If the baby does not insist upon eating, nothing should be given except water with acid or sub-acid fruit juices, such as lime, lemon, grape fruit and orange. If the temperature does not run high, say not above 100 or 102 deg, frequent ablutions with cold water at intervals of from one to two hours will be sufficient to promote heat radiation and elimination of morbid matter through the skin and other organs of elimination. If the temperature runs' higher, say between 102 and 105 deg, wet packs must be applied, and renewed when they become hot or dry.

The wet packs are of especial value in all kinds of cough; whether it be the ordinary cough, croupy cough or whooping cough. A whole body or trunk pack, with or without a throat pack, will give almost instant relief. In many instances where baby is making the night hideous for the anxious mother, with it's coughing, a well-applied whole body pack, or a combination trunk and throat pack, will relieve the coughing almost instantly, and induce restful sleep.
In serious cases it is always advisable to call in a natural therapist or some other drugless physician, if one can be reached.

The mother should not forget that all acute diseases, after they have once developed, must run their natural course. She must, therefore, not become impatient and lose faith in the natural treatment if it takes a week or more to cure a common cold in the head or an attack of bronchitis, or if it takes from two to eight weeks to cure a case of whooping cough. Serenity, patience and cheerfulness are the primary requisites of the nature cure physician.

PART IV

BABY BOOK

Natural Therapeutics has undoubtedly solved the problem of treating human ailments. All other schools and systems will in time have to adopt the natural way. It is the hub of the healing art; all therapeutic methods radiate from it like spokes from a wheel.

Natural Therapeutics, however, has something better to give than treatment of disease, and that is prevention of disease. If children were brought into this world in the manner ordained by Nature and reared in harmony with the teachings of natural philosophy, disease would soon be a thing of the past. Human beings would then enjoy good health and be as beautiful and perfect in their kind as are animals, which live in the freedom of Nature, guided by instinct and therefore in harmony with the laws of their being.

We must begin, then, with prevention, for prevention is always easier and cheaper, than cure. But where must we begin to study the prevention of disease? Some will say, "At birth, because that is the beginning of life." Not so: that would be too late. The mould is made and the foundation laid for health or disease, for happiness or suffering, for efficiency or deficiency, before the human being in process of creation sees the light of day.

"Then," it may be said, "we must begin with prenatal influence, for the physical, mental, emotional and moral habits of the mother influence powerfully the development of the new life she is carrying." True—but we must start earlier than that. The making of the human being begins with mating and conception. All subsequent development depends upon the right start.

SECTION XXXII

Heredity

1. Importance of Correct Mating. Of primary importance in the sacred rite of procreation, as already intimated, is mating. This should take place only between descendants of the same subrace, or of closely related subraces such as the Indo-Caucasian and Celtic.

If the racial descent of the marriage partners is so far removed that it has produced pronounced differences in racial
characteristic—as in the case of the swarthy Mexican and white skinned Englishwoman, or the dark eyed Magyar and blue-eyed Scandinavian—then procreation becomes miscegenation and degenerates into mongrelization of the offspring. Everywhere in the animal and human kingdoms Nature has set the mark of disapproval on the mongrel. The offspring of miscegenation is doomed to deterioration and extinction unless assimilation of the elements of a lower race by a higher takes place sparingly and gradually.

The law of racial purity may be summed up as follows: When a member of a higher race cohabits with a descendant of a lower race, the offspring of the union loses more or less the characteristics of the higher race and reverts in physical, mental and moral traits to the level of the lower race.

The constructive results of racial purity are evident in Hindus of the higher castes; in that portion of the Jewish race which in mating has faithfully adhered to the Law of Moses, and in the blond and blue-eyed remnants of the Indo-Caucasian and Celtic races in Northern Europe and North America. The destructive results of miscegenation are plainly evident in the mongrelized population of Mexico and everywhere in the half-breed and many kinds of mixed breeds. These usually fall below the physical, mental and moral standards of the parent stock, and almost invariably revert to the customs and habits of the inferior race.

2. Use Heredity. Use heredity deals with the transmission to offspring of acquired physical, mental and moral characteristics of the parents. According to this law as it has been formulated, the chances of the offspring for long life, health, mental efficiency and moral stamina, other conditions being favorable, are better in direct ratio to the advancing age of the parents at the time of conception. While this is contrary to popular opinion, which assumes that younger parents produce more perfect offspring than older ones, the fact of use heredity is proved, both in the animal and human kingdom, by common observation and statistical evidence.

The working of the law is based on the fact that the procreative elements of the parents, or rather the microzyma of those elements, cannot contain the impress of physical, mental and psychical characteristics which at the time of procreation were not developed in the threefold organisms of father and mother.

The age of the father at conception is called the "birth age" of the offspring and determines its birth rank. While the father and previous male ancestors, for reasons hereafter explained, seem to exert greater control over the mental and physical characteristics, the mother furnishes the nutrient soil for physical growth. This does not mean that she exerts no control over the mental and psychical characteristics of the offspring; in addition to her influence through use heredity she has added opportunities through prenatal influence and postnatal training.
According to this law, then, the chances of the offspring for excellent physical, mental and moral development become better as the age of the father at the time of procreation advances beyond thirty five; while the physical condition of the mother for reproductive function is best below thirty five years.

But we must not overlook the fact that too great a discrepancy of age between the man and woman may become the cause of physical and mental incompatibility, of aversion and great unhappiness, especially on the part of the younger woman.

Extensive statistical evidence seems to prove that the birth age of the mother has been of less importance than that of the father. As will be shown in Natural Eugenics, the majority of famous men in all lines or human endeavor had old male ancestors, while the mothers and previous female ancestors were of much younger age at the time of conception.

This may be accounted for by the following reasons:

The man is usually considerably older than the woman at the time of marriage. Men, as a rule, devote much more time and effort to acquiring a scientific, professional or business education than do women. This has been true in the past more than it will be in the future. Thrown early into the competitive struggle of life men generally have had to make greater mental and physical effort than have women.

These points are of considerable importance because it has been proved that it is not inherited brain mass and mental capacity, but strenuous and persistent effort that intensifies use heredity. The earlier this begins and the longer it continues before procreation takes place, the better the chances of the offspring for physical, mental and moral capacity.

The reproductivity of the mother has usually ceased at thirty-five. Though she be capable of childbearing a few years longer, usually conception has been avoided after that age. Men under favorable conditions remain reproductive to advanced age. Some of the world's greatest men descended from fathers over sixty years old.

That intellectual and creative capacity has followed the male line of descent rather than the female line, is indicated by the fact that the high intellectual capacity of many eminent men has skipped their daughters to reappear in male descendants. This may be partly accounted for by the fact that the daughters in their limited spheres of activity have not had the opportunity to unfold inherent intellectual capacity to any conspicuous degree.

There has been a tendency in some quarters to criticize the general entrance of women into professional and commercial life and to dilate upon the adverse influence this will have
upon womanly characteristics and family life.

In the light of the knowledge we possess upon the subject of use heredity, it is safe to say that any such problematical drawbacks will be far outweighed by the general postponement of the marriage age. This will insure not only better physical fitness but also higher intellectual development and greater moral stamina on both sides of parentage.

The tremendous benefits which this increased hereditary endowment will confer upon future generations cannot be overestimated. Greater intellectual and economic equality between the sexes will emancipate woman from degrading sexual subservience. Under the old order, sex appeal was too often her only stock in trade by which to attract and hold the male and thus to secure a living. Economic independence will insure greater consideration and higher esteem for the woman on the part of the man. It will go a long ways toward solving the problem of birth control in a natural way, by leaving it more largely to the judgment of the mother.

We find the law of use heredity according to birth age verified in the intelligence and moral development or obliquity of races, nations and tribes all over the earth—The lower the average birth age of a race or nation, the lower, other things being equal, the intellectual and moral development The greatest development and efficiency is found among those nations where marriage is delayed to a later age through custom, economic necessity, professional or military training.

The following quotation from "Control of Heredity", by Casper Lavater Redfield, is of interest in this connection:

"In general it may be said that wherever there are no restraints upon the sexual propensities, as with the Digger Indians, the Fuegians, the Andamanese, the Wauraus of the Guianas, the Bushmen and the tribes along the Gabbon river, there we find reproduction taking place at the earliest possible age, and the lowest grade of intelligence. Where we find some special circumstances or customs that delay the age at which reproduction takes place, as with the Patagonians, the North American Indian and the Polynesians, there we find considerably higher grade of intelligence.

"Where we find the custom of marrying late in life, as was customary with the Greeks and the Romans, there we find a very high grade of intelligence. And where we find a fortuitous succession of very late births, there we find the very great men of the world's history.

"In other words, the longer the time in which the individuals have in which to use, develop and strengthen their brains before reproduction begins, the greater and more powerful are the brains of their descendants."

In Volume IV of this Series I shall quote elaborate and
highly interesting statistics from Redfield, which reveal the effects of the various birth ages on physical, mental and moral characteristics. I shall confine myself, for the present, to the statement that, with few exceptions, the great artists, scientists, philosophers, statesmen and philanthropists were born from fathers whose ages ranged from forty to sixty-five years at the time of the procreation of their famous offspring.

The existence of these laws and principles as facts in nature is very evident in the training of racehorses and of other animals along certain lines of proficiency.

3. Pernicious Heredity. The effects of deteriorating and destructive heredity prenatal and congenital influences have been traced and commented upon in so many different ways that I do not believe it necessary to enter deeply into this phase of the subject. Various authors have filled entire volumes with the unsavory family histories of the descendants of the Jutes, Ishmaels and other drunkards, prostitutes, degenerates and criminals, which prove positively the transmission of morbid and pernicious traits through successive generations. It has been proved statistically beyond the shadow of a doubt that youthful delinquency, pauperism and criminality are the aftermath of immature marriages.

The laws of use heredity and prenatal influence, like all other natural laws and principles, manifest along opposite lines of expression. It remains for us to determine whether we shall align ourselves with their destructive or constructive activities. The effects upon ourselves and our offspring will show accordingly.

If I succeed in arousing the consciousness of prospective fathers and mothers to the glorious privileges and enormous responsibilities which these laws of nature confer upon them, then my labor will not have been in vain and I shall feel deeply gratified.

SECTION XXXIII

1. The Creative Alchemy of Love and Affection

Procreation—as is the case with everything else pertaining to the constituents and functions of the human entity—takes place on three planes of being, the material (physical and spiritual), the mental and the psychical planes. Which of these elements shall predominate in the offspring depends upon the mixture and adjustment of qualities in the triune makeup of the mating couple. In order to fulfill the law and to draw the divine blessing upon themselves and the fruit of their union the partners in the procreative function must be united by the bonds of love, or at least by the ties of true affection.
The source of creative genius is love and wisdom, and the essence of intelligence and power is sincerity and goodness. Without these, intelligence degenerates into selfish cunning, power into self-destructive brute force. The spring cannot rise higher than its source; its water cannot be pure and wholesome when contaminated by impure admixtures from filthy surroundings.

It is not generally known that use heredity pertains to intellectual and psychical qualities, as well as to the physical material. Animalism breeds nothing but selfish animalism. The vampire who craves and absorbs the love of its victims and robs them of vital energy, without being capable of feeling or bestowing affection, is the child of a discordant union—of brute animalism on the part of the man, of secret aversion and hatred, usually, on the part of the woman. These bestial and degrading tendencies on the one side, and unrequited love craving on the other, breed sex perversion, and propagate the harpies who delight in the seductive power of superficial beauty, while gloating over the weakness and ruin of their victims.

True love and affection, paired with intelligence and goodness; liberate the creative elements necessary to the production of perfect offspring.

The finer qualities of mind and soul open the fountains of life on the higher planes, liberate and harmonize the male and female procreative fluids, and charge them with the purest and most potent intellectual, spiritual and psychical elements.

The divine fire of creative genius burns only in the love aura of truly mated couples. It is true that these are rare under our artificial, unrighteous social institutions, and that accounts for the rarity of complete manhood and womanhood.

Perfect offspring, endowed with beauty and power of body, mind and soul, destined to shed through life a radiance of health, happiness and helpfulness—to love and be loved—issues only from the union of love and affection with intelligence and goodness.

"Love lieth at the foundation" (of all that is). "Love is passion, enthusiasm, affection, heat, fire, soul—God."

To the extent that love enters into the holy rite, to that extent its attributes will be absorbed in the threefold organism of the woman and become active in the child building in her womb. While she loves her man more than ever, her most passionate affection is centered in the new being in process of development. On it she bestows the purest and best in her food and drink, in her thoughts, emotions and secret desires. Fear, worry, anxiety, jealousy and hatred are strangers to her soul; these are the emanations of the lower spheres—she lives in heaven.

Somebody endowed with deep insight into these matters has
said:

"Whatever male and female shall truly will for, hopefully pray for and earnestly yearn for, when love pure and holy is the nuptive ascendant, in form, passioned, affectional, divine and volitional, that prayer shall be granted, and the boon be given—but the prayer must precede."

What are the direct effects of the marital rite upon the participants? If the sex attraction operates on the physical material plane only, if lust instead of love presides at the matrimonial feast, then temporary gratification of erotic craving will be followed inevitably by monotony, satiety, gradual revulsion and aversion, culminating in a morbid craving for change and variety. The partners in carnal self-indulgence are intuitively aware of these tendencies to marital unfaithfulness, and, therefore, easily dominated by distrust and jealousy.

The procreative function is attended by complete satisfaction, buoyancy of body and mind and lasting happiness only when sex attraction operates on the higher and highest planes of being, as well as on the lower, when desire and impulse are operative on both sides. Thus only will the generative function fulfill its sacred purpose and confer the highest possible benefits upon parents and offspring.

The woman, being the more highly sensitized, must be responsive to the call of holy passion. To force unwilling compliance will ruin the woman, kill her love and curse her offspring. Balzac says: "He who begins with his wife by a rape is a lost man." It is impossible for a wife to love unless she is won, not forced to compliance.

2. Sexual Intercourse During Pregnancy. Sexual intercourse should be considered the most sacred function of the human entity. From the highest and best viewpoint it should be exercised only for the propagation of offspring. However, considering the present stage of ethical and moral development, temperate indulgence may not be wholly condemned. Excessive intercourse is always weakening and harmful to both participants. We must remember that the sex fluid is the carrier of the life force. It is that which constitutes strength, resistance to disease, initiative and genius. During abstinence from intercourse the sex fluids with their creative energy are absorbed through the inguinal glands into the organism and increase physical, mental, moral and spiritual capacity and energy.

Set rules for frequency of intercourse cannot be given. This must depend entirely upon individual conditions. One safe rule is that after indulgence there should be no feeling of satiety, weakness and exhaustion. The more frequent the indulgence the stronger will grow the power of habit and of passion and the greater will become the abnormal craving. It is the same with all other appetite and passions. The more frequently they are indulged, the stronger they grow, until
they attain complete control and develop into destructive habit

A free and confidential understanding in regard to these matters between those who contemplate matrimony would go far to prevent marital misery. A great deal of unhappiness arises from the fact that mates in the matrimonial union often labor under misapprehensions concerning the attitude of each toward the sex relation, and are prevented by excessive sensitiveness and delicacy from frankly discussing it. (For further discussion of this subject, see page 390, Volume I.)

There is no problem of married life that needs more thorough mutual consideration and understanding than this one. Lack of it accounts for a great deal of "incompatibility," loss of love, revulsion, hatred, and the final tragedy in the divorce court.

Among animals, no female allows intercourse after conception. In this respect as in many others, man has sunk below the natural standards of the animals. No greater crime can be committed against the woman and the unborn life.

It is a sad commentary on our system of education, scholastic as well as religious, that our young people are not instructed before and after marriage in these all important laws of Nature. To do this should be the province of the priest who unites them in marriage, or of the family physician, if the parents have failed in their duty.

It is well known (notwithstanding the denials of medical skeptics) that the unborn infant may be "marked" by transitory impressions, especially by strong emotions; that even insignificant parental characteristics are reproduced in the offspring. Is it any wonder, then, that the most powerful of human emotions should leave its impress on the growing brain and sex centers of the fetus, causing abnormal and precocious sex consciousness?

All too often is sex perversion born and bred in bone and flesh, before the child sees the light of day. The mother cannot be blamed for this "slaughter of the innocents"; she has not been instructed on the subject. Though she intuitively senses the horror of it, she submits, in order to maintain her hold upon the man—and many a life is thus cursed before it is born. The fault lies primarily with those of the medical profession who teach our young men that the free indulgence of sexual passion is not only legitimate, but a necessity to manly vigor.

This dictum of pseudo-science is almost universally concurred in by spiritual guardians. No greater lie was ever promulgated from the blackest abyss of Hades. If our young men were taught that greater happiness is to be attained by the exchange of tender affection than by the indulgence of the coarser animal appetites, that the creative forces thus preserved develop and strengthen their own finest capacities
of body, mind or soul, they would wisely and chivalrously protect mother and child, at the same time conserving their own physical and moral integrity.

In no other way is it possible to call forth the deepest gratitude and unfailing esteem of a true woman. Many a man whom we have thus advised has become a lifelong friend in consequence.

3. Limitation of Offspring. I believe that the unlimited production of offspring, encouraged in some quarters for swelling the ranks of religious bodies or for increasing tax paying and cannon-fodder material, is a misfortune, both to the family and to society. Limitation of offspring, in accordance with the means and circumstances of the parents, is not only justified but should be encouraged. In any case, the production of offspring entails great responsibility upon the parents and if they cannot properly comply with the needs and rights of their children, they fail in their responsibility and duty.

Any method, however, which interrupts intercourse or prevents conception in an artificial way, is absolutely to be condemned, because this has very harmful and positively destructive effects upon the physical, nervous and mental organism of those who thus try to cheat nature by the suppression of a natural process. In our professional work we frequently meet the victims of such pernicious practices. The ordinary contrivances for prevention make of intercourse something akin to masturbation. This is also true of intercourse without orgasm which is strongly advocated under various guises. The use of poisonous antiseptics and germ killers in warm water douches is not essential for prevention, and is highly injurious. These chemicals have a tendency to poison the sexual organs and to produce in time atrophy, many kinds of female disorders, and tumors. Undoubtedly the greater number of so called female troubles and malignant tumors in later life are caused by curetments, antiseptic douches and the use of poisonous drugs, for producing abortion. The only legitimate methods of birth control are abstinence or common cleanliness.

There is nothing more conducive to the physical, mental and spiritual health and development of a woman than childbearing and child rearing in harmony with Nature's laws, as outlined in these volumes. Under favorable conditions it is not a thing to be dreaded, but to be looked upon as the greatest of blessings and opportunities in the life of a woman. Natural philosophy and practice takes these problems of progeneration, childbearing and childrearing out of the domain of uncertainty and haphazard management with its dire consequences, and makes eugenics the most exact of all sciences and the sublimest and most enjoyable of all the arts.

4. Determination of Sex. Numerous theories have been advanced concerning this interesting subject. Many attempts have been made to wrest from Nature the secret of sex
determination and numerous more or less ingenious methods have been recommended for sex control.

I know of one method only which seems to have a rational basis and which has proved of practical value. Observations seem to prove that the right ovary liberates male ova only, while the left ovary discharges female ova. The two ovaries discharge ova only at alternate menstruations.

With this data at hand, it is possible to determine the sex of a child after one birth has taken place. Suppose the first child was a boy. By consulting our pregnancy table (page 377) we can determine when the last menstrual discharge took place. This menstruation liberated a male ovum; the next menstruation would liberate a female ovum, the next a male, etc.

Thus, using the last menstruation period before the last conception as a fixed point, it would be possible, figuring from period to period, to determine the sex nature of the ovum to be discharged at each following menstrual period. Account is taken of all regular periods during the time menstruation is suspended in pregnancy. Thus, conception may be timed in such a way as to impregnate at will a male or female ovum.

This solves in a simple, rational manner another of Nature's riddles, namely, the reason for the practically equal division of the sexes.

SECTION XXXIV

Prenatal Influence

There exists just as much diversity of opinion among scientists concerning the reality of prenatal influence as about race heredity, use heredity, disease heredity and many other mooted problems of science and philosophy, which we shall study in Vol. IV of this series. In the following I shall present and examine impartially the various theories and opinions concerning prenatal influence; then we shall be better prepared to draw our own conclusions.

1. Medical Science Denies Prenatal Influence. Medical men, as usual cocksure of the correctness of their theories and hypotheses based on the "latest discoveries", deny and ridicule the possibility of prenatal influence, and relegate it to the rubbish heap of popular superstitions. They base their judgment on the fact that no nerves pass from the body of the mother through the umbilical cord into the growing fetus in the placenta, which forms the soft protecting nest of the new life within the womb. They claim that since no direct nerve connection exists between the two, mental and emotional vibrations cannot be transmitted from the brain of the mother to the brain and nervous organism of the fetus.
Are there no other means of communication between the mind of the mother and the brain of the unborn!

In the volume dealing with Eugenics we shall learn how universal intelligence and creative will become individual intelligence and personal will.

Cosmic vibrations do not flow into the gray matter of the human brain over coarse physical nerve tracts. They come over the psychical wireless which connects the human soul with the world Soul, the individual intelligence with the universal or cosmic intelligence the human will with the divine will.

Since, as proved by modern brain and nerve anatomy, immaterial cosmic intelligence and "power to will" fashion the brain of the mother into physical material centers for the expression of human intellectual faculties, capacities and powers, why cannot these cosmic vibrations act in like manner over the psychic wireless through the soul and mind of the mother on the brain and nervous system of the fetal organism?*

These epoch making discoveries and revelations of modern brain anatomy are explained in Vol. IV of this Series, *Natural Eugenics—Man Building on the Physical, Mental and Moral Planes.*

Why should the wireless, which transmits impulses of intuitive intelligence from the great source of all intelligence and creative energy into the soul of the mother, cease to operate at that point, and fail to transmit its message to the brain and nervous system of the fetus which is most intimately related and connected with the organism of the mother?

What about the phenomena of hypnotism? Absolute control of the subject's mind, through the intelligence and will of the hypnotist does not depend upon the existence of an umbilical cord and physical nerve connection between the two. The hypnotist, by silent command, may call his subject from a distance, far beyond the reach of his voice.

People telepathically attuned may communicate in like manner, spontaneously, or by conscious intent. Why then should we doubt the possibility of vibratory correspondence between the mental and emotional conditions of the mother and the plastic nervous organism in process of development within her womb?

If a complexity of sound can impress itself permanently upon the wax cylinder of a phonograph, or what is still more marvelous, if the photographic rays of passing scenes can be fixed and retained in the picture film, why should it be impossible for the mental and emotional vibrations of the mother to impress and modulate the molecular and cellular constituents of the fetal brain and nervous organism?
I have compared this creative power of the mother mind to
the process of electrotyping. As the particles of metal in
suspension in the fluid adhere to the spoon that is to be coated
with silver, so the atoms and molecules in the gray matter of
the brain of the fetus group themselves in harmony with the
thought forms and emotional vibrations of the mind and soul
of the mother. While this mental and psychical electrotyping
takes place automatically, the mother’s brain and nerve
molding power can be greatly strengthened and intensified by
the conscious and voluntary operation of the psychical
wireless that establishes vibratory oneness between her and
the human entity in process of development within her own
body.

Thus it is revealed how a brain prenatally refined, organized
and fashioned may endow the nascent individuality with
certain aptitudes and talents along established paths of
cerebration. There surely will be less resistance along such
lines of physical, mental and moral endeavor than along other
lines not prenatally influenced and molded. Therefore I
strongly advise mothers, pregnant with new life holding
marvelous possibilities for good or evil, not to be influenced
by the superficial reasoning of materialistic science, but to
follow the sacred intuition and impulse of their own creative
genius in this, the most holy function of their being. Every
normally constituted mother is intuitively aware of this
wonderful power, and is willing and anxious to exercise it
when her consciousness has been aroused to the great
possibilities and responsibilities which the divine privilege of
motherhood confers upon her.

It is natural for us to admire a great artist who portrays the
human form, true to life, on the painted canvas, or who
fashions it from inanimate stone, metal or marble; how much
more grand and godlike is the creative power of truly mated
parents whose privilege it is to bring into the world, and to
fashion according to their highest ideals, a human being
endowed with life and intelligence, with the infinite
possibilities of a new center of creative activity.

Yet many mothers, totally ignorant of their divine creative
privileges and possibilities, victims of physically and morally
degrading marriage relations, and often filled with secret
aversion or open hatred for their marital companions, pass
unwillingly through pregnancy and not infrequently seek to
destroy the new life. When the unfortunate victim of such
marital incompatibility, conceived in passion and developing
under the worst possible influences of mental and emotional
discord, comes to arouse the maternal instincts of affection
and devotion, then fear, anxiety and worry, like a continual
nightmare, haunt the unhappy mind of the mother and impress
their discordant vibrations upon the sensitive films of infant
consciousness.

Compare this condition of fear, apprehension and gloom in
the mind and soul of an unhappy and unwilling mother, with
the joyful and ecstatic state of mind of a mother conscious of
the creative power of her intelligent will, who, from the time of mating and procreation, with accurate prescience prepares the most favorable conditions, astrologically, prenatally and postnatally for the finest development of the physical, mental and moral characteristics of the future world citizen.

The loftiest exaltation of a creative genius working in dead clay and cold marble cannot approach the ecstasy of a mother who has acquired a knowledge of the great laws which make possible the development of a perfect human being, the embryo of a master, an angel, a being destined to be godlike in its faculties, capacities and powers!

In place of fear and anguish of soul, what joy to the mother who knows that it lies within her power to prevent disease and degeneracy in her offspring; that the development of the child depends solely upon her own intelligent effort! Nothing is left to accident. Child bearing becomes an exact science, the most beautiful and inspiring of all arts and professions. Under such conditions motherhood, instead of being the greatest of hazards and hardships, becomes a divine privilege and the highest achievement of human existence and endeavor. It falls short only of the creative work of the great Universal Intelligence whose instrument of creation is the mother.

2. An Example from History. Let us consider the oft-quoted example of Napoleon Bonaparte. His mother, Lutitia Bonaparte, while pregnant with the future military genius, accompanied her husband on a military expedition, sharing with him the hardships and excitement of camp life, and the marches and battles of a military campaign. If there be nothing in prenatal influence, is it not singular that Napoleon should have become one of the greatest military geniuses of all ages, while not one of his many brothers ever exhibited enough military ability to make an efficient corporal? What was it that favored or determined the birth of the great military prodigy under these circumstances? The ancestors of Napoleon's father were not professional soldiers, nor was the father especially interested in military matters before the conception of his gifted offspring.

The dominant influences, therefore, must have operated through the singular occupation and surroundings of the mother during this particular pregnancy.

Many similar striking examples have been cited in works on prenatal influence. I myself might add many convincing proofs from an extensive experience in medical practice; but time and space do not permit. Contributory evidence may be secured from many excellent works dealing with this vital problem in human life. I may be permitted to say that use heredity and prenatal influence are distinctly manifest in the physical and mental characteristics of our three children who were born at intervals of seven and five years. Each one of them clearly mirrors in his or her physical, mental and emotional peculiarities the predominant mental tendencies, occupation and surroundings of the parents during the
respective prenatal periods. Similar manifestations of prenatal influence may be observed in almost any family.

3. Birthmarks. Medical men of late deny also the possibility of "marking" the offspring by sudden fear or shock on the part of the mother during pregnancy. Incidents of this kind, however, are of such common occurrence that it is a waste of time to refute these flippant denials.

There are good reasons for believing that such marking is more likely to occur during the periods when the menstrual flow should take place, but is suspended.

It may be argued that to mention the possibility of marking to a pregnant woman will greatly increase the probability of electrotyping violent emotions upon her offspring; in other words, that the fear of the thing will help to materialize it. This may be true to a certain extent, but we must remember that sudden shock through fear or disgust may cause the mischief anyway, whether or not the expectant mother is aware of the possibility. Understanding a danger and being prepared for it seems the best protection. The pregnant woman should study carefully section XXX, dealing with mental and emotional causes of nervous diseases, and should learn to relax to any sudden surprise and thus neutralize unpleasant and fear arousing impressions. Self-control is the royal remedy and the key to mastership.

4. Physical Influence. Now that we have studied some of the more important hereditary mental and psychical prenatal and postnatal influences, let us see how the physical condition of the mother's organism influences the brain and nerve matter of the fetus in its last stages of development, and after birth.

Materialistic science teaches that brain matter exudes thoughts and feelings, as the liver excretes bile, or the stomach peptic. Natural science proves that mind is superior to matter, that the new born ego, by the power of intelligent volition, must fashion in the gray matter of the brain the molecular groupings or centers for the expression of intellectual and emotional activities, such as language, music, numbers, scientific and philosophic speculation.

This means that active cerebration and brain molding do not begin until after birth. But it stands to reason that the work of the nascent intelligence may be greatly facilitated or impeded by the physical condition of the brain. It is reasonable to assume that intellectual and emotional vibrations will more easily shape the gray matter of the brain into new configurations when it has been prenatally refined, organized and developed along certain lines of cerebration by use heredity and by constructive prenatal influences.

There exists a remarkable similarity between the brain molding and memory building activities of the intelligent ego and the making of phonographic records and moving picture
films. Lifelike impressions of sounds and passing scenes can be made upon the phonographic and photographic mediums only when wax and film are in a highly refined and plastic condition. When impure of substance and coarse of texture they are not sensitive and plastic enough to register and retain the subtle and highly complex vibrations of sounds and passing scenes. In order to receive and register a great variety and complexity of sounds, the wax on the phonograph cylinder must possess a certain degree of refinement, softness and plasticity. If it is too hard and coarse it registers the loud and coarse sounds only. Such a record cylinder, exposed to a beautiful symphony executed by a great orchestra, would register and reproduce only the shrill cries of the trumpet, the rattle of the snare drum and the booming of the big horns and bass drums. The softer sounds of string, wood and wind instruments and finer shadings of tone and rhythm would be lost. With increasing refinement and plasticity, more subtle and delicate sound vibrations will be retained and reproduced.

In like manner the sensitive gray matter of the cortex of the brain must be in a pure and plastic condition in order to receive and register the impressions and impulses coming through the sensory organs, the psychic intuition and the intellectual and emotional activities of the mind. Anything in the way of physical impurity or foreign matter that tends to clog the brain, or to feed it with waste and morbid materials, or with corroding poisons, will lessen the atomic and molecular motility of brain and nerve matter, and will interfere with, or impede, the groupings and subtle transformations involved in the fashioning of brain centers through mental and emotional influences.

If the nutrient blood which feeds the brain substance of the fetus be saturated with CO$_2$, the benumbing, paralyzing carbon-dioxide, with clogging uric acid or the destructive acids of phosphorus and sulfur, the gray matter cannot, respond to the subtle and complex impressions and impulses from without and within.

The purity or impurity of the plastic matrix of the cortex depends upon the materials absorbed from food and drink. If these are so constituted as to create in the system excessive amounts of clogging and corroding substances, then these food and drink poisons will have a benumbing and deteriorating effect upon the sensitive gray matter of the brain, as well as upon the coarser tissues in the joints, muscles and vital organs. There is a rheumatism of the mind as well as of the joints.

A brain asphyxiated and clogged with pathogenic materials cannot be alert and active; it is too dull and lazy to think; it would much rather sleep than work; it is incapable of doing its best when its tiny blood and lymph vessels are obstructed with waste and morbid deposits which prevent the oxygenation and drainage of its delicately organized cellular tissues.
This, of course, is true postnatally as well as prenatally. A brain originally capable of the highest and finest achievements of the human mind may become utterly worthless, and may degenerate into idiocy through food, drink and drug poisoning.

Medical men tell mothers they need not worry over prenatal feeding, because the placenta, the vascular bag which forms the nest of the new life, acts as a filter which purifies the blood before it reaches the fetus. Common sense and every day experience tell another story. Even the best in the blood of many mothers is bad enough to serve as food for the new life.

The placenta does not filter out of the blood of the mother all food, disease and drug poisons. This is proved by the wretched condition of many infants, suffering from malnutrition, anemia and rachitis, after delivery. If the vital fluids of the mother are deficient in the mineral elements, or in other important nutritive substances, how can they deliver them to the fetus?

Occurrences like the following, quite common in our institutional practice, prove positively that the placenta is not a perfect filter for systemic poisons and for disease taints circulating in the blood of the mother.

One of the most pitiable cases of eczema in a little child less than one year old we traced to the fact that the mother, during her first year of marriage, had traveled with her husband through Eastern European and Asiatic countries, and during her pregnancy had been vaccinated five times while passing through localities where smallpox was prevalent. Both she and her husband had always enjoyed perfect health. The family record was excellent as far as traceable; still the body of the infant soon after birth, was covered with open bleeding sores, presenting a revolting sight. We could find no explanation for this strange phenomenon other than the many vaccinations during pregnancy. These had contaminated the blood of the mother, and through her the body of the fetus, with a filthy scrofulous taint.

The baby suffered terribly. For many months it slept but little, because of the excruciating pains. The eczematous eruptions were of a very stubborn nature; they broke forth again and again. Finally, however, after eighteen months of natural treatment, we succeeded in purifying the little body of the horrible infection. The child is now a little over three years old, in perfect health, and during the last twelve months has shown no signs of the morbid taint.

Under another section I shall describe the influence of food upon character and sex life.

To recapitulate: Purity, plasticity and motility of the highly refined and sensitive materials which make up the gray matter of the brain depend upon pure food, plenty of fresh air and exercise, and upon all other natural methods of living.
SECTION XXXV

Conception and Pregnancy

1. Conception takes place whenever the male spermatozoon joins the female ovum (egg) within the woman's womb. Normally the female organism liberates from its ovaries but one ovum each month, usually during menstruation, while the male discharges millions of spermatozoa at each orgasm. Conception does not always follow copulation. The ovum remains in the womb and is capable of impregnation for about five days after menstruation. The spermatozoon on entering the womb may meet an ovum which has been discharged at a previous menstruation, or it may remain alive in the womb for a number of days and finally come in contact with a newly discharged ovum at the following menstruation.

The spermatozoon retains its ability to impregnate the ovum for from ten to fifteen days after its discharge into the womb. When the male and female germs merge into one another, conception or impregnation takes place. As soon as this has happened, the impregnated ovum becomes attached to the inner lining or mucous membrane of the womb and begins its new life as an embryo. The period comprising the time from the impregnation of the ovum until the beginning of labor or childbirth is called pregnancy.

The table of pregnancy on page 377 indicates the probable date of normal termination of a pregnancy, calculated from the last menstruation.

2. Exercise During Pregnancy. Unfortunately a great many expectant mothers labor under the idea that they must rest and be relieved from work and exercise. This of course is a great mistake. Light housework is good exercise. There is nothing more harmful during pregnancy than nursing "that tired feeling" by lounging idly about the house and coddling one's real or imaginary aches and troubles.

Of great benefit to the pregnant woman are all outdoor sports such as tennis, golf and other games which require vigorous exercise without straining or overworking the body. The great benefit of walking and other outdoor exercises, aside from their general invigorating effects, lies in the strengthening of the abdominal muscles and ligaments, which at delivery will greatly facilitate expulsion of the fetus.

The walk should be brisk and rhythmical, body erect, head thrown back, chest forward; the breathing at the same time should be deep and regular. These walks should be continued as long as time and endurance permit. Nothing, of course,
must be pushed to the point of exhaustion. One good long walk every day is necessary; two are better.

We all understand the necessity for a plentiful supply of oxygen under ordinary conditions, and especially in time of illness. During pregnancy the demand for oxygen, as well as for mineral salts, is doubled or trebled on account of the needs of the rapidly developing organism in the womb of the mother.

These extra demands for oxygen and ozone must be supplied by systematic deep breathing, cold bathing, outdoor walks, etc. If circumstances do not permit the taking of outdoor exercise, deep breathing should be practiced as often as feasible, at the open window.

Next in importance among gymnastic exercises is the internal massage described under section XXI, No.16.

Those exercises are especially valuable which bring into play the abdominal muscles and the muscles and ligaments of the genital organs.

3. Clothing. Clothing and the manner of wearing it profoundly influences the normal or abnormal development of the fetus, the health of the mother, labor and delivery.

At no time should the waistline be constricted by a corset or even by the ordinary skirt band. All clothing should be as loose and light as possible—one-piece under and outer garments, with the weight suspended from the shoulders, are best. If skirts are worn they should be fastened to skeleton waists of some thin cotton material. The close, heavy texture of the material from which the corset or so called "reform waist" is made is injurious because it interferes with skin elimination.

Even the slightest constriction of the waist line interferes with the free circulation and the normal blood supply to the abdominal organs, which is of especial importance in pregnancy; it also hinders the free expansion and movement of the uterus during the various stages of pregnancy.

Within the waistline are located a dozen or more important vital organs of the body. Any sort of constriction compresses these organs and pushes them out of their normal position. While this is extremely injurious to the body of a woman under ordinary conditions, it is doubly so to the pregnant mother and to the rapidly growing fetus. Undoubtedly many deformities and monstrosities are produced by unnatural constriction of the blood vessels and vital organs in the abdomen and pelvis of the pregnant woman.

If due attention is paid to the foregoing influences, labor and delivery will be brief and easy. This we have proved in hundreds of cases which have come under our management. The reason why women of civilized countries spend many
hours and sometimes days in dreadful agony of childbirth while those of primitive or savage races, as we call them, produce their young easily and painlessly as the animals do, is that primitive women live more simple and natural lives, while "civilized" mothers violate practically every law of Nature in their daily habits of living.

Civilization unfortunately stands in many respects for that which is artificial, unnatural and therefore productive of disease and suffering in all domains of life, not only as regards physical health, but social and political health as well.

SECTION XXXVI

Danger Signs During Pregnancy

1. Dropsical Swelling. Swelling of the limbs and distention of the veins of the legs during pregnancy may be caused by a tendency towards varicosity, intensified by obstruction of the circulation due to the enlarged uterus. Such a condition requires, aside from the natural regimen, careful and competent treatment.

Swelling of the limbs or other parts of the body may also be caused by incipient or advanced Bright's disease. The urine should be examined from time to time, especially if there is a swelling of the feet and ankles, or if there are dropsical symptoms in other parts of the body.

Such dangerous conditions are usually brought about through the excessive intake of starchy and protein foods which overwork the liver and kidneys and cause pathogenic dogging of the capillary circulation. This may result in uremia attended by violent and sometimes fatal Convulsions.

2. Uremia is the result of retention in the system of waste materials and poisons that should be eliminated through the kidneys and skin. Medical treatment for such conditions, aside from the administration of stimulating drags, consists in hot bathing with the idea of opening the pores of the skin.

We understand that all hot water treatment gives only temporary relief and is followed by greater enervation and inactivity of the skin. The best water treatment for systemic poisoning of any kind consists in the application of wet packs followed by cold ablutions as described in section XV.

The addition to the packs, dry friction rubs, air bath, good massage and neurotherapy treatment will aid in restoring the normal activity of skin, bowels and kidneys.

Whenever the urine contains sugar or albumen, fasting, alternating with raw food diet, is indicated. Suitable regimens are outlined in sections X, XI.
The giving of heavy food to the mother with the idea of increasing the flow of milk is all-wrong. We have found in all cases that the diet outlined in section X will produce a more copious flow of rich milk than lie "nourishing" meat diet. The best remedy for a scanty flow of milk is slow and thorough mastication of a few spoonfuls of raw crushed wheat every day.

3. Morning Sickness. One of the common disorders experienced during pregnancy is that known as Morning Sickness. One suffering from this ailment, though following a natural diet, should sip a cup of hot postum while remaining in bed. If this does not have the desired effect and if the patient has not been accustomed to drinking coffee, half a cup of black coffee with a few drops of lemon juice will quiet the irritated nerves. It is necessary after taking the hot drink to remain in bed for at least thirty minutes. It is understood that this is only an emergency measure. If continued, it will lose its good effect and work injury.

SECTION XXXVII
Labor and Delivery

At about forty weeks, exactly nine solar months, from the period of conception the fetus reaches full maturity, and labor begins. Labor is divided into three stages. During the first stage the neck of the womb becomes slowly and gradually distended and the orifice of the womb opens widely. When this has taken place, the fetal membranes burst and the amniotic liquid surrounding the fetus escapes.

During the second stage the fetus emerges from the womb.

After expulsion of the fetus, the placenta is expelled from the uterine cavity. This constitutes the third stage of labor

The first stage usually begins with more or less radiating pains in the abdomen, accompanied by dull pain in the small of the back and a drawing pain in the limbs. Sometimes women with the first baby feel these pains weeks in advance of the actual commencement of labor. At first they occur at long intervals and are of short duration, but gradually become more prolonged and more frequent. The pains are due to a cramp-like contraction of the muscular apparatus of the uterus forcing its contents downward.

Under this pressure from above, the neck and mouth of the uterus distend to their limits, and the walls become thinner and thinner. First the inner, then the outer orifice of the neck of the womb opens and the fetal membranes protrude and finally rupture, allowing the amniotic fluid to escape. Shortly after this the part of the fetus nearest the orifice, normally the
head, makes its appearance. At the present time the average
duration of the first stage of labor is six hours, but it may last
twenty-four hours or longer, depending upon the plasticity
and elasticity of the bony structures of mother and infant, the
rigidity of the cervix, and the vigor or lack of vigor of the
muscular apparatus of the uterus.

While the foregoing is true of the average delivery under
ordinary ways of living, we find that after the enforcement of
a natural regimen of living during and, better still, before
pregnancy, the entire period of labor and delivery does not
cover more than half an hour, or at the utmost from one to
two hours. Even the disadvantages of slight build and
smallness of pelvis can be overcome by the natural regimen
outlined in section X. When our youngest child was born, the
mother gave the first sign of pain at about midnight. I rose
from bed instantly, but had not time to finish clothing when
the membranes broke. Within twenty minutes after the
commencement of labor the infant was resting in my hands.

The wife of a prominent lawyer in a western city had
experienced three difficult deliveries. Each time surgical
instruments had to be used and she had suffered untold
agonies lasting from 24 to 36 hours. When she became
pregnant the fourth time the most prominent physicians in her
home city assured husband and wife that it was not safe for
her to go through another delivery, that the womb was in
worse condition than ever before therefore they recommended
surgical removal. For conscientious reasons, however, the
husband and wife did not follow the advice of the doctors, but
decided to try natural methods of treatment.

The lady placed herself under our care during the fifth
month of pregnancy. From that time on she followed strictly
the natural regimen of living and received daily the usual
hydropathic and manipulative treatments. This was continued
until a few weeks before delivery. In this case the baby was
born within an hour from the first contraction, and the mother
of the patient, who was in an adjoining room, had not heard a
sound. Many similar experiences refute the idea that it is
unsafe and injurious for pregnant women to undergo the
ordinary methods of natural treatment, such as hydropathic
sprays, sitz baths, massage, Swedish movement and other
forms of manipulation.

1. Preparation for Delivery. The diet during the last week
before the beginning of labor should be very light, consisting
mostly of fruits and vegetables. From the commencement of
labor no food at all should be given, until at least twenty-four
hours after delivery; a three-day fast is better.

In addition to a competent physician, a nurse or midwife
should be engaged. If a good neurotherapist, who has had
sufficient experience in obstetrical work, can be procured, he
should be preferred, because he can assist delivery and make
it much easier by manipulative treatment.
The nurse will make the necessary preparations and provide the various supplies needed in labor. With the first sign of approaching labor, the physician in charge should be summoned. A rectal enema of one pint or more of warm salt water (See. XVIII, No.4) should be administered. The woman should be given a vigorous cold rub and her genitals thoroughly cleansed. She may then remain on her feet and walk about, comfortably dressed, until actual labor commences.

2. **No Anesthetics.** The attending physician should not be impatient to hasten delivery with drugs or instruments. The use of anesthetics should be avoided insofar as this is possible. They should be employed only when absolutely necessary—that is, when excessive pain must be allayed or when surgical delivery is unavoidable.

3. **Breaking of Water Bag.** When the bag of water is about ready to break, the patient is placed in bed. Premature discharge of the amniotic fluid must be guarded against. An escape of the liquid at an early stage means difficult and prolonged labor, commonly known as "dry labor". Usually the membranes burst when the orifice is fully dilated. A large sponge is held in readiness to catch the out-flowing liquid.

3 a. **Umbilical Cord.** When the infant has been delivered, the umbilical cord should not be severed at once. Plenty of time should be allowed for the blood to transfuse itself from the body of the mother to that of the child. This is important. If the connection is severed too soon, the child begins life in an anemic condition.

The newborn baby usually greets the world with a lusty cry. It should be placed on its right side with its face turned away from the mother, care being taken that the cord is not stretched tight. As soon as the cord stops pulsating, plenty of time being allowed for blood transfusion, it is tied about two inches away from the baby's abdomen and cut a little above the ligature. The baby is now wrapped in a warm blanket and put in its crib.

4. **After Delivery.** Immediately after the baby is born, the nurse or attending physician gently compresses the abdomen and womb of the mother, kneading and rubbing it occasionally in order to secure complete contraction and thus prevent hemorrhage. After delivery the mother enjoys a period of rest and recuperation which usually lasts for about half an hour.

5. **Afterbirth.** Meanwhile the placenta becomes detached, and when the pains set in again a few contractions usually suffice to expel it with all the membranes.

The attending physician must make sure that none of it is left in the body, since this might result in putrefaction of the remains and blood poisoning. The woman's genitals should be washed with clean sterilized water.
The exhausted woman should now enjoy a deep, wholesome sleep and awaken from it in a few hours refreshed and strengthened.

In the foregoing I have not gone into the details of obstetrics and of technical management because this must be left to a competent obstetrician. I have called attention only to those points which are of special importance from the viewpoint of Natural Therapeutics and to the differences in treatment between the conventional and natural methods.

6. The Lying-In Period. The lying-in period varies from five to twelve days, according to the constitution of the mother and the care that she has taken during pregnancy. The greatest danger of the lying-in period is puerperal sepsis or blood poisoning. This condition is the result of infection occurring during labor, or it may result from the retention of parts of the placenta.

The only way to prevent this is by observing the most scrupulous cleanliness during the entire process of childbirth and during the lying-in period. When blood poisoning has developed it must be treated the same as all other acute inflammatory diseases (see section IX).

7. Care of the Newborn. The child should begin to breathe immediately after the cord is cut. If it fails to do this, the physician should lift the baby by its feet to facilitate the escape of mucous from the trachea and throat. If necessary the mucous must be removed from the throat by the insertion of the little finger, or by means of a tiny stick covered with gauze.

Breathing may be accelerated effectively by a few sharp taps on shoulders and buttocks. If this fails to bring the desired result, artificial respiration must be resorted to at once. The attendant grasps the child by its shoulders, its head resting between his palms and the two index fingers being hooked under the child's armpits. It is now swung between the physician's legs and lifted high above his head so as to be turned upside down. This is repeated from fifteen to twenty times, after which it is placed in a basin containing a few inches of warm water. Its body should then be rubbed briskly with cold water.

Father Kneipp used to take the newborn babe by the nape of the neck and the feet and submerge it quickly in cold water. This, a few times repeated, is probably the quickest way of resuscitating an asphyxiated baby.

In order to soften the cheesy deposit which frequently covers the body of the newborn, it is well to rub the skin with warm olive oil. After the greasy covering has sufficiently softened it may be removed with bits of gauze. This is followed by a cleansing bath with warm water and castile soap.
After the warm cleansing bath, the little body should be quickly rubbed down with cold water, wrapped in a soft, warm blanket and laid away to sleep until it wakens of its own accord. A normal baby should sleep for about twelve hours, and must not be disturbed to force food on it before it is ready to take it.

8. Bathing. From the first day, the baby must have a morning and evening bath. This consists, as before described, in a quick, cleansing bath of warm water and castile soap, followed immediately by a brisk cold rub. In the course of a few weeks the baby can be placed, for the cleansing bath, in a small bathtub containing a few inches of warm water. Immediately after the cleansing bath the warm water is replaced by cold water. This is taken up in the hollow of the hand and briskly applied to the little body. In this fashion the child, within a few months time, will enjoy its cold rub just as much as an adult. I have seen several such nature cure babies, but a few months old, object most vigorously to a warm bath. The cold rub is the best preventive of chilling; but care must be taken that the temperature of the room where the bath is given is not below 70 deg.

The olive oil bath or rub, often recommended for premature babies or infants suffering from malnutrition, is very injurious, because it occludes the pores of the skin and prevents the elimination of poisonous gases and other morbid materials from the body. The skin is not an organ of digestion. Olive oil, like all other foods, must enter the body through the alimentary canal where, under the action of digestive ferments, it is broken down into its component elements which are then assimilated through the intestinal membranes. Oil absorbed through the skin is not digested, and it circulates in the body as foreign matter which in this state cannot be assimilated and utilized in the system.

9. Powdering after the bath is fully as injurious as the rubbing with oils or massage creams. Powders and creams tend to clog the pores, and most of them contain poisonous antiseptics which lower the vitality of the skin and prevent or suppress elimination in the form of skin eruptions, eczemas, etc. For chafing use nothing but cold water. In case the chafing should become unusually severe and painful, through neglect by the caretaker, a soothing and healing lotion composed of one part lemon juice to two parts olive oil, may be applied a few times, until the irritation is under control.

10. Air Baths. Next to cold water, there is nothing that will invigorate baby’s skin and nervous system as will the air and sun bath. If the season will not allow the outdoor air bath, the baby should be allowed to lie nude several times a day, for thirty minutes or more, in a warm, well ventilated and sunny room.

11. Constipation. Glycerin and suppositories should never be used; neither laxatives nor cathartics. Oat extract and cooling sitz baths will produce natural movements.
12. **Diarrhea** is a form of morbid elimination, and must never be suppressed by drugs. If it is habitual, bailey or wheat extract prepared in the same manner as oat extract, is a good remedy. If the diarrhea is persistent and of a violent nature, no food at all must be given, except water with dilute acid fruit juices, until the purging ceases. Even then plenty of time must be allowed for the rebuilding of the sloughed intestinal membranes.

13. **Bandages.** Until the umbilical cord dries up and falls off, it is necessary to cover the navel with a gauze compress dipped in olive oil. This is held in place by an abdominal bandage made of soft cotton material. These strips should not be hemmed, merely torn or cut. They should be drawn just snugly enough to hold the compress in place, but not tightly enough to interfere with circulation. The navel must be cleansed and the compress renewed twice each day. After the umbilical cord has dropped off we no longer apply the abdominal bandage. This is contrary to common usage, but is the best practice. The abdominal bandage overheats the body and interferes with the free movement of the diaphragm and the circulation of the blood.

14. **Clothing.** The clothing of the infant should be loose and light and as simple as possible. Freedom of movement is very important; binding or pressure upon any part cannot help but interfere with the circulation, and otherwise produce injurious results. The clothes should be short, in order to allow the feet and legs free play. Light weight, porous cotton materials are best for both under and outer garments. A lightweight wool petticoat may be worn when absolutely necessary to provide sufficient protection for the baby. Cotton hose and bootees may be used, but under no circumstances should such articles be of wool, because it prevents free elimination from the skin. The baby's head should not be covered out of doors, except in severe weather. At no time should a veil be placed over the face, as it will cause the infant to reabsorb the poisonous exhalations from its own lungs. All clothing should be changed each day. No garment should be starched—such a practice is not only useless but harmful.

15. **Diapers** must be provided in sufficient number to allow thorough cleansing and drying. The wet diapers should be scalded in hot water and very thoroughly rinsed in several waters afterwards. They should then be dried in the open air and sunshine. Soiled diapers must be well washed and boiled. Washing powders, soda, ammonia and other chemicals should never be used. They have an extremely irritating effect upon the delicate skin of a baby. In order to save labor and to facilitate the cleansing of the diapers, small squares of clean old linen or muslin rags, or pieces of absorbent gauze, may be placed inside. These inserts will absorb all or most of the bowel movement and may then be burned. If the skin is irritated or chafed, the parts should be sponged off with clean cold water at each change, paying special attention to cleansing of the genitals. Oils or powders must not be used to soothe the sore places, because they clog the pores and
Interfere with natural elimination.

16. A wet nurse is to be preferred to artificial feeding. She should be thoroughly healthy, not over thirty years of age, of equitable temper, not excitable or nervous and her diet should be that prescribed for the mother.

17. Care of the Nipples. They should be thoroughly cleansed before and after nursing; not with carbolic acid, but with water and dilute lemon juice. The lemon juice tends also to harden the nipples. Treatment of the nipples may begin before the birth of the child.

18. Care of the Eyes. The baby's eyes, whether awake or asleep, should always be shielded from strong light, either sun or artificial, and from dust and wind. The eyes should be washed with cold water after every cleansing bath. If they show any tendency to weakness or disease, slight vibratory massage over the closed eyelids should be given after the cold eye bath.

19. Care of the Mouth. A healthy baby's mouth needs no cleaning before the arrival of teeth. As a matter of fact, the teeth of a perfectly healthy adult would not need cleaning any more than do those of an animal living in the freedom of nature. The saliva is a sterilizing fluid, under normal living, intended by Nature to keep the mouth clean and healthy. Cleansing of the mouth of an infant with the finger or with a cloth may injure its delicate membranes. If the mouth must be washed, in case of disease, a swab made by twisting a piece of sterilized absorbent cotton on the end of a smooth stick should be used. The swab should be dipped in warm boiled water, and the interior of the mouth washed thoroughly, the cotton then being burned.

20. Care of the Ears. The external ear should be cleansed with a soft rag or swab as before described. Never use a hard instrument inside the ear.

21. Care of the Nose. A baby's nose should be cleansed as a part of the daily toilet, in the same way as the ears. A swab may be made by twisting a, piece of gauze to a cone. As soon as the child becomes old enough, it should be taught to sniff up cold water through the nostrils and the nasal passages. This is the best way to keep the nasal membranes in a clean, healthy condition.

22. Care of the Genital Organs. The genital organs of both sexes must be kept scrupulously clean with as little handling as possible. The foreskin of the penis of the male baby should be drawn back at bathing time and the organ thoroughly cleansed, always finishing with cold water.

23. Phimosis. The treatment of phimosis is fully described under Sec. XXVIII, No.1.

24. How to Lift the Baby. The best way to lift a young
baby is to slip the left hand under the back beneath the shoulder, spreading out the fingers in such a way as to support the neck and head. Then lift the feet and legs with the right hand. Never lift an infant without first supporting the spine.

When a baby has grown strong enough to hold up its head and has gained considerable strength in the muscles of the back and neck, he may be lifted by grasping him with outspread fingers under the armpits; the body must be held firmly so that the entire strain does not come on the shoulders. A baby should never be lifted by the arms. This may dislocate the shoulder joints.

SECTION XXXVIII

Prenatal Feeding

1. Effects of Diet During Pregnancy. The problem of infant nutrition begins before birth. Prenatal feeding determines the physical start in life. On it depends not only the condition of the mother's health during pregnancy, but also the size and weight of the fetus, pliability of the bony structures, ease or difficulty of delivery, and the quality of the mother's milk.

The fleshier and heavier the newborn infant, the prouder and happier are the parents and the doctor. Yet, excessive size and weight of the child constitute the most prominent cause of difficult and painful childbirth and frequent necessity for instrumental delivery.

The biblical saying, "In sorrow thou shalt bring forth children"; has led many to believe that woman's dreadful suffering is a necessity, God ordained; but is not man's ignorance, rather than the cruelty of an avenging God, to blame?

This latter view is confirmed by the fact that other mammalia literally cast their young, without pain or difficulty; and the labor pains of primitive mothers are insignificant, their delivery presenting little more difficulty than that of the lower animals. A squaw on the Western Plains stops a few hours by the wayside to deliver her papoose and then resumes her journey as though nothing had happened.

Women among the European peasantry, who wear no corsets, live on black bread and vegetables, and have plenty of exercise in the fields and in the home to the last day of pregnancy, have their babies without help of midwife or physician and resume their usual routine of work within a few days after delivery.

Thousands of mothers who have adopted natural ways of...
living have learned to dispense with anesthetics and the surgeon's instruments; they now bring forth their offspring without excessive pain.

2. Results of Faulty Diet. It is significant that the offspring of the lower animals, at birth, consist of little more than skin and bones, while the newborn human is often abnormally large and fat. This is especially true of babies born of weak and anemic mothers. As before stated, excessive size and weight of the infant is not a matter for congratulation, but is a pathological condition. It indicates fatty degeneration of the fetus, due to the anemic watery condition of the blood of the mother, and the cause of this hydremia of mother and child lies in the faulty dietetic habits of the former.

The ordinary diet of American women consists almost entirely of meat, fish, fowl, potatoes, white bread, pastry, coffee, tea and refined white sugar. The few vegetable, which enter into the daily dietary are first deprived of their all important organic salts by faulty cooking; fruits are looked upon as luxuries and frequently are regarded as harmful.

The anemic, watery condition of the blood of mother and child is not due to a lack of starchy, protein and fatty materials in food and blood, but to a deficiency of organic mineral elements. Neither is the anemic condition, as the regular school of medicine assumes, caused by lack of iron. Any ordinary food mixture, as well as the blood and milk of anemic mothers, usually contains a sufficient amount of iron. The actual cause of the anemia is a deficiency of other mineral elements.

As I have explained in Volume III of this Series, carbonic acid poisoning and the resulting sluggishness of the surface circulation, coldness of the extremities and congestion of the inner organs is not caused so much by a lack of the oxygen-carrying iron as by a deficiency of the carbonic acid neutralizing and eliminating sodium and magnesium.

If the blood is deficient in lime, phosphates, silicon and fluorine, rachitic conditions, softening of the bones, deformed spines and legs, and decay of the teeth, are inevitable results.

It is an easy matter to supply the daily needs of the organism for proteids, starches, fats and sugars; the difficulty lies in supplying a sufficient amount of the organic mineral elements.

The deficiency of sodium in human blood, Dr. Lahmann proved in the following table of comparative blood analyses. In a hundred parts of ash he found in the

Human blood | 2.03 to 6.27

The percentages of lime and of other positive mineral elements in the human blood are also much lower than in the blood of cows, oxen and sheep.

While the blood of cattle and sheep raised on pasture is very uniform in composition, hardly any two samples of human blood are alike. It is for this reason that Dr. Lahmann adopted cow's milk instead of human milk as the standard elementary food combination.

In the following table, he compares the percentages of minerals in the ash of cow's milk with the percentages of mineral elements in the ash of various other food materials.

A daily dietary consisting largely of meats, eggs, white bread, potatoes, peas and beans, though excessively rich in proteids, fats and starches, will, on account of its deficiency in sodium, lime and magnesium, inevitably result in carbonic acid poisoning, anemia, rachitis, premature decay of the teeth and a multitude of other acute and chronic ailments.

If, however, the daily dietary contains a liberal amount of green vegetables and fruits, a normal food mixture resembling that of cow's milk can easily be obtained. It must be remembered that fruits and vegetables are not only rich in the most important mineral salts, but that they are relatively poor in proteids and carbohydrates.

For this reason fruits and vegetables facilitate the establishment of an equilibrium between proteids and carbohydrates on the one hand and organic mineral salts on the other.

3. Excessive Fat Formation. We can now understand why the ordinary faulty diet of pregnant mothers causes anemia, softening of the bones, sluggish circulation, carbonic acid poisoning and fatty degeneration in mother and offspring.

Lack of sodium causes excessive accumulation of carbonic acid, and oxygen starvation. This results in defective
oxidation of food and waste materials; in other words, in fat formation.

Defective draft prevents the complete consumption of coal, and chokes the furnace with the products of imperfect combustion. Similarly, lack of oxygen in the tissues (due to carbonic acid poisoning) causes an incomplete combustion of food materials and waste products, resulting in fat formation and in the generation of poisonous byproducts.

Lack of sodium also prevents the neutralization and elimination of uric and other acids and ptomaines (pathogenic matter) which accumulate in the tissues, block the circulation and assist in the smothering of the vital processes.

In order to eliminate these pathogenic materials, there arises an abnormal craving for water—"the anemic thirst"—which is closely related to the thirst of fever patients and of diabetics. Excessive water drinking is encouraged by the popular "flushing" fad.

To make things worse, the anemic, for reasons before stated, usually suffers from weak heart action and sluggish circulation. This means defective elimination of water through the skin and kidneys, resulting in a watery (dropsical) condition of the tissues and fatty degeneration.

Not all anemic, carbonic-acid-poisoned mothers, however, develop a tendency to obesity. On the contrary, under certain constitutional conditions, they may become exceedingly lean, like the anemic, carbonic-acid-poisoned consumptive. Briefly stated, sluggish heart action and weak kidneys favor retention of carbonic acid and water in the tissues and thus make for fatty degeneration. Good circulation and normal activity of the kidneys may keep the system free from excess of water and carbonic acid, but excessive proteids in the diet may result in sulfuric and phosphoric acid poisoning. These destructive acids break down the tissues, rob them of their mineral constituents, and thus cause excessive loss of flesh and fat.

In both types of dysemia the blood of the pregnant mother is overloaded with poisonous gases, waste matter and the debris of broken-down tissues. The oxygen supply to the fetus is therefore very much impeded and we find that both fleshy and lean mothers produce babies of abnormal size and weight, ranging from eight to twelve pounds, while the normal weight of the newborn should not be more than six pounds.

4. Advantages of Natural Regimen. We know of many instances where mothers, after having given birth to heavy, fleshy babies, in subsequent births have reduced the weight of the new born to normal, and the pain of delivery to a minimum, by the adoption of a natural diet, plenty of exercise in the fresh air and systematic deep breathing.
The effects of a natural regimen are manifested in various other ways. The bony and muscular structures of mother and child are much more pliable and elastic, making parturition and delivery much easier. Pure blood, normal nutrition and abdominal exercises, walking and special gymnastics, greatly strengthen the abdominal and uterine muscles, thus facilitating expulsion of the fetus.

The morning cold rub, systematic deep breathing and general exercises, every day outdoor walks and right mental and emotional attitude are all of paramount importance in the regimen of pregnancy.

The Regimen for Wholesome Living, section I, is admirably adapted for all the needs of the pregnant mother.

SECTION XXXIX

Postnatal Feeding

Thanks to the educational influence of nature cure propaganda, a decided change for the better in baby feeding has taken place during the past ten years. Up to that time the "top cream mixture" was universally recommended by allopathic physicians and given to babies by trained nurses.

While in the meantime many physicians and nurses have adopted more natural methods, the "top cream mixture" is still too common and must be entirely abolished in order to safeguard the health of our little ones.

In the February, 1909, issue of the Nature Cure Magazine, I commented upon this subject as follows:

1. Bottle-fed Babies. Our food analyses disclose the interesting fact that the elementary composition of the ash of the milk of an animal is about the same as the composition of the ash of its body.

They also show that good cow's milk when normal comes closer to the requirements of the infant body than does inferior human milk.

Our tables of food analyses show that chemically the composition of cow's milk and of human milk is very much the same. Human milk contains a little less proteid and a little more sugar than cow's milk, and the latter is much richer in organic salts than the former. There is much more of the all-important sodium in cow's milk than in human milk and about twice as much calcium (lime) and iron (table p.100). This explains why rachitis is so common among babies, while never found among calves.

As we have learned, the elimination of poisonous acids
from the body depends on sodium. The building of the bony structures depends on lime; the oxygenation of the blood, on iron.

Many years of practical experience in the care of babies has convinced me that milk fresh from a healthy cow is greatly to be preferred, as nourishment for infants, to the impoverished milk of scrofulous mothers.* In this connection it is significant that one-half of all "civilized" mothers, thanks to unnatural food and drink, vaccination and poisonous drugs, are incapacitated for nursing their offspring.

* This may not be true in the future if our milk cows continue to be regularly subjected to tuberculin tests.

To one who has studied the comparative analyses of cow's milk and human milk, it is incomprehensible why the former, when given to infants, should be diluted and spoiled by large quantities of water, salt, soda and inorganic mineral lime (in the form of lime water).

This procedure, however, is still frequently recommended by physicians of the regular school. Undoubtedly, the great frequency of anemic and rachitic diseases, the darkening of the iris, appearance of scurf rim, and the signs of catarrhal conditions in stomach and bowels are caused by such unnatural feeding.

The following extracts are taken from an article entitled "Bottle-fed Babies", in the Ladies' Home Journal. It was written by Dr. Emelyn Lincoln Coolidge, of the Babies' hospital, New York. Thousands of mothers, on account of the high standing and excellent reputation of this family journal, undoubtedly have followed, without question or misgiving, the advice presented.

The formulas given below are for the average healthy baby, and are called "cream" or "top milk" mixtures.

"Food for the first month. With a spoon, or a tiny dipper which comes for this purpose, carefully skim off the top six ounces from a quart bottle of milk; to this add twenty-four ounces of water which has been boiled and cooled, and in which has been dissolved three teaspoonfuls of granulated or six of milk sugar; next add a pinch of bicarbonate of soda and a small pinch of salt; mix this all thoroughly, and pour enough for each feeding into ten separate bottle& Then cork the bottles family with cotton and either Pasteurize the milk or stand it on the ice.

"For the second month. Skim off six ounces of cream, then pour off three ounces of milk; add twenty-four ounces of water and the same amount of sugar, salt and soda as above; mix and bottle.

"For the third and fourth months. Cream, six ounces; milk, six Ounces; water, twelve ounces; barley or oatmeal gruel, twelve ounces; sugar, salt and soda as usual, etc.

Plain Milk Formulas

"Pour the entire quart of bottled milk out into a clean pitcher and then back into the bottle several times, thus thoroughly mixing the milk; then take:
"For the first month. Six ounces of milk, twenty-four ounces of barley-water, half a tablespoonful of granulated or one of milk sugar, a pinch of bicarbonate of soda; mix all well together and pour the proper number of ounces into separate bottles, and either Pasteurize or place on ice.

"For the second month. Nine ounces of milk, twenty-one ounces of barley-water, one tablespoonful of sugar, and a pinch of soda."

Physicians would never think of giving such advice as this, if they were acquainted with natural dietetics founded on exact and complete analyses made by food chemists of the nature cure school.

I have already called attention to the fact that food chemistry, whether practiced in allopathic colleges, in great sanitariums or by vegetarian food reformers, deals with proteids, starches, fats and sugars only, and leaves entirely out of consideration the all important mineral elements or organic salts of potassium, sodium, iron, lime and magnesium.*

*This was true at the time this article was published in the Nature Cure Magazine.)

On these five positive mineral salts, as we have shown, depend all the important vital functions of the human organism, while proteids, starches, fats and sugars serve only as building and fuel material.

The digestion of the proteid and carbohydrate foods, as well as the elimination of the waste matter resulting there from, depends upon the positive organic mineral salts.

Study carefully these recipes for baby feeding, taken from the Ladies' Home Journal, and compare the mixtures with the analyses of cow's milk and human milk in the accompanying tables.

Let us consider the "top milk" mixture, prescribed for the first month. The cream rising to the top is almost pure fat. The all-important mineral elements plus the nourishing milk sugar and proteids remain in the skimmed milk, which is looked upon as worthless and fed to the pigs.

Our food analyses (see tables in Volume III, Cook Book) show that the ordinary brands of flour are almost devoid of mineral elements. Furthermore, one teaspoonful of barley to one pint of hot water does not mean much in food values. Where in these six ounces of cream (fat) and twenty-four ounces of barley water is baby to get the necessary amount of sugar for fuel material, of proteid for tissue-building, of lime for bone-building, of iron for oxygen-carrying, and of sodium, magnesium and potassium for the processes of elimination?

It seems that these deficiencies are intended to be overcome by baking soda, mineral table salt and the lime water, so generally prescribed by physicians. Many times I have demonstrated that inorganic mineral salts, with the possible exception of a little table salt, should not enter the animal or human organism, that these salts must first be organized,
made alive in the plant or animal cell, before they are wholesome food for animals or human beings. I have shown that, taken habitually in the mineral form, these salts accumulate in the human body, act as irritants and poisons and reveal their presence in the iris of the eye.

I fail to understand why the tender and sensitive organism of the newborn infant should be encumbered with inorganic minerals while cow's milk contains them in ideal form, made alive first in the grasses and grains, then still more highly organized and magnetized in the body of the animal.

It is bad enough to give mineral sodium, lime and table salt to an adult, but it is little short of criminal to give them to babies under the guise of foods and medicines.

The cream mixtures are readily digested, because there is not much to digest. The fact that infants thus fed cry for food continually is good evidence that their needs are not satisfied. Babies fed with this sort of slop grow fat for a while. The watery food inevitably produces fatty degeneration. This for a season swamps the little body with unhealthy fat. But the first crisis which happens along often takes away not only the unnatural fat, but the baby also.

The artificial mixtures contain entirely too much water in proportion to nourishing elements. The resulting malnutrition and the constant irritation caused by the inorganic minerals result in chronic diarrhea or constipation.

**The Right Way**

The best food for the newborn and growing infant is undoubtedly the mother's milk, provided that she is herself in fairly good health. Unfortunately, many mothers are unable to nurse their offspring, and if a healthy wet nurse cannot be secured, other food must be provided.

The best substitute for human milk, without question, is cow's milk, fresh, pure and undiluted, as it comes from the animal.

"Why", indignantly exclaims the trained nurse, when we give these instructions, "undiluted cow's milk is altogether too rich, it is indigestible for baby; if the milk is not boiled or pasteurized, germs and bacilli will surely create infectious diseases".

To this we answer: Our analyses show that the difference in composition between cow's milk and human milk is not enough to affect the infant. The danger lies not so much in overfeeding on "rich" cow's milk as in underfeeding on watery milk and cereal dilutions, and in poisoning the little body with inorganic minerals.

As regards germ infection and the necessity for pasteurizing the milk, the menace to health and life is greater through
malnutrition than through germs and bacteria. Germs we
cannot escape, not even if we were surrounded on all sides by
walls of air-purifying and antiseptic materials.*

*Since the foregoing was written we have learned that low
vitality and morbid soil will develop perfectly normal
microzyma into so called disease germs.

One of the foremost French bacteriologists claims that in the
mouths of infants shortly after birth he has found almost every
disease bacillus known to medical science.

William Osler; M.D., to whom the English language is
indebted for the verb "to oslerize," says in The Principals and
Practice of Medicine on page 151, in the chapter on
Diphtheria:

"The presence of the Klebs-Loeffler bacillus is regarded by
bacteriologists as the sole criterion of true diphtheria, and as
this organism may be associated with all grades of throat
affections, from a simple catarrh to a sloughing, gangrenous
process, it is evident that in many instances there will be a
striking discrepancy between the clinical and the
bacteriological diagnosis."

In the first part of this sentence he states that bacteriologists
regard as the sole criterion for the diagnosis of diphtheria the
Klebs-Loeffler, or diphtheria, bacillus; in the last part of the
sentence he admits that this bacillus is found in even slight
catarrhal conditions, and he might add that it is found just as
frequently in the mouth and throat of healthy infants and
adults. This is a good example of "orthodox" scientific
reasoning.

If germs and bacilli of themselves could destroy health and
life, the human race would in a short time become extinct.
Disease germs are omnipresent. They permeate the tissues of
our bodies and in the intestinal tract swarm by millions.
Whether they prevail depends upon natural resistance,
or reserve force, and upon the disease soils in the system. The air
we breathe is saturated with all sorts of disease germs or their
microzyma.

Since baby cannot escape germ invasion, the real problem is
how to increase the resistance of the little organism and how
to purify it of morbid matter so that disease germs will not
find anything to feed on.

Resistance depends largely upon proper nutrition. Diluted,
watery milk, contaminated by inorganic minerals, is not a
good nutrient; its nutritive value is still more reduced by
pasteurizing or boiling. Heating milk or any other proteid food
above 1500 F. coagulates the albumen, disorganizes organic
compounds, precipitates salts and dissipates the life elements.
This reduces the nourishing value and digestibility of the
milk.

Nature does not provide the young animal with boiled or
Pasteurized milk, and we should not lower food values by such methods.*

* It is now admitted that pasteurization and boiling kills "newly discovered vitamins" which are the "life elements" constantly referred to in my earlier writings.

I do not wish to intimate, however, that scrupulous care and cleanliness should not be exercised in the selection and handling of the milk.

Wherever possible, secure the milk of a single healthy cow that grazes on green pastures or is fed on normal clean food mixtures. Milk from cows kept in stables and fed on brewery and distillery slops and other refuse should not be used.

Every vessel and utensil with which the milk comes in contact must be carefully scoured, submerged in boiling water, drained and kept in a light, airy place.

The nursing bottle, after each feeding, must be taken apart and carefully scrubbed, inside and out, in hot water with an addition of a little soda. It should then be left in pure, cold water, until the next feeding time.

2. When to Feed. Physicians quite generally recommend feedings at stated hours, in fixed quantities.

This is altogether wrong, it establishes at once the stuffing habit, does not permit the development of natural desire and its regulation. The infant very soon becomes accustomed to eating at certain times, whether it really needs the food or not.

Food should not be given until there is an actual demand for it, which will express itself in real hunger. By careful observation and experiment the mother will soon learn to distinguish the ordinary crying of the baby and the desire for food expressed by it. If this practice of feeding only when there is a natural desire for food is strictly followed, the infant will soon establish its own regular feeding times, usually at intervals of about three or four hours in the daytime. The stomach digestion of a feeding of milk will require about three hours, therefore a minimum of that much time should be allowed between feedings after the first few weeks.

If the mother can nurse her baby, it should be put to the breast upon awakening from its first sleep, either before or after bathing and dressing.

The first secretion of the breasts (colostrum) is not really a food, but performs an important function in cleansing the intestinal tract and preparing the digestive system to properly digest and assimilate the milk when it comes, usually about the third day.

3. How to Feed. If artificial feeding must be resorted to, no food at all should be given, except a few teaspoonfuls of water, during the first twenty-four hours after birth. During
the next few days, cow's milk should be given, well diluted—about one-half milk and one-half filtered or boiled water. From week to week the amount of water should be reduced until at the end of the second month the baby takes cow's milk undiluted.

4. Night Feeding. In the nighttime feeding should not be encouraged. During the first four months it is advisable to feed not more than once during the night. After that the child should be weaned from the habit entirely. This will be facilitated by giving a drink of water instead of milk.

5. Amount of Food. Discretion should be observed in determining the amount of food. Do not induce the baby to take as much as possible, rather as little as possible. Its welfare does not depend upon the amount of food consumed, but upon the amount which it can easily digest and assimilate.

When more food is given than the digestive organs can take care of, the entire mass may ferment and sour.

6. Grain Extracts. If undiluted milk proves too rich, grain water may be added. In order to prepare this, take clean grain as it comes from the field, crush it in a hand grain mill or a new coffee mill, take three tablespoonfuls of the crushed grain to one pint of cold water, and boil on the stove for one hour; or in the fireless cooker for two or three hours, in which case use a little more water at the start. While the gruel is boiling over the fire, add enough water to allow for evaporation and absorption. When thoroughly cooked, strain the gruel through a fine cloth or sieve. Add one tablespoonful, or more if necessary, to each milk feeding.

When baby is constipated, add to the milk, grain extract made from oats, and frequently cool the bowels with cold water. This will cure the most stubborn constipation. If the bowels are too loose, add to the milk, extract made from barley or wheat.

The small particles of hulls in the grain extracts improve digestion and evacuation, in a mechanical manner. They permeate the curds and keep them from coagulating too solidly, thereby facilitating the penetration of digestive juices; they also exert a mild stimulation on the walls of the intestines, thereby increasing the peristalsis of the bowels and evacuation of feces.

7. Baby's Natural Medicines. Fruit juices and scraped raw ripe pear or apple and the pulp of cooked fruits such as prunes or figs without addition of sugar or sweetening of any kind, are baby's finest medicines. They increase the supply of organic salts for blood, nerve and bone building and for purposes of elimination. They are nature's own chologogues, laxatives, tonics and antiseptics. They keep the little body sweet and wholesome. All babies under our care receive fruit juices beginning with the second week.
During the first two months, give one teaspoonful of orange juice, grape fruit juice or prune juice, one hour before or after each nursing. After the second month, gradually increase the amounts of fruit juices and begin to add raw pear or apple scraped with a spoon or dull knife, or the mashed pulp of fully ripened peach or grapes.

8. Weaning the Baby. Nursing infants should be weaned from the breast after the eighth or ninth month. From the sixth or seventh month, both nursing and bottle-fed babies should begin to take some solid food. The best of these to begin with are whole-grain cereals, gruels, raw and cooked fruits and tender vegetables in small amounts. Mealy baked potato is one of the best foods, better than the cereals.

9. Feeding After First Year. After the lapse of the first year, the solid foods are gradually increased and the milk reduced in quantity. Eggs should not be given before the eighteenth month, then soft-boiled or poached. During the second and third year half an egg twice or three times a week is sufficient; after that an egg at a time may be given once or twice a week.

Meat and all other foods prepared from the dead animal carcass are bad enough for adults, but it is inexcusable to give them to tender infants and children.

Dog fanciers, when they sell a valuable canine, usually advise the buyer not to give the animal any meat before the second year, lest it become a victim of distemper; and dogs are naturally meat eaters.

Well informed physicians now generally advise not to give meat to children before the fifth or sixth year. They have learned this much from the nature cure people.

Foods undoubtedly have a powerful influence, not only on the physical body, but also on the mentality and the emotions. These problems will be interesting subjects of investigation for the food chemist and psychologist of the future. In general, we may say that flesh foods are stimulating and feed the passionate nature, while fruits and tender vegetables refine and stimulate brain and nerve matter as well as the intellectual, emotional and spiritual activities. Cereals, nuts and pulses build and repair the physical body and supply the body with heat and muscular energy.

The majority of animals adhere strictly to one kind of food, and therefore faithfully exhibit in their mental and emotional characteristics the effects of different food materials. Ferociousness we find personified in the carnivorous bulldog, lion, tiger and panther (that is why soldiers are fed on meat three times a day); gluttony and omnivorous voraciousness in the hog, chicken and hyena; cold-blooded cunning in the fox, and cruelty in the cat. The intelligence of the carnivorous animals displays itself mainly in the cruel cunning with which they stalk their living prey. It resembles in quality the low
intelligence of the human criminal.

Personifications of great physical strength, intelligence, endurance, patience, gentleness, fidelity, affection and self-control, we find among the vegetarian animals. The beaver, the arboreal ape and the elephant are especially noted for their intelligence; deer, antelope and sheep for gentleness; the horse for its almost human intelligence, affection and fidelity; oxen, elephants and camels for their great strength and endurance.

Meat is detrimental to the child in every way, physically, mentally and morally. The poisonous acids and alkaloids which it contains clog the capillary circulation, causing anemia, coldness of the extremities and defective elimination through the skin. This results in congestion in the interior organs, high blood pressure in brain and heart, headaches, nervousness, irritability, tendency to fevers, inflammations and catarrhal conditions.

With the meat, the child often absorbs the eggs of worms, tubercular bacilli, and other parasites and disease germs. Certain forms of epilepsy, St. Vitus' dance and hysterical conditions are due to uric acid poisoning and to other pathogenic materials and ptomains contained in flesh foods. Such patients, in times of crises, frequently emit pronounced odors of raw meat or uric acid. Strictly vegetarian diet, combined with other eliminative natural methods of treatment, cures the majority of these cases.

Most of these poisonous acids, alkaloids and ptomains contained in the flesh of dead animals are powerful stimulants. I have frequently noticed that people who have abstained from meat for a long time, when they first partake of it again experience sensations and exhibit symptoms resembling those of alcoholic intoxication.

We have learned that these stimulating extractives of flesh foods chemically closely resemble caffeine, thein and nicotine. The use of one or more of these stimulants invariably creates a craving for the others. This explains why a heavy meat eater is usually a confirmed coffee drinker or invertebrate smoker, and vice versa; and why we find it almost impossible to wean people from one of these stimulants as long as they persist in taking the others.

The legumes or pulses—peas, beans and lentils—are close seconds to meat in acid-producing qualities. Eggs contain considerable ready-made uric acid and a great deal of sulfur and phosphorus. These may become dangerous to the organism. For these reasons, meats, legumes and eggs are always danger foods for the child.

Children brought up on such foods will show the effects in nervousness, irritability, lack of self-control, craving for cigarettes and alcoholic stimulants. The most serious aspect of this question lies in the stimulative influence of meat poisons.
on the sex centers. It is a well known fact, verified by close observation, that flesh foods stimulate the sexual passions to a marked degree. This tendency is greatly increased by the use of coffee, tea and alcoholic stimulants in the form of wines, liquors or medicines. If the sensitive nervous organism of a child is overwrought by these powerful irritants, there can be but one result; precocious sexual awakening.

From the third year the child may gradually adopt with slight appropriate modifications, a diet as outlined under Sec. I, No. 10, and Sec. X, No. 7.

SECTION XL

Exercises in Infancy

1. Exercises in Infancy. Proper exercise is important from the very beginning of life. A baby will follow its natural instincts for exercise if allowed to do so, by working its arms and legs and writhing its little body in all directions, if not unduly hampered by tight clothing and bandages. A few nude air baths every day will afford excellent opportunity for baby's gymnastic stunts.

After he is a few months old he may be placed on his stomach, when he will exert himself vigorously by trying to raise his head, to turn around, or to raise himself with his arms. He will soon learn to roll over and to creep lie nay now be pulled up gently by his arms and lowered again a number of times in succession.

When three or four months old he may be lifted by one arm or by both arms; by the right arm and left leg, or by the left arm and right leg. When the baby is six or eight months old, he should be strong enough to rise from his back to a sitting position. This may be encouraged by holding down the feet. I have known a number of nature cure babies who at six months of age clung tightly to a stick while being lifted a few feet from the bed. Another good exercise greatly enjoyed by the youngsters is to roll them back and forth on a bed.

The average healthy child will secure ample exercise while learning to walk and run and while playing with simple toys or with other children; but this may be supplemented to good advantage by special exercises devised by the father and mother. Nothing is better for the health and happiness of both parents and children than to join in merry romp and play.

Between two and five years of age the child may be taught more difficult stunts, performed either by himself or with the assistance of the father or mother; but swinging the child high overhead, throwing him up and catching and other dangerous tricks should be avoided. They are risky and have very little effect in developing the body of the child. The best exercise at this age consists in outdoor play and games.
From the sixth year, the question of exercise becomes a more important one, especially since the children are confined for many hours in school rooms. If exercise at this time of life, through play and games and special gymnastics, is neglected, it may affect health, strength and efficiency of the child for life.

Those of good physique and ample strength may gradually take up and practice the exercises for adults outlined in sections XXI, XXII, XXIII, XXIV.

2. **High Chair**. A baby should not be put in a high chair until he is quite well able to hold the spine and head erect, and should never be left in a chair for any length of time. If a baby is forced to maintain a rigid, sitting position for a considerable time, before the bones and muscles are sufficiently developed, this may produce deformity of the spine. Maids and nurses, if not properly supervised, sometimes fasten a baby in a high chair and leave him there to take care of himself for long periods.

3. **Toys**. Since most babies have a habit of putting everything into their mouths, toys must be selected that can do no harm. They should have no paint, no sharp points or corners which might hurt the eyes or mouth, and must be of material which can be easily and thoroughly cleansed. Hairy and woolly playthings are unsafe, being unclean and germ carriers. Objects small enough to be swallowed must never be put within baby's reach. The simpler the playthings the better; a few clothespins, empty spools, or other simple objects are better than expensive toys.

**SECTION XLI**

**Baby's Ailments**

1. **Hernia**. As a result of a weakly or sickly condition of the mother during pregnancy and of faulty prenatal management, many children are born ruptured. So far I have not known a single nature cure baby that was born ruptured. Such defects are due to weakness of the tissues. This results from mineral starvation. The tissue walls contain too much mortar (protein) and not enough building stone (mineral salts). Prevention of hernia, therefore, lies mainly in proper diet of the pregnant mother, but all the rest of the prenatal regimen described in these pages is of great importance in preventing this and other ailments and deformities.

There are three principal points at which rupture or hernia may take place in infancy-at the navel, in the groin, and at the line between the navel and the lower end of the sternum. Other kinds of ruptures are extremely rare.
2. Umbilical Hernia  This is a protrusion of the intestine at the navel. It is the most common rupture in infancy. Pulling on the cord during childbirth, urging at stool or violent crying may result in rupture. The umbilical ring first expands and this forms a pouch into which one of the folds of the small intestine protrudes.

Treatment: Of primary importance is the diet as outlined herein. The baby must have plenty of fruit juices in order to reinforce the mineral salts in the milk. Cold bathing is very beneficial. The rupture itself should be cleansed several times a day with warm water. This must be followed by a wash with cold water mixed with lemon juice. Gentle, passive exercise, such as raising, lowering and twisting the limbs from side to side, also raising and lowering the body while supporting the shoulders and head, is of especial value.

The rupture must be reduced and kept from protruding by placing over it a large button or other article of similar shape, wrapped in gauze and held in place by broad strips of adhesive plaster. The adhesive tape is fastened over the button crosswise and must be applied in such a manner as to draw the skin from all sides over the rupture. Instead of the button, a compress made of gauze may be laid over the rupture and held in place by one broad adhesive strip. The covering of the rupture must be removed and renewed every day in order to allow cleansing, as before described.

When the child is old enough to exercise by himself, he should be taught special movements of the body and the limbs which develop the muscles of the abdominal region.

3. Ventral Hernia. This occurs along the middle line of the body between the navel and the breastbone, sometimes below the navel. The rupture may not be larger than the size of a pea or small marble, and may disappear on pressure. The treatment is the same as that of umbilical hernia.

4. Inguinal and Scrotal Hernia  occur in infancy or in adult life; sometimes the inguinal canal does not close after the descent of the testes from the abdominal cavity into the scrotum, and the intestine descends through the open canal, thus producing the rupture. These forms of hernia become aggravated by coughing. They can be reduced immediately with gentle manipulation while the patient is lying on his back. This kind of rupture may be distinguished from hydrocele by the fact that in reducing it goes back easily with a gurgling sound. Hydrocele is not affected by coughing. A hernia is opaque to transmitted light; hydrocele, transparent.

These ruptures should be protected with a well-fitting truss. This has to be removed daily for cleansing of the parts. Appropriate exercises, passive and active, together with cooling sitz baths and washes with cold water and lemon juice are the best remedies for these, as well as of other forms of rupture.
5. **Congenital Hernia** occurs in the form of inguinal hernia and has to be treated in the same way. Ruptures of any kind must be reduced and properly supported. Constipation and consequent urging at stool may cause or aggravate any form of hernia and must, therefore, be overcome by the right treatment described under section XXVI, No.1.

6. **Colic.** This is usually caused by indigestion due to overfeeding, improper feeding, or too frequent feeding. The intestines are distended with gas, giving rise to a severe pain. The baby cries sharply, alternately drawing its legs up to the body and kicking them away. One of the quickest means of relief is a small enema of warm water and gentle circular massage of the abdomen from right to left. Food should be withheld until the symptoms have disappeared. The giving of milk or other food may quiet the attack temporarily, but the pain is apt to return with greater intensity. Warm water may be given if the baby will swallow it.

A baby managed in the natural way prenatally and postnatally is not likely to suffer from this ailment. Constipated babies are more prone to it than others.

Colic may also be caused by sudden chilling. In that case a warm bath for five or ten minutes, followed by gentle body massage will bring about a warm reaction.

7. **Convulsions.** These cause a great deal of anxiety to the fond mother. They are always reflex symptoms of some slight or serious internal disturbance due to wrong management. They commonly result from some form of auto-intoxication caused by digestive disturbances, and the resulting systemic or drug poisoning. An inactive condition of the skin, bowels or kidneys will favor auto-intoxication and convulsions. If proper care is taken to keep the system pure, and the organs of elimination in active condition, convulsions will not occur.

The best treatment during an attack is a quick, cold rub all over the body; application of a whole body or trunk pack; gentle soothing magnetic massage, and neurotherapy treatment. These treatments draw the blood into the surface and relieve congestion in the brain and nervous system.

8. **Ailments of Teething.** Many ailments of children are laid to teething, but this is a mistake. Well managed, healthy babies go through the teething period without any trouble whatsoever. This is practically always true of nature cure babies. When, however, the little body is heavily encumbered with hereditary and acquired morbid materials, food poisons and disease taints, the process of teething will not run its natural course and may precipitate any form of disease crisis.

When teething is difficult, it is frequently associated with digestive disturbances. Diarrhea may alternate with constipation and vomiting is of common occurrence. The baby may be restless and fretful. He tries continually to bite on something in order to facilitate the projection of the teeth
through the hardened gums.

No teething lotions or soothing medicines of any kind should be given for the relief of pain in teething. They all contain poisonous sedatives which benumb and paralyze the nerves and have serious after effects upon the system. They usually contain opium in some form, or other narcotic drugs.

The only way to prevent these and other infantile ailments is to keep the little body as nearly normal as possible through the natural treatment described in these pages. If this is closely adhered to, it will prevent, in many cases, the development of even measles and other common eliminative infantile ailments.

During this critical period in the baby's life the diet must be extra light; starchy food should be reduced to a minimum and replaced by raw and cooked fruits and vegetables juices. Cooling sitz baths will help to keep the bowels active and to abate internal fever.

9. Acute Catarrhal Disease. Acute catarrhal diseases of infancy such as croup, cold in the head, acute bronchitis and whooping cough, are different forms of acute elimination through which Nature tries to purify the little body from hereditary and acquired accumulations of morbid matter, systemic poisons and disease taints.

In accordance with this conception of acute diseases, as purifying, healing efforts of Nature, we would not do anything to check or suppress elimination but cooperate with Nature in her purifying, healing efforts. How we do this has been fully explained in other parts of this volume. (Section VIII)

The natural treatment is very much the same in all acute inflammatory ailments. Feeding must be reduced to a minimum. If the baby does not insist upon eating, nothing should be given except water with acid or sub-acid fruit juices, such as lime, lemon, grape fruit and orange. If the temperature does not run high, say not above 100 or 102 deg, frequent ablutions with cold water at intervals of from one to two hours will be sufficient to promote heat radiation and elimination of morbid matter through the skin and other organs of elimination. If the temperature runs' higher, say between 102 and 105 deg, wet packs must be applied, and renewed when they become hot or dry.

The wet packs are of especial value in all kinds of cough; whether it be the ordinary cough, croupy cough or whooping cough. A whole body or trunk pack, with or without a throat pack, will give almost instant relief. In many instances where baby is making the night hideous for the anxious mother, with it's coughing, a well-applied whole body pack, or a combination trunk and throat pack, will relieve the coughing almost instantly, and induce restful sleep.
In serious cases it is always advisable to call in a natural therapist or some other drugless physician, if one can be reached.

The mother should not forget that all acute diseases, after they have once developed, must run their natural course. She must, therefore, not become impatient and lose faith in the natural treatment if it takes a week or more to cure a common cold in the head or an attack of bronchitis, or if it takes from two to eight weeks to cure a case of whooping cough. Serenity, patience and cheerfulness are the primary requisites of the nature cure physician.

PART IV

BABY BOOK

Natural Therapeutics has undoubtedly solved the problem of treating human ailments. All other schools and systems will in time have to adopt the natural way. It is the hub of the healing art; all therapeutic methods radiate from it like spokes from a wheel.

Natural Therapeutics, however, has something better to give than treatment of disease, and that is prevention of disease. If children were brought into this world in the manner ordained by Nature and reared in harmony with the teachings of natural philosophy, disease would soon be a thing of the past. Human beings would then enjoy good health and be as beautiful and perfect in their kind as are animals, which live in the freedom of Nature, guided by instinct and therefore in harmony with the laws of their being.

We must begin, then, with prevention, for prevention is always easier and cheaper, than cure. But where must we begin to study the prevention of disease? Some will say, "At birth, because that is the beginning of life." Not so: that would be too late. The mould is made and the foundation laid for health or disease, for happiness or suffering, for efficiency or deficiency, before the human being in process of creation sees the light of day.

"Then," it may be said, "we must begin with prenatal influence, for the physical, mental, emotional and moral habits of the mother influence powerfully the development of the new life she is carrying." True—but we must start earlier than that. The making of the human being begins with mating and conception. All subsequent development depends upon the right start.

SECTION XXXII

Heredity

1. Importance of Correct Mating. Of primary importance in the sacred rite of procreation, as already intimated, is mating. This should take place only between descendants of the same subrace, or of closely related subraces such as the Indo-Caucasian and Celtic.

If the racial descent of the marriage partners is so far removed that it has produced pronounced differences in racial
characteristic—as in the case of the swarthy Mexican and white skinned Englishwoman, or the dark eyed Magyar and blue-eyed Scandinavian—then procreation becomes miscegenation and degenerates into mongrelization of the offspring. Everywhere in the animal and human kingdoms Nature has set the mark of disapproval on the mongrel. The offspring of miscegenation is doomed to deterioration and extinction unless assimilation of the elements of a lower race by a higher takes place sparingly and gradually.

The law of racial purity may be summed up as follows: When a member of a higher race cohabits with a descendant of a lower race, the offspring of the union loses more or less the characteristics of the higher race and reverts in physical, mental and moral traits to the level of the lower race.

The constructive results of racial purity are evident in Hindus of the higher castes; in that portion of the Jewish race which in mating has faithfully adhered to the Law of Moses, and in the blond and blue-eyed remnants of the Indo-Caucasian and Celtic races in Northern Europe and North America. The destructive results of miscegenation are plainly evident in the mongrelized population of Mexico and everywhere in the half-breed and many kinds of mixed breeds. These usually fall below the physical, mental and moral standards of the parent stock, and almost invariably revert to the customs and habits of the inferior race.

2. Use Heredity. Use heredity deals with the transmission to offspring of acquired physical, mental and moral characteristics of the parents. According to this law as it has been formulated, the chances of the offspring for long life, health, mental efficiency and moral stamina, other conditions being favorable, are better in direct ratio to the advancing age of the parents at the time of conception. While this is contrary to popular opinion, which assumes that younger parents produce more perfect offspring than older ones, the fact of use heredity is proved, both in the animal and human kingdom, by common observation and statistical evidence.

The working of the law is based on the fact that the procreative elements of the parents, or rather the microzyma of those elements, cannot contain the impress of physical, mental and psychical characteristics which at the time of procreation were not developed in the threefold organisms of father and mother.

The age of the father at conception is called the "birth age" of the offspring and determines its birth rank. While the father and previous male ancestors, for reasons hereafter explained, seem to exert greater control over the mental and physical characteristics, the mother furnishes the nutrient soil for physical growth. This does not mean that she exerts no control over the mental and psychical characteristics of the offspring; in addition to her influence through use heredity she has added opportunities through prenatal influence and postnatal training.
According to this law, then, the chances of the offspring for excellent physical, mental and moral development become better as the age of the father at the time of procreation advances beyond thirty five; while the physical condition of the mother for reproductive function is best below thirty five years.

But we must not overlook the fact that too great a discrepancy of age between the man and woman may become the cause of physical and mental incompatibility, of aversion and great unhappiness, especially on the part of the younger woman.

Extensive statistical evidence seems to prove that the birth age of the mother has been of less importance than that of the father. As will be shown in Natural Eugenics, the majority of famous men in all lines or human endeavor had old male ancestors, while the mothers and previous female ancestors were of much younger age at the time of conception.

This may be accounted for by the following reasons:

The man is usually considerably older than the woman at the time of marriage. Men, as a rule, devote much more time and effort to acquiring a scientific, professional or business education than do women. This has been true in the past more than it will be in the future. Thrown early into the competitive struggle of life men generally have had to make greater mental and physical effort than have women.

These points are of considerable importance because it has been proved that it is not inherited brain mass and mental capacity, but strenuous and persistent effort that intensifies use heredity. The earlier this begins and the longer it continues before procreation takes place, the better the chances of the offspring for physical, mental and moral capacity.

The reproductivity of the mother has usually ceased at thirty-five. Though she be capable of childbearing a few years longer, usually conception has been avoided after that age. Men under favorable conditions remain reproductive to advanced age. Some of the world's greatest men descended from fathers over sixty years old.

That intellectual and creative capacity has followed the male line of descent rather than the female line, is indicated by the fact that the high intellectual capacity of many eminent men has skipped their daughters to reappear in male descendants. This may be partly accounted for by the fact that the daughters in their limited spheres of activity have not had the opportunity to unfold inherent intellectual capacity to any conspicuous degree.

There has been a tendency in some quarters to criticize the general entrance of women into professional and commercial life and to dilate upon the adverse influence this will have
upon womanly characteristics and family life.

In the light of the knowledge we possess upon the subject of use heredity, it is safe to say that any such problematical drawbacks will be far outweighed by the general postponement of the marriage age. This will insure not only better physical fitness but also higher intellectual development and greater moral stamina on both sides of parentage.

The tremendous benefits which this increased hereditary endowment will confer upon future generations cannot be overestimated. Greater intellectual and economic equality between the sexes will emancipate woman from degrading sexual subservience. Under the old order, sex appeal was too often her only stock in trade by which to attract and hold the male and thus to secure a living. Economic independence will insure greater consideration and higher esteem for the woman on the part of the man. It will go a long ways toward solving the problem of birth control in a natural way, by leaving it more largely to the judgment of the mother.

We find the law of use heredity according to birth age verified in the intelligence and moral development or obliquity of races, nations and tribes all over the earth—The lower the average birth age of a race or nation, the lower, other things being equal, the intellectual and moral development The greatest development and efficiency is found among those nations where marriage is delayed to a later age through custom, economic necessity, professional or military training.

The following quotation from "Control of Heredity", by Casper Lavater Redfield, is of interest in this connection:

"In general it may be said that wherever there are no restraints upon the sexual propensities, as with the Digger Indians, the Fuegians, the Andamanese, the Wauraus of the Guianas, the Bushmen and the tribes along the Gabbon river, there we find reproduction taking place at the earliest possible age, and the lowest grade of intelligence. Where we find some special circumstances or customs that delay the age at which reproduction takes place, as with the Patagonians, the North American Indian and the Polynesians, there we find considerably higher grade of intelligence.

"Where we find the custom of marrying late in life, as was customary with the Greeks and the Romans, there we find a very high grade of intelligence. And where we find a fortuitous succession of very late births, there we find the very great men of the world's history.

"In other words, the longer the time in which the individuals have in which to use, develop and strengthen their brains before reproduction begins, the greater and more powerful are the brains of their descendants."

In Volume IV of this Series I shall quote elaborate and
highly interesting statistics from Redfield, which reveal the
effects of the various birth ages on physical, mental and moral
characteristics. I shall confine myself, for the present, to the
statement that, with few exceptions, the great artists,
scientists, philosophers, statesmen and philanthropists were
born from fathers whose ages ranged from forty to sixty-five
years at the time of the procreation of their famous offspring.

The existence of these laws and principles as facts in nature
is very evident in the training of racehorses and of other
animals along certain lines of proficiency.

3. Pernicious Heredity. The effects of deteriorating and
destructive heredity prenatal and congenital influences have
been traced and commented upon in so many different ways
that I do not believe it necessary to enter deeply into this
phase of the subject. Various authors have filled entire
volumes with the unsavory family histories of the descendants
of the Jutes, Ishmaels and other drunkards, prostitutes,
degenerates and criminals, which prove positively the
transmission of morbid and pernicious traits through
successive generations. It has been proved statistically beyond
the shadow of a doubt that youthful delinquency, pauperism
and criminality are the aftermath of immature marriages.

The laws of use heredity and prenatal influence, like all
other natural laws and principles, manifest along opposite
lines of expression. It remains for us to determine whether we
shall align ourselves with their destructive or constructive
activities. The effects upon ourselves and our offspring will
show accordingly.

If I succeed in arousing the consciousness of prospective
fathers and mothers to the glorious privileges and enormous
responsibilities which these laws of nature confer upon them,
then my labor will not have been in vain and I shall feel
deeply gratified.

SECTION XXXIII

1. The Creative Alchemy of Love and Affection

Procreation—as is the case with everything else pertaining
to the constituents and functions of the human entity—takes
place on three planes of being, the material (physical and
spiritual), the mental and the psychical planes. Which of these
elements shall predominate in the offspring depends upon the
mixture and adjustment of qualities in the triune makeup of
the mating couple. In order to fulfill the law and to draw the
divine blessing upon themselves and the fruit of their union
the partners in the procreative function must be united by the
bonds of love, or at least by the ties of true affection.
The source of creative genius is love and wisdom, and the essence of intelligence and power is sincerity and goodness. Without these, intelligence degenerates into selfish cunning, power into self-destructive brute force. The spring cannot rise higher than its source; its water cannot be pure and wholesome when contaminated by impure admixtures from filthy surroundings.

It is not generally known that use heredity pertains to intellectual and psychical qualities, as well as to the physical material. Animalism breeds nothing but selfish animalism. The vampire who craves and absorbs the love of its victims and robs them of vital energy, without being capable of feeling or bestowing affection, is the child of a discordant union—of brute animalism on the part of the man, of secret aversion and hatred, usually, on the part of the woman. These bestial and degrading tendencies on the one side, and unrequited love craving on the other, breed sex perversion, and propagate the harpies who delight in the seductive power of superficial beauty, while gloating over the weakness and ruin of their victims.

True love and affection, paired with intelligence and goodness; liberate the creative elements necessary to the production of perfect offspring.

The finer qualities of mind and soul open the fountains of life on the higher planes, liberate and harmonize the male and female procreative fluids, and charge them with the purest and most potent intellectual, spiritual and psychical elements.

The divine fire of creative genius burns only in the love aura of truly mated couples. It is true that these are rare under our artificial, unrighteous social institutions, and that accounts for the rarity of complete manhood and womanhood.

Perfect offspring, endowed with beauty and power of body, mind and soul, destined to shed through life a radiance of health, happiness and helpfulness— to love and be loved—issues only from the union of love and affection with intelligence and goodness.

"Love lieth at the foundation" (of all that is). "Love is passion, enthusiasm, affection, heat, fire, soul—God."

To the extent that love enters into the holy rite, to that extent its attributes will be absorbed in the threefold organism of the woman and become active in the child building in her womb. While she loves her man more than ever, her most passionate affection is centered in the new being in process of development. On it she bestows the purest and best in her food and drink, in her thoughts, emotions and secret desires. Fear, worry, anxiety, jealousy and hatred are strangers to her soul; these are the emanations of the lower spheres—she lives in heaven.

Somebody endowed with deep insight into these matters has
said:

"Whatever male and female shall truly will for, hopefully pray for and earnestly yearn for, when love pure and holy is the nuptive ascendant, in form, passionate, affectional, divine and volitional, that prayer shall be granted, and the boon be given—but the prayer must precede."

What are the direct effects of the marital rite upon the participants? If the sex attraction operates on the physical material plane only, if lust instead of love presides at the matrimonial feast, then temporary gratification of erotic craving will be followed inevitably by monotony, satiety, gradual revulsion and aversion, culminating in a morbid craving for change and variety. The partners in carnal self-indulgence are intuitively aware of these tendencies to marital unfaithfulness, and, therefore, easily dominated by distrust and jealousy.

The procreative function is attended by complete satisfaction, buoyancy of body and mind and lasting happiness only when sex attraction operates on the higher and highest planes of being, as well as on the lower; when desire and impulse are operative on both sides. Thus only will the generative function fulfill its sacred purpose and confer the highest possible benefits upon parents and offspring.

The woman, being the more highly sensitized, must be responsive to the call of holy passion. To force unwilling compliance will ruin the woman, kill her love and curse her offspring. Balzac says: "He who begins with his wife by a rape is a lost man." It is impossible for a wife to love unless she is won, not forced to compliance.

2. Sexual Intercourse During Pregnancy. Sexual intercourse should be considered the most sacred function of the human entity. From the highest and best viewpoint it should be exercised only for the propagation of offspring. However, considering the present stage of ethical and moral development, temperate indulgence may not be wholly condemned. Excessive intercourse is always weakening and harmful to both participants. We must remember that the sex fluid is the carrier of the life force. It is that which constitutes strength, resistance to disease, initiative and genius. During abstinence from intercourse the sex fluids with their creative energy are absorbed through the inguinal glands into the organism and increase physical, mental, moral and spiritual capacity and energy.

Set rules for frequency of intercourse cannot be given. This must depend entirely upon individual conditions. One safe rule is that after indulgence there should be no feeling of satiety, weakness and exhaustion. The more frequent the indulgence the stronger will grow the power of habit and of passion and the greater will become the abnormal craving. It is the same with all other appetite and passions. The more frequently they are indulged, the stronger they grow, until
they attain complete control and develop into destructive
habit

A free and confidential understanding in regard to these
matters between those who contemplate matrimony would go
far to prevent marital misery. A great deal of unhappiness
arises from the fact that mates in the matrimonial union often
labor under misapprehensions concerning the attitude of each
toward the sex relation, and are prevented by excessive
sensitiveness and delicacy from frankly discussing it. (For
further discussion of this subject, see page 390, Volume I.)

There is no problem of married life that needs more
thorough mutual consideration and understanding than this
one. Lack of it accounts for a great deal of "incompatibility,"
loss of love, revulsion, hatred, and the final tragedy in the
divorce court.

Among animals, no female allows intercourse after
conception. In this respect as in many others, man has sunk
below the natural standards of the animals. No greater crime
can be committed against the woman and the unborn life.

It is a sad commentary on our system of education,
scholastic as well as religious, that our young people are not
instructed before and after marriage in these all important
laws of Nature. To do this should be the province of the priest
who unites them in marriage, or of the family physician, if the
parents have failed in their duty.

It is well known (notwithstanding the denials of medical
skeptics) that the unborn infant may be "marked" by transitory
impressions, especially by strong emotions; that even
insignificant parental characteristics are reproduced in the
offspring. Is it any wonder, then, that the most powerful of
human emotions should leave its impress on the growing
brain and sex centers of the fetus, causing abnormal and
precocious sex consciousness?

All too often is sex perversion born and bred in bone and
flesh, before the child sees the light of day. The mother
cannot be blamed for this "slaughter of the innocents"; she has
not been instructed on the subject. Though she intuitively
senses the horror of it, she submits, in order to maintain her
hold upon the man—and many a life is thus cursed before it is
born. The fault lies primarily with those of the medical
profession who teach our young men that the free indulgence
of sexual passion is not only legitimate, but a necessity to
manly vigor.

This dictum of pseudo-science is almost universally
concurred in by spiritual guardians. No greater lie was ever
promulgated from the blackest abyss of Hades. If our
young men were taught that greater happiness is to be attained
by the exchange of tender affection than by the indulgence of
the coarser animal appetites, that the creative forces thus
preserved develop and strengthen their own finest capacities
of body, mind or soul, they would wisely and chivalrously protect mother and child, at the same time conserving their own physical and moral integrity.

In no other way is it possible to call forth the deepest gratitude and unfailing esteem of a true woman. Many a man whom we have thus advised has become a lifelong friend in consequence.

3. Limitation of Offspring. I believe that the unlimited production of offspring, encouraged in some quarters for swelling the ranks of religious bodies or for increasing tax paying and cannon-fodder material, is a misfortune, both to the family and to society. Limitation of offspring, in accordance with the means and circumstances of the parents, is not only justified but should be encouraged. In any case, the production of offspring entails great responsibility upon the parents and if they cannot properly comply with the needs and rights of their children, they fail in their responsibility and duty.

Any method, however, which interrupts intercourse or prevents conception in an artificial way, is absolutely to be condemned, because this has very harmful and positively destructive effects upon the physical, nervous and mental organism of those who thus try to cheat nature by the suppression of a natural process. In our professional work we frequently meet the victims of such pernicious practices. The ordinary contrivances for prevention make of intercourse something akin to masturbation. This is also true of intercourse without orgasm which is strongly advocated under various guises. The use of poisonous antiseptics and germ killers in warm water douches is not essential for prevention, and is highly injurious. These chemicals have a tendency to poison the sexual organs and to produce in time atrophy, many kinds of female disorders, and tumors. Undoubtedly the greater number of so called female troubles and malignant tumors in later life are caused by curetments, antiseptic douches and the use of poisonous drugs, for producing abortion. The only legitimate methods of birth control are abstinence or common cleanliness.

There is nothing more conducive to the physical, mental and spiritual health and development of a woman than childbearing and child rearing in harmony with Nature's laws, as outlined in these volumes. Under favorable conditions it is not a thing to be dreaded, but to be looked upon as the greatest of blessings and opportunities in the life of a woman. Natural philosophy and practice takes these problems of progeneration, childbearing and childrearing out of the domain of uncertainty and haphazard management with its dire consequences, and makes eugenics the most exact of all sciences and the sublimest and most enjoyable of all the arts.

4. Determination of Sex. Numerous theories have been advanced concerning this interesting subject. Many attempts have been made to wrest from Nature the secret of sex
determination and numerous more or less ingenious methods have been recommended for sex control.

I know of one method only which seems to have a rational basis and which has proved of practical value. Observations seem to prove that the right ovary liberates male ova only, while the left ovary discharges female ova. The two ovaries discharge ova only at alternate menstruations.

With this data at hand, it is possible to determine the sex of a child after one birth has taken place. Suppose the first child was a boy. By consulting our pregnancy table (page 377) we can determine when the last menstrual discharge took place. This menstruation liberated a male ovum; the next menstruation would liberate a female ovum, the next a male, etc.

Thus, using the last menstruation period before the last conception as a fixed point, it would be possible, figuring from period to period, to determine the sex nature of the ovum to be discharged at each following menstrual period. Account is taken of all regular periods during the time menstruation is suspended in pregnancy. Thus, conception may be timed in such a way as to impregnate at will a male or female ovum.

This solves in a simple, rational manner another of Nature's riddles, namely, the reason for the practically equal division of the sexes.

SECTION XXXIV

Prenatal Influence

There exists just as much diversity of opinion among scientists concerning the reality of prenatal influence as about race heredity, use heredity, disease heredity and many other mooted problems of science and philosophy, which we shall study in Vol. IV of this series. In the following I shall present and examine impartially the various theories and opinions concerning prenatal influence; then we shall be better prepared to draw our own conclusions.

1. Medical Science Denies Prenatal Influence. Medical men, as usual cocksure of the correctness of their theories and hypotheses based on the "latest discoveries", deny and ridicule the possibility of prenatal influence, and relegate it to the rubbish heap of popular superstitions. They base their judgment on the fact that no nerves pass from the body of the mother through the umbilical cord into the growing fetus in the placenta, which forms the soft protecting nest of the new life within the womb. They claim that since no direct nerve connection exists between the two, mental and emotional vibrations cannot be transmitted from the brain of the mother to the brain and nervous organism of the fetus.
Are there no other means of communication between the mind of the mother and the brain of the unborn!

In the volume dealing with Eugenics we shall learn how universal intelligence and creative will become individual intelligence and personal will.

Cosmic vibrations do not flow into the gray matter of the human brain over coarse physical nerve tracts. They come over the psychical wireless which connects the human soul with the world Soul, the individual intelligence with the universal or cosmic intelligence the human will with the divine will.

Since, as proved by modern brain and nerve anatomy, immaterial cosmic intelligence and "power to will" fashion the brain of the mother into physical material centers for the expression of human intellectual faculties, capacities and powers, why cannot these cosmic vibrations act in like manner over the psychic wireless through the soul and mind of the mother on the brain and nervous system of the fetal organism?*

These epoch making discoveries and revelations of modern brain anatomy are explained in Vol. IV of this Series, *Natural Eugenics—Man Building on the Physical, Mental and Moral Planes.*

Why should the wireless, which transmits impulses of intuitive intelligence from the great source of all intelligence and creative energy into the soul of the mother, cease to operate at that point, and fail to transmit its message to the brain and nervous system of the fetus which is most intimately related and connected with the organism of the mother?

What about the phenomena of hypnotism? Absolute control of the subject's mind, through the intelligence and will of the hypnotist does not depend upon the existence of an umbilical cord and physical nerve connection between the two. The hypnotist, by silent command, may call his subject from a distance, far beyond the reach of his voice.

People telepathically attuned may communicate in like manner, spontaneously, or by conscious intent. Why then should we doubt the possibility of vibratory correspondence between the mental and emotional conditions of the mother and the plastic nervous organism in process of development within her womb?

If a complexity of sound can impress itself permanently upon the wax cylinder of a phonograph, or what is still more marvelous, if the photographic rays of passing scenes can be fixed and retained in the picture film, why should it be impossible for the mental and emotional vibrations of the mother to impress and modulate the molecular and cellular constituents of the fetal brain and nervous organism?
I have compared this creative power of the mother mind to the process of electrotyping. As the particles of metal in suspension in the fluid adhere to the spoon that is to be coated with silver, so the atoms and molecules in the gray matter of the brain of the fetus group themselves in harmony with the thought forms and emotional vibrations of the mind and soul of the mother. While this mental and psychical electrotyping takes place automatically, the mother's brain and nerve molding power can be greatly strengthened and intensified by the conscious and voluntary operation of the psychical wireless that establishes vibratory oneness between her and the human entity in process of development within her own body.

Thus it is revealed how a brain prenatally refined, organized and fashioned may endow the nascent individuality with certain aptitudes and talents along established paths of cerebration. There surely will be less resistance along such lines of physical, mental and moral endeavor than along other lines not prenatally influenced and molded. Therefore I strongly advise mothers, pregnant with new life holding marvelous possibilities for good or evil, not to be influenced by the superficial reasoning of materialistic science, but to follow the sacred intuition and impulse of their own creative genius in this, the most holy function of their being. Every normally constituted mother is intuitively aware of this wonderful power, and is willing and anxious to exercise it when her consciousness has been aroused to the great possibilities and responsibilities which the divine privilege of motherhood confers upon her.

It is natural for us to admire a great artist who portrays the human form, true to life, on the painted canvas, or who fashions it from inanimate stone, metal or marble; how much more grand and godlike is the creative power of truly mated parents whose privilege it is to bring into the world, and to fashion according to their highest ideals, a human being endowed with life and intelligence, with the infinite possibilities of a new center of creative activity.

Yet many mothers, totally ignorant of their divine creative privileges and possibilities, victims of physically and morally degrading marriage relations, and often filled with secret aversion or open hatred for their marital companions, pass unwillingly through pregnancy and not infrequently seek to destroy the new life. When the unfortunate victim of such marital incompatibility, conceived in passion and developing under the worst possible influences of mental and emotional discord, comes to arouse the maternal instincts of affection and devotion, then fear, anxiety and worry, like a continual nightmare, haunt the unhappy mind of the mother and impress their discordant vibrations upon the sensitive films of infant consciousness.

Compare this condition of fear, apprehension and gloom in the mind and soul of an unhappy and unwilling mother, with the joyful and ecstatic state of mind of a mother conscious of
the creative power of her intelligent will, who, from the time of mating and procreation, with accurate prescience prepares the most favorable conditions, astrologically, prenatally and postnatally for the finest development of the physical, mental and moral characteristics of the future world citizen.

The loftiest exaltation of a creative genius working in dead clay and cold marble cannot approach the ecstasy of a mother who has acquired a knowledge of the great laws which make possible the development of a perfect human being, the embryo of a master, an angel, a being destined to be godlike in its faculties, capacities and powers!

In place of fear and anguish of soul, what joy to the mother who knows that it lies within her power to prevent disease and degeneracy in her offspring; that the development of the child depends solely upon her own intelligent effort! Nothing is left to accident. Child bearing becomes an exact science, the most beautiful and inspiring of all arts and professions. Under such conditions motherhood, instead of being the greatest of hazards and hardships, becomes a divine privilege and the highest achievement of human existence and endeavor. It falls short only of the creative work of the great Universal Intelligence whose instrument of creation is the mother.

2. An Example from History. Let us consider the oft-quoted example of Napoleon Bonaparte. His mother, Lutitia Bonaparte, while pregnant with the future military genius, accompanied her husband on a military expedition, sharing with him the hardships and excitement of camp life, and the marches and battles of a military campaign. If there be nothing in prenatal influence, is it not singular that Napoleon should have become one of the greatest military geniuses of all ages, while not one of his many brothers ever exhibited enough military ability to make an efficient corporal? What was it that favored or determined the birth of the great military prodigy under these circumstances? The ancestors of Napoleon's father were not professional soldiers, nor was the father especially interested in military matters before the conception of his gifted offspring.

The dominant influences, therefore, must have operated through the singular occupation and surroundings of the mother during this particular pregnancy.

Many similar striking examples have been cited in works on prenatal influence. I myself might add many convincing proofs from an extensive experience in medical practice; but time and space do not permit. Contributory evidence may be secured from many excellent works dealing with this vital problem in human life. I may be permitted to say that use heredity and prenatal influence are distinctly manifest in the physical and mental characteristics of our three children who were born at intervals of seven and five years. Each one of them clearly mirrors in his or her physical, mental and emotional peculiarities the predominant mental tendencies, occupation and surroundings of the parents during the
respective prenatal periods. Similar manifestations of prenatal influence may be observed in almost any family.

3. Birthmarks. Medical men of late deny also the possibility of "marking" the offspring by sudden fear or shock on the part of the mother during pregnancy. Incidents of this kind, however, are of such common occurrence that it is a waste of time to refute these flippant denials.

There are good reasons for believing that such marking is more likely to occur during the periods when the menstrual flow should take place, but is suspended.

It may be argued that to mention the possibility of marking to a pregnant woman will greatly increase the probability of electrotyping violent emotions upon her offspring; in other words, that the fear of the thing will help to materialize it. This may be true to a certain extent, but we must remember that sudden shock through fear or disgust may cause the mischief anyway, whether or not the expectant mother is aware of the possibility. Understanding a danger and being prepared for it seems the best protection. The pregnant woman should study carefully section XXX, dealing with mental and emotional causes of nervous diseases, and should learn to relax to any sudden surprise and thus neutralize unpleasant and fear arousing impressions. Self-control is the royal remedy and the key to mastership.

4. Physical Influence. Now that we have studied some of the more important hereditary mental and psychical prenatal and postnatal influences, let us see how the physical condition of the mother's organism influences the brain and nerve matter of the fetus in its last stages of development, and after birth.

Materialistic science teaches that brain matter exudes thoughts and feelings, as the liver excretes bile, or the stomach pepsin. Natural science proves that mind is superior to matter, that the new born ego, by the power of intelligent volition, must fashion in the gray matter of the brain the molecular groupings or centers for the expression of intellectual and emotional activities, such as language, music, numbers, scientific and philosophic speculation.

This means that active cerebration and brain molding do not begin until after birth. But it stands to reason that the work of the nascent intelligence may be greatly facilitated or impeded by the physical condition of the brain. It is reasonable to assume that intellectual and emotional vibrations will more easily shape the gray matter of the brain into new configurations when it has been prenatally refined, organized and developed along certain lines of cerebration by use heredity and by constructive prenatal influences.

There exists a remarkable similarity between the brain molding and memory building activities of the intelligent ego and the making of phonographic records and moving picture
Lifelike impressions of sounds and passing scenes can be made upon the phonographic and photographic mediums only when wax and film are in a highly refined and plastic condition. When impure of substance and coarse of texture they, are not sensitive and plastic enough to register and retain the subtle and highly complex vibrations of sounds and passing scenes. In order to receive and register a great variety and complexity of sounds, the wax on the phonograph cylinder must possess a certain degree of refinement, softness and plasticity. If it is too hard and coarse it registers the loud and coarse sounds only. Such a record cylinder, exposed to a beautiful symphony executed by a great orchestra, would register and reproduce only the shrill cries of the trumpet, the rattle of the snare drum and the booming of the big horns and bass drums. The softer sounds of string, wood and wind instruments and finer shadings of tone and rhythm would be lost. With increasing refinement and plasticity, more subtle and delicate sound vibrations will be retained and reproduced.

In like manner the sensitive gray matter of the cortex of the brain must be in a pure and plastic condition in order to receive and register the impressions and impulses coming through the sensory organs, the psychic intuition and the intellectual and emotional activities of the mind. Anything in the way of physical impurity or foreign matter that tends to clog the brain, or to feed it with waste and morbid materials, or with corroding poisons, will lessen the atomic and molecular motility of brain and nerve matter, and will interfere with, or impede, the groupings and subtle transformations involved in the fashioning of brain centers through mental and emotional influences.

If the nutrient blood which feeds the brain substance of the fetus be saturated with CO$_2$, the benumbing, paralyzing carbon-dioxide, with clogging uric acid or the destructive acids of phosphorus and sulfur, the gray matter cannot, respond to the subtle and complex impressions and impulses from without and within.

The purity or impurity of the plastic matrix of the cortex depends upon the materials absorbed from food and drink. If these are so constituted as to create in the system excessive amounts of clogging and corroding substances, then these food and drink poisons will have a benumbing and deteriorating effect upon the sensitive gray matter of the brain, as well as upon the coarser tissues in the joints, muscles and vital organs. There is a rheumatism of the mind as well as of the joints.

A brain asphyxiated and clogged with pathogenic materials cannot be alert and active; it is too dull and lazy to think; it would much rather sleep than work; it is incapable of doing its best when its tiny blood and lymph vessels are obstructed with waste and morbid deposits which prevent the oxygenation and drainage of its delicately organized cellular tissues.
This, of course, is true postnatally as well as prenatally. A brain originally capable of the highest and finest achievements of the human mind may become utterly worthless, and may degenerate into idiocy through food, drink and drug poisoning.

Medical men tell mothers they need not worry over prenatal feeding, because the placenta, the vascular bag which forms the nest of the new life, acts as a filter which purifies the blood before it reaches the fetus. Common sense and every day experience tell another story. Even the best in the blood of many mothers is bad enough to serve as food for the new life.

The placenta does not filter out of the blood of the mother all food, disease and drug poisons. This is proved by the wretched condition of many infants, suffering from malnutrition, anemia and rachitis, after delivery. If the vital fluids of the mother are deficient in the mineral elements, or in other important nutritive substances, how can they deliver them to the fetus?

Occurrences like the following, quite common in our institutional practice, prove positively that the placenta is not a perfect filter for systemic poisons and for disease taints circulating in the blood of the mother.

One of the most pitiable cases of eczema in a little child less than one year old we traced to the fact that the mother, during her first year of marriage, had traveled with her husband through Eastern European and Asiatic countries, and during her pregnancy had been vaccinated five times while passing through localities where smallpox was prevalent. Both she and her husband had always enjoyed perfect health. The family record was excellent as far as traceable; still the body of the infant soon after birth, was covered with open bleeding sores, presenting a revolting sight. We could find no explanation for this strange phenomenon other than the many vaccinations during pregnancy. These had contaminated the blood of the mother, and through her the body of the fetus, with a filthy scrofulous taint.

The baby suffered terribly. For many months it slept but little, because of the excruciating pains. The eczematous eruptions were of a very stubborn nature; they broke forth again and again. Finally, however, after eighteen months of natural treatment, we succeeded in purifying the little body of the horrible infection. The child is now a little over three years old, in perfect health, and during the last twelve months has shown no signs of the morbid taint.

Under another section I shall describe the influence of food upon character and sex life.

To recapitulate: Purity, plasticity and motility of the highly refined and sensitive materials which make up the gray matter of the brain depend upon pure food, plenty of fresh air and exercise, and upon all other natural methods of living.
SECTION XXXV
Conception and Pregnancy

1. Conception takes place whenever the male spermatozoon joins the female ovum (egg) within the woman's womb. Normally the female organism liberates from its ovaries but one ovum each month, usually during menstruation, while the male discharges millions of spermatozoa at each orgasm.

Conception does not always follow copulation. The ovum remains in the womb and is capable of impregnation for about five days after menstruation. The spermatozoon on entering the womb may meet an ovum which has been discharged at a previous menstruation, or it may remain alive in the womb for a number of days and finally come in contact with a newly discharged ovum at the following menstruation.

The spermatozoon retains its ability to impregnate the ovum for from ten to fifteen days after its discharge into the womb. When the male and female germs merge into one another, conception or impregnation takes place. As soon as this has happened, the impregnated ovum becomes attached to the inner lining or mucous membrane of the womb and begins its new life as an embryo. The period comprising the time from the impregnation of the ovum until the beginning of labor or childbirth is called pregnancy.

The table of pregnancy on page 377 indicates the probable date of normal termination of a pregnancy, calculated from the last menstruation.

2. Exercise During Pregnancy. Unfortunately a great many expectant mothers labor under the idea that they must rest and be relieved from work and exercise. This of course is a great mistake. Light housework is good exercise. There is nothing more harmful during pregnancy than nursing "that tired feeling" by lounging idly about the house and coddling one's real or imaginary aches and troubles.

Of great benefit to the pregnant woman are all outdoor sports such as tennis, golf and other games which require vigorous exercise without straining or overworking the body. The great benefit of walking and other outdoor exercises, aside from their general invigorating effects, lies in the strengthening of the abdominal muscles and ligaments, which at delivery will greatly facilitate expulsion of the fetus.

The walk should be brisk and rhythmical, body erect, head thrown back, chest forward; the breathing at the same time should be deep and regular. These walks should be continued as long as time and endurance permit. Nothing, of course,
must be pushed to the point of exhaustion. One good long walk every day is necessary; two are better.

We all understand the necessity for a plentiful supply of oxygen under ordinary conditions, and especially in time of illness. During pregnancy the demand for oxygen, as well as for mineral salts, is doubled or trebled on account of the needs of the rapidly developing organism in the womb of the mother.

These extra demands for oxygen and ozone must be supplied by systematic deep breathing, cold bathing, outdoor walks, etc. If circumstances do not permit the taking of outdoor exercise, deep breathing should be practiced as often as feasible, at the open window.

Next in importance among gymnastic exercises is the internal massage described under section XXI, No.16.

Those exercises are especially valuable which bring into play the abdominal muscles and the muscles and ligaments of the genital organs.

3. Clothing. Clothing and the manner of wearing it profoundly influences the normal or abnormal development of the fetus, the health of the mother, labor and delivery.

At no time should the waistline be constricted by a corset or even by the ordinary skirt band. All clothing should be as loose and light as possible—one-piece under and outer garments, with the weight suspended from the shoulders, are best. If skirts are worn they should be fastened to skeleton waists of some thin cotton material. The close, heavy texture of the material from which the corset or so called "reform waist" is made is injurious because it interferes with skin elimination.

Even the slightest constriction of the waist line interferes with the free circulation and the normal blood supply to the abdominal organs, which is of especial importance in pregnancy; it also hinders the free expansion and movement of the uterus during the various stages of pregnancy.

Within the waistline are located a dozen or more important vital organs of the body. Any sort of constriction compresses these organs and pushes them out of their normal position. While this is extremely injurious to the body of a woman under ordinary conditions, it is doubly so to the pregnant mother and to the rapidly growing fetus. Undoubtedly many deformities and monstrosities are produced by unnatural constriction of the blood vessels and vital organs in the abdomen and pelvis of the pregnant woman.

If due attention is paid to the foregoing influences, labor and delivery will be brief and easy. This we have proved in hundreds of cases which have come under our management. The reason why women of civilized countries spend many
hours and sometimes days in dreadful agony of childbirth while those of primitive or savage races, as we call them, produce their young easily and painlessly as the animals do, is that primitive women live more simple and natural lives, while "civilized" mothers violate practically every law of Nature in their daily habits of living.

Civilization unfortunately stands in many respects for that which is artificial, unnatural and therefore productive of disease and suffering in all domains of life, not only as regards physical health, but social and political health as well.

SECTION XXXVI

Danger Signs During Pregnancy

1. Dropsical Swelling. Swelling of the limbs and distention of the veins of the legs during pregnancy may be caused by a tendency towards varicosity, intensified by obstruction of the circulation due to the enlarged uterus. Such a condition requires, aside from the natural regimen, careful and competent treatment.

Swelling of the limbs or other parts of the body may also be caused by incipient or advanced Bright's disease. The urine should be examined from time to time, especially if there is a swelling of the feet and ankles, or if there are dropsical symptoms in other parts of the body.

Such dangerous conditions are usually brought about through the excessive intake of starchy and protein foods which overwork the liver and kidneys and cause pathogenic dogging of the capillary circulation. This may result in uremia attended by violent and sometimes fatal Convulsions.

2. Uremia is the result of retention in the system of waste materials and poisons that should be eliminated through the kidneys and skin. Medical treatment for such conditions, aside from the administration of stimulating drags, consists in hot bathing with the idea of opening the pores of the skin.

We understand that all hot water treatment gives only temporary relief and is followed by greater enervation and inactivity of the skin. The best water treatment for systemic poisoning of any kind consists in the application of wet packs followed by cold ablutions as described in section XV.

The addition to the packs, dry friction rubs, air bath, good massage and neurotherapy treatment will aid in restoring the normal activity of skin, bowels and kidneys.

Whenever the urine contains sugar or albumen, fasting, alternating with raw food diet, is indicated. Suitable regimens are outlined in sections X, XI.
The giving of heavy food to the mother with the idea of increasing the flow of milk is all-wrong. We have found in all cases that the diet outlined in section X will produce a more copious flow of rich milk than lie "nourishing" meat diet. The best remedy for a scanty flow of milk is slow and thorough mastication of a few spoonfuls of raw crushed wheat every day.

3. **Morning Sickness.** One of the common disorders experienced during pregnancy is that known as Morning Sickness. One suffering from this ailment, though following a natural diet, should sip a cup of hot postum while remaining in bed. If this does not have the desired effect and if the patient has not been accustomed to drinking coffee, half a cup of black coffee with a few drops of lemon juice will quiet the irritated nerves. It is necessary after taking the hot drink to remain in bed for at least thirty minutes. It is understood that this is only an emergency measure. If continued, it will lose its good effect and work injury.

**SECTION XXXVII**

**Labor and Delivery**

At about forty weeks, exactly nine solar months, from the period of conception the fetus reaches full maturity, and labor begins. Labor is divided into three stages. During the first stage the neck of the womb becomes slowly and gradually distended and the orifice of the womb opens widely. When this has taken place, the fetal membranes burst and the amniotic liquid surrounding the fetus escapes.

During the second stage the fetus emerges from the womb.

After expulsion of the fetus, the placenta is expelled from the uterine cavity. This constitutes the third stage of labor.

The first stage usually begins with more or less radiating pains in the abdomen, accompanied by dull pain in the small of the back and a drawing pain in the limbs. Sometimes women with the first baby feel these pains weeks in advance of the actual commencement of labor. At first they occur at long intervals and are of short duration, but gradually become more prolonged and more frequent. The pains are due to a cramp-like contraction of the muscular apparatus of the uterus forcing its contents downward.

Under this pressure from above, the neck and mouth of the uterus distend to their limits, and the walls become thinner and thinner. First the inner, then the outer orifice of the neck of the womb opens and the fetal membranes protrude and finally rupture, allowing the amniotic fluid to escape. Shortly after this the part of the fetus nearest the orifice, normally the
head, makes its appearance. At the present time the average duration of the first stage of labor is six hours, but it may last twenty-four hours or longer, depending upon the plasticity and elasticity of the bony structures of mother and infant, the rigidity of the cervix, and the vigor or lack of vigor of the muscular apparatus of the uterus.

While the foregoing is true of the average delivery under ordinary ways of living, we find that after the enforcement of a natural regimen of living during and, better still, before pregnancy, the entire period of labor and delivery does not cover more than half an hour, or at the utmost from one to two hours. Even the disadvantages of slight build and smallness of pelvis can be overcome by the natural regimen outlined in section X. When our youngest child was born, the mother gave the first sign of pain at about midnight. I rose from bed instantly, but had not time to finish clothing when the membranese broke. Within twenty minutes after the commencement of labor the infant was resting in my hands.

The wife of a prominent lawyer in a western city had experienced three difficult deliveries. Each time surgical instruments had to be used and she had suffered untold agonies lasting from 24 to 36 hours. When she became pregnant the fourth time the most prominent physicians in her home city assured husband and wife that it was not safe for her to go through another delivery, that the womb was in worse condition than ever before therefore they recommended surgical removal. For conscientious reasons, however, the husband and wife did not follow the advice of the doctors, but decided to try natural methods of treatment.

The lady placed herself under our care during the fifth month of pregnancy. From that time on she followed strictly the natural regimen of living and received daily the usual hydropathic and manipulative treatments. This was continued until a few weeks before delivery. In this case the baby was born within an hour from the first contraction, and the mother of the patient, who was in an adjoining room, had not heard a sound. Many similar experiences refute the idea that it is unsafe and injurious for pregnant women to undergo the ordinary methods of natural treatment, such as hydropathic sprays, sitz baths, massage, Swedish movement and other forms of manipulation.

1. Preparation for Delivery. The diet during the last week before the beginning of labor should be very light, consisting mostly of fruits and vegetables. From the commencement of labor no food at all should be given, until at least twenty-four hours after delivery; a three-day fast is better.

In addition to a competent physician, a nurse or midwife should be engaged. If a good neurotherapist, who has had sufficient experience in obstetrical work, can be procured, he should be preferred, because he can assist delivery and make it much easier by manipulative treatment.
The nurse will make the necessary preparations and provide the various supplies needed in labor. With the first sign of approaching labor, the physician in charge should be summoned. A rectal enema of one pint or more of warm salt water (See. XVIII, No.4) should be administered. The woman should be given a vigorous cold rub and her genitals thoroughly cleansed. She may then remain on her feet and walk about, comfortably dressed, until actual labor commences.

2. No Anesthetics. The attending physician should not be impatient to hasten delivery with drugs or instruments. The use of anesthetics should be avoided insofar as this is possible. They should be employed only when absolutely necessary—that is, when excessive pain must be allayed or when surgical delivery is unavoidable.

3. Breaking of Water Bag. When the bag of water is about ready to break, the patient is placed in bed. Premature discharge of the amniotic fluid must be guarded against. An escape of the liquid at an early stage means difficult and prolonged labor, commonly known as "dry labor". Usually the membranes burst when the orifice is fully dilated. A large sponge is held in readiness to catch the out-flowing liquid.

3 a. Umbilical Cord. When the infant has been delivered, the umbilical cord should not be severed at once. Plenty of time should be allowed for the blood to transfuse itself from the body of the mother to that of the child. This is important. If the connection is severed too soon, the child begins life in an anemic condition.

The newborn baby usually greets the world with a lusty cry. It should be placed on its right side with its face turned away from the mother, care being taken that the cord is not stretched tight. As soon as the cord stops pulsating, plenty of time being allowed for blood transfusion, it is tied about two inches away from the baby's abdomen and cut a little above the ligature. The baby is now wrapped in a warm blanket and put in its crib.

4. After Delivery. Immediately after the baby is born, the nurse or attending physician gently compresses the abdomen and womb of the mother, kneading and rubbing it occasionally in order to secure complete contraction and thus prevent hemorrhage. After delivery the mother enjoys a period of rest and recuperation which usually lasts for about half an hour.

5. Afterbirth. Meanwhile the placenta becomes detached, and when the pains set in again a few contractions usually suffice to expel it with all the membranes.

The attending physician must make sure that none of it is left in the body, since this might result in putrefaction of the remains and blood poisoning. The woman's genitals should be washed with clean sterilized water.
The exhausted woman should now enjoy a deep, wholesome sleep and awaken from it in a few hours refreshed and strengthened.

In the foregoing I have not gone into the details of obstetrics and of technical management because this must be left to a competent obstetrician. I have called attention only to those points which are of special importance from the viewpoint of Natural Therapeutics and to the differences in treatment between the conventional and natural methods.

6. The Lying-In Period. The lying-in period varies from five to twelve days, according to the constitution of the mother and the care that she has taken during pregnancy. The greatest danger of the lying-in period is puerperal sepsis or blood poisoning. This condition is the result of infection occurring during labor, or it may result from the retention of parts of the placenta.

The only way to prevent this is by observing the most scrupulous cleanliness during the entire process of childbirth and during the lying-in period. When blood poisoning has developed it must be treated the same as all other acute inflammatory diseases (see section IX).

7. Care of the Newborn. The child should begin to breathe immediately after the cord is cut. If it fails to do this, the physician should lift the baby by its feet to facilitate the escape of mucous from the trachea and throat. If necessary the mucous must be removed from the throat by the insertion of the little finger, or by means of a tiny stick covered with gauze.

Breathing may be accelerated effectively by a few sharp taps on shoulders and buttocks. If this fails to bring the desired result, artificial respiration must be resorted to at once. The attendant grasps the child by its shoulders, its head resting between his palms and the two index fingers being hooked under the child's armpits. It is now swung between the physician's legs and lifted high above his head so as to be turned upside down. This is repeated from fifteen to twenty times, after which it is placed in a basin containing a few inches of warm water. Its body should then be rubbed briskly with cold water.

Father Kneipp used to take the newborn babe by the nape of the neck and the feet and submerge it quickly in cold water. This, a few times repeated, is probably the quickest way of resuscitating an asphyxiated baby.

In order to soften the cheesy deposit which frequently covers the body of the newborn, it is well to rub the skin with warm olive oil. After the greasy covering has sufficiently softened it may be removed with bits of gauze. This is followed by a cleansing bath with warm water and castile soap.
After the warm cleansing bath, the little body should be quickly rubbed down with cold water, wrapped in a soft, warm blanket and laid away to sleep until it wakens of its own accord. A normal baby should sleep for about twelve hours, and must not be disturbed to force food on it before it is ready to take it.

8. Bathing. From the first day, the baby must have a morning and evening bath. This consists, as before described, in a quick, cleansing bath of warm water and castile soap, followed immediately by a brisk cold rub. In the course of a few weeks the baby can be placed, for the cleansing bath, in a small bathtub containing a few inches of warm water. Immediately after the cleansing bath the warm water is replaced by cold water. This is taken up in the hollow of the hand and briskly applied to the little body. In this fashion the child, within a few months time, will enjoy its cold rub just as much as an adult. I have seen several such nature cure babies, but a few months old, object most vigorously to a warm bath. The cold rub is the best preventive of chilling; but care must be taken that the temperature of the room where the bath is given is not below 70 deg.

The olive oil bath or rub, often recommended for premature babies or infants suffering from malnutrition, is very injurious, because it occludes the pores of the skin and prevents the elimination of poisonous gases and other morbid materials from the body. The skin is not an organ of digestion. Olive oil, like all other foods, must enter the body through the alimentary canal where, under the action of digestive ferments, it is broken down into its component elements which are then assimilated through the intestinal membranes. Oil absorbed through the skin is not digested, and it circulates in the body as foreign matter which in this state cannot be assimilated and utilized in the system.

9. Powdering after the bath is fully as injurious as the rubbing with oils or massage creams. Powders and creams tend to clog the pores, and most of them contain poisonous antiseptics which lower the vitality of the skin and prevent or suppress elimination in the form of skin eruptions, eczemas, etc. For chafing use nothing but cold water. In case the chafing should become unusually severe and painful, through neglect by the caretaker, a soothing and healing lotion composed of one part lemon juice to two parts olive oil, may be applied a few times, until the irritation is under control.

10. Air Baths. Next to cold water, there is nothing that will invigorate baby’s skin and nervous system as will the air and sun bath. If the season will not allow the outdoor air bath, the baby should be allowed to lie nude several times a day, for thirty minutes or more, in a warm, well ventilated and sunny room.

11. Constipation. Glycerin and suppositories should never be used; neither laxatives nor cathartics. Oat extract and cooling sitz baths will produce natural movements.
Diarrhea is a form of morbid elimination, and must never be suppressed by drugs. If it is habitual, bailey or wheat extract prepared in the same manner as oat extract, is a good remedy. If the diarrhea is persistent and of a violent nature, no food at all must be given, except water with dilute acid fruit juices, until the purging ceases. Even then plenty of time must be allowed for the rebuilding of the sloughed intestinal membranes.

Bandages. Until the umbilical cord dries up and falls off, it is necessary to cover the navel with a gauze compress dipped in olive oil. This is held in place by an abdominal bandage made of soft cotton material. These strips should not be hemmed, merely torn or cut. They should be drawn just snugly enough to hold the compress in place, but not tightly enough to interfere with circulation. The navel must be cleansed and the compress renewed twice each day. After the umbilical cord has dropped off we no longer apply the abdominal bandage. This is contrary to common usage, but is the best practice. The abdominal bandage overheats the body and interferes with the free movement of the diaphragm and the circulation of the blood.

Clothing. The clothing of the infant should be loose and light and as simple as possible. Freedom of movement is very important; binding or pressure upon any part cannot help but interfere with the circulation, and otherwise produce injurious results. The clothes should be short, in order to allow the feet and legs free play. Light weight, porous cotton materials are best for both under and outer garments. A lightweight wool petticoat may be worn when absolutely necessary to provide sufficient protection for the baby. Cotton hose and bootees may be used, but under no circumstances should such articles be of wool, because it prevents free elimination from the skin. The baby's head should not be covered out of doors, except in severe weather. At no time should a veil be placed over the face, as it will cause the infant to reabsorb the poisonous exhalations from its own lungs. All clothing should be changed each day. No garment should be starched—such a practice is not only useless but harmful.

Diapers must be provided in sufficient number to allow thorough cleansing and drying. The wet diapers should be scalded in hot water and very thoroughly rinsed in several waters afterwards. They should then be dried in the open air and sunshine. Soiled diapers must be well washed and boiled. Washing powders, soda, ammonia and other chemicals should never be used. They have an extremely irritating effect upon the delicate skin of a baby. In order to save labor and to facilitate the cleansing of the diapers, small squares of clean old linen or muslin rags, or pieces of absorbent gauze, may be placed inside. These inserts will absorb all or most of the bowel movement and may then be burned. If the skin is irritated or chafed, the parts should be sponged off with clean cold water at each change, paying special attention to cleansing of the genitals. Oils or powders must not be used to soothe the sore places, because they clog the pores and
16. **A wet nurse** is to be preferred to artificial feeding. She should be thoroughly healthy, not over thirty years of age, of equitable temper, not excitable or nervous and her diet should be that prescribed for the mother.

17. **Care of the Nipples.** They should be thoroughly cleansed before and after nursing; not with carbolic acid, but with water and dilute lemon juice. The lemon juice tends also to harden the nipples. Treatment of the nipples may begin before the birth of the child.

18. **Care of the Eyes.** The baby's eyes, whether awake or asleep, should always be shielded from strong light, either sun or artificial, and from dust and wind. The eyes should be washed with cold water after every cleansing bath. If they show any tendency to weakness or disease, slight vibratory massage over the closed eyelids should be given after the cold eye bath.

19. **Care of the Mouth.** A healthy baby's mouth needs no cleaning before the arrival of teeth. As a matter of fact, the teeth of a perfectly healthy adult would not need cleaning any more than do those of an animal living in the freedom of nature. The saliva is a sterilizing fluid, under normal living, intended by Nature to keep the mouth clean and healthy. Cleansing of the mouth of an infant with the finger or with a cloth may injure its delicate membranes. If the mouth must be washed, in case of disease, a swab made by twisting a piece of sterilized absorbent cotton on the end of a smooth stick should be used. The swab should be dipped in warm boiled water, and the interior of the mouth washed thoroughly, the cotton then being burned.

20. **Care of the Ears.** The external ear should be cleansed with a soft rag or swab as before described. Never use a hard instrument inside the ear.

21. **Care of the Nose.** A baby's nose should be cleansed as a part of the daily toilet, in the same way as the ears. A swab may be made by twisting a, piece of gauze to a cone. As soon as the child becomes old enough, it should be taught to sniff up cold water through the nostrils and the nasal passages. This is the best way to keep the nasal membranes in a clean, healthy condition.

22. **Care of the Genital Organs.** The genital organs of both sexes must be kept scrupulously clean with as little handling as possible. The foreskin of the penis of the male baby should be drawn back at bathing time and the organ thoroughly cleansed, always finishing with cold water.

23. **Phimosis.** The treatment of phimosis is fully described under Sec. XXVIII, No.1.

24. **How to Lift the Baby.** The best way to lift a young
baby is to slip the left hand under the back beneath the shoulder, spreading out the fingers in such a way as to support the neck and head. Then lift the feet and legs with the right hand. **Never lift an infant without first supporting the spine.**

When a baby has grown strong enough to hold up its head and has gained considerable strength in the muscles of the back and neck, he may be lifted by grasping him with outspread fingers under the armpits; the body must be held firmly so that the entire strain does not come on the shoulders. A baby should never be lifted by the arms. This may dislocate the shoulder joints.

**SECTION XXXVIII**

**Prenatal Feeding**

1. **Effects of Diet During Pregnancy.** The problem of infant nutrition begins before birth. Prenatal feeding determines the physical start in life. On it depends not only the condition of the mother's health during pregnancy, but also the size and weight of the fetus, pliability of the bony structures, ease or difficulty of delivery, and the quality of the mother's milk.

   The fleshier and heavier the newborn infant, the prouder and happier are the parents and the doctor. Yet, excessive size and weight of the child constitute the most prominent cause of difficult and painful childbirth and frequent necessity for instrumental delivery.

   The biblical saying, "In sorrow thou shalt bring forth children"; has led many to believe that woman's dreadful suffering is a necessity, God ordained; but is not man's ignorance, rather than the cruelty of an avenging God, to blame?

   This latter view is confirmed by the fact that other mammalia literally cast their young, without pain or difficulty; and the labor pains of primitive mothers are insignificant, their delivery presenting little more difficulty than that of the lower animals. A squaw on the Western Plains stops a few hours by the wayside to deliver her papoose and then resumes her journey as though nothing had happened.

   Women among the European peasantry, who wear no corsets, live on black bread and vegetables, and have plenty of exercise in the fields and in the home to the last day of pregnancy, have their babies without help of midwife or physician and resume their usual routine of work within a few days after delivery.

   Thousands of mothers who have adopted natural ways of
living have learned to dispense with anesthetics and the surgeon's instruments; they now bring forth their offspring without excessive pain.

2. Results of Faulty Diet. It is significant that the offspring of the lower animals, at birth, consist of little more than skin and bones, while the newborn human is often abnormally large and fat. This is especially true of babies born of weak and anemic mothers. As before stated, excessive size and weight of the infant is not a matter for congratulation, but is a pathological condition. It indicates fatty degeneration of the fetus, due to the anemic watery condition of the blood of the mother, and the cause of this hydremia of mother and child lies in the faulty dietetic habits of the former.

The ordinary diet of American women consists almost entirely of meat, fish, fowl, potatoes, white bread, pastry, coffee, tea and refined white sugar. The few vegetable, which enter into the daily dietary are first deprived of their all important organic salts by faulty cooking; fruits are looked upon as luxuries and frequently are regarded as harmful.

The anemic, watery condition of the blood of mother and child is not due to a lack of starchy, protein and fatty materials in food and blood, but to a deficiency of organic mineral elements. Neither is the anemic condition, as the regular school of medicine assumes, caused by lack of iron. Any ordinary food mixture, as well as the blood and milk of anemic mothers, usually contains a sufficient amount of iron. The actual cause of the anemia is a deficiency of other mineral elements.

As I have explained in Volume III of this Series, carbonic acid poisoning and the resulting sluggishness of the surface circulation, coldness of the extremities and congestion of the inner organs is not caused so much by a lack of the oxygen-carrying iron as by a deficiency of the carbonic acid neutralizing and eliminating sodium and magnesium.

If the blood is deficient in lime, phosphates, silicon and fluorine, rachitic conditions, softening of the bones, deformed spines and legs, and decay of the teeth, are inevitable results.

It is an easy matter to supply the daily needs of the organism for proteids, starches, fats and sugars; the difficulty lies in supplying a sufficient amount of the organic mineral elements.

The deficiency of sodium in human blood, Dr. Lahmann proved in the following table of comparative blood analyses.

<table>
<thead>
<tr>
<th></th>
<th>Per Cent of Sodium</th>

<tr>
<td>Blood of hogs</td>
<td>5.33 to 7.62</td>
</tr>
</tbody>
</table>
The percentages of lime and of other positive mineral elements in the human blood are also much lower than in the blood of cows, oxen and sheep.

While the blood of cattle and sheep raised on pasture is very uniform in composition, hardly any two samples of human blood are alike. It is for this reason that Dr. Lahmann adopted cow's milk instead of human milk as the standard elementary food combination.

In the following table, he compares the percentages of minerals in the ash of cow's milk with the percentages of mineral elements in the ash of various other food materials.

A daily dietary consisting largely of meats, eggs, white bread, potatoes, peas and beans, though excessively rich in proteids, fats and starches, will, on account of its deficiency in sodium, lime and magnesium, inevitably result in carbonic acid poisoning, anemia, rachitis, premature decay of the teeth and a multitude of other acute and chronic ailments.

If, however, the daily dietary contains a liberal amount of green vegetables and fruits, a normal food mixture resembling that of cow's milk can easily be obtained. It must be remembered that fruits and vegetables are not only rich in the most important mineral salts, but that they are relatively poor in proteids and carbohydrates.

For this reason fruits and vegetables facilitate the establishment of an equilibrium between proteids and carbohydrates on the one hand and organic mineral salts on the other.

3. **Excessive Fat Formation.** We can now understand why the ordinary faulty diet of pregnant mothers causes anemia, softening of the bones, sluggish circulation, carbonic acid poisoning and fatty degeneration in mother and offspring.

Lack of sodium causes excessive accumulation of carbonic acid, and oxygen starvation. This results in defective...
oxidation of food and waste materials; in other words, in fat formation.

Defective draft prevents the complete consumption of coal, and chokes the furnace with the products of imperfect combustion. Similarly, lack of oxygen in the tissues (due to carbonic acid poisoning) causes an incomplete combustion of food materials and waste products, resulting in fat formation and in the generation of poisonous byproducts.

Lack of sodium also prevents the neutralization and elimination of uric and other acids and ptomaines (pathogenic matter) which accumulate in the tissues, block the circulation and assist in the smothering of the vital processes.

In order to eliminate these pathogenic materials, there arises an abnormal craving for water—"the anemic thirst"—which is closely related to the thirst of fever patients and of diabetics. Excessive water drinking is encouraged by the popular "flushing" fad.

To make things worse, the anemic, for reasons before stated, usually suffers from weak heart action and sluggish circulation. This means defective elimination of water through the skin and kidneys, resulting in a watery (dropsical) condition of the tissues and fatty degeneration.

Not all anemic, carbonic-acid-poisoned mothers, however, develop a tendency to obesity. On the contrary, under certain constitutional conditions, they may become exceedingly lean, like the anemic, carbonic-acid-poisoned consumptive. Briefly stated, sluggish heart action and weak kidneys favor retention of carbonic acid and water in the tissues and thus make for fatty degeneration. Good circulation and normal activity of the kidneys may keep the system free from excess of water and carbonic acid, but excessive proteids in the diet may result in sulfuric and phosphoric acid poisoning. These destructive acids break down the tissues, rob them of their mineral constituents, and thus cause excessive loss of flesh and fat.

In both types of dysemia the blood of the pregnant mother is overloaded with poisonous gases, waste matter and the debris of broken-down tissues. The oxygen supply to the fetus is therefore very much impeded and we find that both fleshy and lean mothers produce babies of abnormal size and weight, ranging from eight to twelve pounds, while the normal weight of the newborn should not be more than six pounds.

4. Advantages of Natural Regimen. We know of many instances where mothers, after having given birth to heavy, fleshy babies, in subsequent births have reduced the weight of the new born to normal, and the pain of delivery to a minimum, by the adoption of a natural diet, plenty of exercise in the fresh air and systematic deep breathing.
The effects of a natural regimen are manifested in various other ways. The bony and muscular structures of mother and child are much more pliable and elastic, making parturition and delivery much easier. Pure blood, normal nutrition and abdominal exercises, walking and special gymnastics, greatly strengthen the abdominal and uterine muscles, thus facilitating expulsion of the fetus.

The morning cold rub, systematic deep breathing and general exercises, every day outdoor walks and right mental and emotional attitude are all of paramount importance in the regimen of pregnancy.

The Regimen for Wholesome Living, section I, is admirably adapted for all the needs of the pregnant mother.

SECTION XXXIX

Postnatal Feeding

Thanks to the educational influence of nature cure propaganda, a decided change for the better in baby feeding has taken place during the past ten years. Up to that time the "top cream mixture" was universally recommended by allopathic physicians and given to babies by trained nurses.

While in the meantime many physicians and nurses have adopted more natural methods, the "top cream mixture" is still too common and must be entirely abolished in order to safeguard the health of our little ones.

In the February, 1909, issue of the Nature Cure Magazine, I commented upon this subject as follows:

1. Bottle-fed Babies. Our food analyses disclose the interesting fact that the elementary composition of the ash of the milk of an animal is about the same as the composition of the ash of its body.

They also show that good cow's milk when normal comes closer to the requirements of the infant body than does inferior human milk.

Our tables of food analyses show that chemically the composition of cow's milk and of human milk is very much the same. Human milk contains a little less proteid and a little more sugar than cow's milk, and the latter is much richer in organic salts than the former. There is much more of the all-important sodium in cow's milk than in human milk and about twice as much calcium (lime) and iron (table p.100). This explains why rachitis is so common among babies, while never found among calves.

As we have learned, the elimination of poisonous acids
from the body depends on sodium. The building of the bony structures depends on lime; the oxygenation of the blood, on iron.

Many years of practical experience in the care of babies has convinced me that milk fresh from a healthy cow is greatly to be preferred, as nourishment for infants, to the impoverished milk of scrofulous mothers.* In this connection it is significant that one-half of all "civilized" mothers, thanks to unnatural food and drink, vaccination and poisonous drugs, are incapacitated for nursing their offspring.

* This may not be true in the future if our milk cows continue to be regularly subjected to tuberculin tests.

To one who has studied the comparative analyses of cow's milk and human milk, it is incomprehensible why the former, when given to infants, should be diluted and spoiled by large quantities of water, salt, soda and inorganic mineral lime (in the form of lime water).

This procedure, however, is still frequently recommended by physicians of the regular school. Undoubtedly, the great frequency of anemic and rachitic diseases, the darkening of the iris, appearance of scurf rim, and the signs of catarrhal conditions in stomach and bowels are caused by such unnatural feeding.

The following extracts are taken from an article entitled "Bottle-fed Babies", in the Ladies’ Home Journal. It was written by Dr. Emelyn Lincoln Coolidge, of the Babies' hospital, New York. Thousands of mothers, on account of the high standing and excellent reputation of this family journal, undoubtedly have followed, without question or misgiving, the advice presented.

The formulas given below are for the average healthy baby, and are called "cream" or "top milk" mixtures.

"Food for the first month. With a spoon, or a tiny dipper which comes for this purpose, carefully skim off the top six ounces from a quart bottle of milk; to this add twenty-four ounces of water which has been boiled and cooled, and in which has been dissolved three teaspoonfuls of granulated or six of milk sugar; next add a pinch of bicarbonate of soda and a small pinch of salt; mix this all thoroughly, and pour enough for each feeding into ten separate bottle& Then cork the bottles family with cotton and either Pasteurize the milk or stand it on the ice.

"For the second month. Skim off six ounces of cream, then pour off three ounces of milk; add twenty-four ounces of water and the same amount of sugar, salt and soda as above; mix and bottle.

"For the third and fourth months. Cream, six ounces; milk, six Ounces; water, twelve ounces; barley or oatmeal gruel, twelve ounces; sugar, salt and soda as usual, etc.

Plain Milk Formulas

"Pour the entire quart of bottled milk out into a clean pitcher and then back into the bottle several times, thus thoroughly mixing the milk; then take:
"For the first month. Six ounces of milk, twenty-four ounces of barley-water, half a tablespoonful of granulated or one of milk sugar, a pinch of bicarbonate of soda; mix all well together and pour the proper number of ounces into separate bottles, and either Pasteurize or place on ice.

"For the second month. Nine ounces of milk, twenty-one ounces of barley-water, one tablespoonful of sugar, and a pinch of soda."

Physicians would never think of giving such advice as this, if they were acquainted with natural dietetics founded on exact and complete analyses made by food chemists of the nature cure school.

I have already called attention to the fact that food chemistry, whether practiced in allopathic colleges, in great sanitariums or by vegetarian food reformers, deals with proteids, starches, fats and sugars only, and leaves entirely out of consideration the all important mineral elements or organic salts of potassium, sodium, iron, lime and magnesium.*

*This was true at the time this article was published in the Nature Cure Magazine.)

On these five positive mineral salts, as we have shown, depend all the important vital functions of the human organism, while proteids, starches, fats and sugars serve only as building and fuel material.

The digestion of the proteid and carbohydrate foods, as well as the elimination of the waste matter resulting there from, depends upon the positive organic mineral salts.

Study carefully these recipes for baby feeding, taken from the Ladies' Home Journal, and compare the mixtures with the analyses of cow's milk and human milk in the accompanying tables.

Let us consider the "top milk" mixture, prescribed for the first month. The cream rising to the top is almost pure fat. The all-important mineral elements plus the nourishing milk sugar and proteids remain in the skimmed milk, which is looked upon as worthless and fed to the pigs.

Our food analyses (see tables in Volume III, Cook Book) show that the ordinary brands of flour are almost devoid of mineral elements. Furthermore, one teaspoonful of barley to one pint of hot water does not mean much in food values. Where in these six ounces of cream (fat) and twenty-four ounces of barley water is baby to get the necessary amount of sugar for fuel material, of proteid for tissue-building, of lime for bone-building, of iron for oxygen-carrying, and of sodium, magnesium and potassium for the processes of elimination?

It seems that these deficiencies are intended to be overcome by baking soda, mineral table salt and the lime water, so generally prescribed by physicians. Many times I have demonstrated that inorganic mineral salts, with the possible exception of a little table salt, should not enter the animal or human organism, that these salts must first be organized,
made alive in the plant or animal cell, before they are wholesome food for animals or human beings. I have shown that, taken habitually in the mineral form, these salts accumulate in the human body, act as irritants and poisons and reveal their presence in the iris of the eye.

I fail to understand why the tender and sensitive organism of the newborn infant should be encumbered with inorganic minerals while cow's milk contains them in ideal form, made alive first in the grasses and grains, then still more highly organized and magnetized in the body of the animal.

It is bad enough to give mineral sodium, lime and table salt to an adult, but it is little short of criminal to give them to babies under the guise of foods and medicines.

The cream mixtures are readily digested, because there is not much to digest. The fact that infants thus fed cry for food continually is good evidence that their needs are not satisfied. Babies fed with this sort of slop grow fat for a while. The watery food inevitably produces fatty degeneration. This for a season swamps the little body with unhealthy fat. But the first crisis which happens along often takes away not only the unnatural fat, but the baby also.

The artificial mixtures contain entirely too much water in proportion to nourishing elements. The resulting malnutrition and the constant irritation caused by the inorganic minerals result in chronic diarrhea or constipation.

**The Right Way**

The best food for the newborn and growing infant is undoubtedly the mother's milk, provided that she is herself in fairly good health. Unfortunately, many mothers are unable to nurse their offspring, and if a healthy wet nurse cannot be secured, other food must be provided.

The best substitute for human milk, without question, is cow's milk, fresh, pure and undiluted, as it comes from the animal.

"Why", indignantly exclaims the trained nurse, when we give these instructions, "undiluted cow's milk is altogether too rich, it is indigestible for baby; if the milk is not boiled or pasteurized, germs and bacilli will surely create infectious diseases".

To this we answer: Our analyses show that the difference in composition between cow's milk and human milk is not enough to affect the infant. The danger lies not so much in overfeeding on "rich" cow's milk as in underfeeding on watery milk and cereal dilutions, and in poisoning the little body with inorganic minerals.

As regards germ infection and the necessity for pasteurizing the milk, the menace to health and life is greater through
malnutrition than through germs and bacteria. Germs we cannot escape, not even if we were surrounded on all sides by walls of air-purifying and antiseptic materials.*

*Since the foregoing was written we have learned that low vitality and morbid soil will develop perfectly normal microzyma into so-called disease germs.

One of the foremost French bacteriologists claims that in the mouths of infants shortly after birth he has found almost every disease bacillus known to medical science.

William Osler; M.D., to whom the English language is indebted for the verb "to oslerize," says in *The Principals and Practice of Medicine* on page 151, in the chapter on Diphtheria:

"The presence of the Klebs-Loeffler bacillus is regarded by bacteriologists as the sole criterion of true diphtheria, and as this organism may be associated with all grades of throat affections, from a simple catarrh to a sloughing, gangrenous process, it is evident that in many instances there will be a striking discrepancy between the clinical and the bacteriological diagnosis."

In the first part of this sentence he states that bacteriologists regard as the sole criterion for the diagnosis of diphtheria the Klebs-Loeffler, or diphtheria, bacillus; in the last part of the sentence he admits that this bacillus is found in even slight catarrhal conditions, and he might add that it is found just as frequently in the mouth and throat of healthy infants and adults. This is a good example of "orthodox" scientific reasoning.

If germs and bacilli of themselves could destroy health and life, the human race would in a short time become extinct. Disease germs are omnipresent. They permeate the tissues of our bodies and in the intestinal tract swarm by millions. Whether they prevail depends upon natural resistance, or reserve force, and upon the disease soils in the system. The air we breathe is saturated with all sorts of disease germs or their microzyma.

Since baby cannot escape germ invasion, the real problem is how to increase the resistance of the little organism and how to purify it of morbid matter so that disease germs will not find anything to feed on.

Resistance depends largely upon proper nutrition. Diluted, watery milk, contaminated by inorganic minerals, is not a good nutrient; its nutritive value is still more reduced by pasteurizing or boiling. Heating milk or any other proteid food above 1500 F. coagulates the albumen, disorganizes organic compounds, precipitates salts and dissipates the life elements. This reduces the nourishing value and digestibility of the milk.

Nature does not provide the young animal with boiled or
pasteurized milk, and we should not lower food values by such methods.*

* It is now admitted that pasteurization and boiling kills "newly discovered vitamins" which are the "life elements" constantly referred to in my earlier writings.

I do not wish to intimate, however, that scrupulous care and cleanliness should not be exercised in the selection and handling of the milk.

Wherever possible, secure the milk of a single healthy cow that grazes on green pastures or is fed on normal clean food mixtures. Milk from cows kept in stables and fed on brewery and distillery slops and other refuse should not be used.

Every vessel and utensil with which the milk comes in contact must be carefully scoured, submerged in boiling water, drained and kept in a light, airy place.

The nursing bottle, after each feeding, must be taken apart and carefully scrubbed, inside and out, in hot water with an addition of a little soda. It should then be left in pure, cold water, until the next feeding time.

2. When to Feed. Physicians quite generally recommend feedings at stated hours, in fixed quantities.

This is altogether wrong, it establishes at once the stuffing habit, does not permit the development of natural desire and its regulation. The infant very soon becomes accustomed to eating at certain times, whether it really needs the food or not.

Food should not be given until there is an actual demand for it, which will express itself in real hunger. By careful observation and experiment the mother will soon learn to distinguish the ordinary crying of the baby and the desire for food expressed by it. If this practice of feeding only when there is a natural desire for food is strictly followed, the infant will soon establish its own regular feeding times, usually at intervals of about three or four hours in the daytime. The stomach digestion of a feeding of milk will require about three hours, therefore a minimum of that much time should be allowed between feedings after the first few weeks.

If the mother can nurse her baby, it should be put to the breast upon awakening from its first sleep, either before or after bathing and dressing.

The first secretion of the breasts (colostrum) is not really a food, but performs an important function in cleansing the intestinal tract and preparing the digestive system to properly digest and assimilate the milk when it comes, usually about the third day.

3. How to Feed. If artificial feeding must be resorted to, no food at all should be given, except a few teaspoonfuls of water, during the first twenty-four hours after birth. During
the next few days, cow's milk should be given, well diluted—about one-half milk and one-half filtered or boiled water. From week to week the amount of water should be reduced until at the end of the second month the baby takes cow's milk undiluted.

4. Night Feeding. In the nighttime feeding should not be encouraged. During the first four months it is advisable to feed not more than once during the night. After that the child should be weaned from the habit entirely. This will be facilitated by giving a drink of water instead of milk.

5. Amount of Food. Discretion should be observed in determining the amount of food. Do not induce the baby to take as much as possible, rather as little as possible. Its welfare does not depend upon the amount of food consumed, but upon the amount which it can easily digest and assimilate.

When more food is given than the digestive organs can take care of, the entire mass may ferment and sour.

6. Grain Extracts. If undiluted milk proves too rich, grain water may be added. In order to prepare this, take clean grain as it comes from the field, crush it in a hand grain mill or a new coffee mill, take three tablespoonfuls of the crushed grain to one pint of cold water, and boil on the stove for one hour; or in the fireless cooker for two or three hours, in which ease use a little more water at the start. While the gruel is boiling over the fire, add enough water to allow for evaporation and absorption. When thoroughly cooked, strain the gruel through a fine cloth or sieve. Add one tablespoonful, or more if necessary, to each milk feeding.

When baby is constipated, add to the milk, grain extract made from oats, and frequently cool the bowels with cold water. This will cure the most stubborn constipation. If the bowels are too loose, add to the milk, extract made from barley or wheat.

The small particles of hulls in the grain extracts improve digestion and evacuation, in a mechanical manner. They permeate the curds and keep them from coagulating too solidly, thereby facilitating the penetration of digestive juices; they also exert a mild stimulation on the walls of the intestines, thereby increasing the peristalsis of the bowels and evacuation of feces.

7. Baby's Natural Medicines. Fruit juices and scraped raw ripe pear or apple and the pulp of cooked fruits such as prunes or figs without addition of sugar or sweetening of any kind, are baby's finest medicines. They increase the supply of organic salts for blood, nerve and bone building and for purposes of elimination. They are nature's own chologogues, laxatives, tonics and antiseptics. They keep the little body sweet and wholesome. All babies under our care receive fruit juices beginning with the second week.
During the first two months, give one teaspoonful of orange juice, grape fruit juice or prune juice, one hour before or after each nursing. After the second month, gradually increase the amounts of fruit juices and begin to add raw pear or apple scraped with a spoon or dull knife, or the mashed pulp of fully ripened peach or grapes.

**8. Weaning the Baby.** Nursing infants should be weaned from the breast after the eighth or ninth month. From the sixth or seventh month, both nursing and bottle-fed babies should begin to take some solid food. The best of these to begin with are whole-grain cereals, gruels, raw and cooked fruits and tender vegetables in small amounts. Mealy baked potato is one of the best foods, better than the cereals.

**9. Feeding After First Year.** After the lapse of the first year, the solid foods are gradually increased and the milk reduced in quantity. Eggs should not be given before the eighteenth month, then soft-boiled or poached. During the second and third year half an egg twice or three times a week is sufficient; after that an egg at a time may be given once or twice a week.

Meat and all other foods prepared from the dead animal carcass are bad enough for adults, but it is inexcusable to give them to tender infants and children.

Dog fanciers, when they sell a valuable canine, usually advise the buyer not to give the animal any meat before the second year, lest it become a victim of distemper; and dogs are naturally meat eaters.

Well informed physicians now generally advise not to give meat to children before the fifth or sixth year. They have learned this much from the nature cure people.

Foods undoubtedly have a powerful influence, not only on the physical body, but also on the mentality and the emotions. These problems will be interesting subjects of investigation for the food chemist and psychologist of the future. In general, we may say that flesh foods are stimulating and feed the passional nature, while fruits and tender vegetables refine and stimulate brain and nerve matter as well as the intellectual, emotional and spiritual activities. Cereals, nuts and pulses build and repair the physical body and supply the body with heat and muscular energy.

The majority of animals adhere strictly to one kind of food, and therefore faithfully exhibit in their mental and emotional characteristics the effects of different food materials. Ferociousness we find personified in the carnivorous bulldog, lion, tiger and panther (that is why soldiers are fed on meat three times a day); gluttony and omnivorous voraciousness in the hog, chicken and hyena; cold-blooded cunning in the fox, and cruelty in the cat. The intelligence of the carnivorous animals displays itself mainly in the cruel cunning with which they stalk their living prey. It resembles in quality the low
intelligence of the human criminal.

Personifications of great physical strength, intelligence, endurance, patience, gentleness, fidelity, affection and self-control, we find among the vegetarian animals. The beaver, the arboreal ape and the elephant are especially noted for their intelligence; deer, antelope and sheep for gentleness; the horse for its almost human intelligence, affection and fidelity oxen, elephants and camels for their great strength and endurance.

**Meat is detrimental to the child in every way**, physically, mentally and morally. The poisonous acids and alkaloids which it contains clog the capillary circulation, causing anemia, coldness of the extremities and defective elimination through the skin. This results in congestion in the interior organs, high blood pressure in brain and heart, headaches, nervousness, irritability, tendency to fevers, inflammations and catarrhal conditions.

With the meat, the child often absorbs the eggs of worms, tubercular bacilli, and other parasites and disease germs. Certain forms of epilepsy, St. Vitus' dance and hysterical conditions are due to uric acid poisoning and to other pathogenic materials and ptomains contained in flesh foods. Such patients, in times of crises, frequently emit pronounced odors of raw meat or uric acid. Strictly vegetarian diet, combined with other eliminative natural methods of treatment, cures the majority of these cases.

Most of these poisonous acids, alkaloids and ptomains contained in the flesh of dead animals are powerful stimulants. I have frequently noticed that people who have abstained from meat for a long time, when they first partake of it again experience sensations and exhibit symptoms resembling those of alcoholic intoxication.

We have learned that these stimulating extractives of flesh foods chemically closely resemble caffeine, thein and nicotine. The use of one or more of these stimulants invariably creates a craving for the others. This explains why a heavy meat eater is usually a confirmed coffee drinker or inveterate smoker, and vice versa; and why we find it almost impossible to wean people from one of these stimulants as long as they persist in taking the others.

The legumes or pulses—peas, beans and lentils—are close seconds to meat in acid-producing qualities. Eggs contain considerable ready-made uric acid and a great deal of sulfur and phosphorus. These may become dangerous to the organism. For these reasons, meats, legumes and eggs are always danger foods for the child.

Children brought up on such foods will show the effects in nervousness, irritability, lack of self-control, craving for cigarettes and alcoholic stimulants. The most serious aspect of this question lies in the stimulative influence of meat poisons
on the sex centers. It is a well known fact, verified by close
observation, that flesh foods stimulate the sexual passions to a
marked degree. This tendency is greatly increased by the use
of coffee, tea and alcoholic stimulants in the form of wines,
liquors or medicines. If the sensitive nervous organism of a
child is overwrought by these powerful irritants, there can be
but one result; precocious sexual awakening.

From the third year the child may gradually adopt with
slight appropriate modifications, a diet as outlined under Sec.
I, No. 10, and Sec. X, No.7.

SECTION XL

Exercises in Infancy

1. Exercises in Infancy. Proper exercise is important from
the very beginning of life. A baby will follow its natural
instincts for exercise if allowed to do so, by working its arms
and legs and writhing its little body in all directions, if not
unduly hampered by tight clothing and bandages. A few nude
air baths every day will afford excellent opportunity for
baby's gymnastic stunts.

After he is a few months old he may be placed on his
stomach, when he will exert himself vigorously by trying to
raise his head, to turn around, or to raise himself with his
arms. He will soon learn to roll over and to creep lie nay now
be pulled up gently by his arms and lowered again a number
of times in succession.

When three or four months old he may be lifted by one arm
or by both arms; by the right arm and left leg, or by the left
arm and right leg. When the baby is six or eight months old,
he should be strong enough to rise from his back to a sitting
position. This may be encouraged by holding down the feet. I
have known a number of nature cure babies who at six
months of age clung tightly to a stick while being lifted a few
feet from the bed. Another good exercise greatly enjoyed
by the youngsters is to roll them back and forth on a bed.

The average healthy child will secure ample exercise while
learning to walk and run and while playing with simple toys
or with other children; but this may be supplemented to good
advantage by special exercises devised by the father and
mother. Nothing is better for the health and happiness of both
parents and children than to join in merry romp and play.

Between two and five years of age the child may be taught
more difficult stunts, performed either by himself or with the
assistance of the father or mother; but swinging the child
high overhead, throwing him up and catching and other
dangerous tricks should be avoided. They are risky and
have very little effect in developing the body of the child. The
best exercise at this age consists in outdoor play and games.
From the sixth year, the question of exercise becomes a more important one, especially since the children are confined for many hours in school rooms. If exercise at this time of life, through play and games and special gymnastics, is neglected, it may affect health, strength and efficiency of the child for life.

Those of good physique and ample strength may gradually take up and practice the exercises for adults outlined in sections XXI, XXII, XXIII, XXIV.

2. **High Chair.** A baby should not be put in a high chair until he is quite well able to hold the spine and head erect, and should never be left in a chair for any length of time. If a baby is forced to maintain a rigid, sitting position for a considerable time, before the bones and muscles are sufficiently developed, this may produce deformity of the spine. Maids and nurses, if not properly supervised, sometimes fasten a baby in a high chair and leave him there to take care of himself for long periods.

3. **Toys.** Since most babies have a habit of putting everything into their mouths, toys must be selected that can do no harm. They should have no paint, no sharp points or corners which might hurt the eyes or mouth, and must be of material which can be easily and thoroughly cleansed. Hairy and woolly playthings are unsafe, being unclean and germ carriers. Objects small enough to be swallowed must never be put within baby's reach. The simpler the playthings the better; a few clothespins, empty spools, or other simple objects are better than expensive toys.

**SECTION XLI**

**Baby's Ailments**

1. **Hernia** As a result of a weakly or sickly condition of the mother during pregnancy and of faulty prenatal management, many children are born ruptured. So far I have not known a single nature cure baby that was born ruptured. Such defects are due to weakness of the tissues. This results from mineral starvation. The tissue walls contain too much mortar (protein) and not enough building stone (mineral salts). Prevention of hernia, therefore, lies mainly in proper diet of the pregnant mother, but all the rest of the prenatal regimen described in these pages is of great importance in preventing this and other ailments and deformities.

There are three principal points at which rupture or hernia may take place in infancy—at the navel, in the groin, and at the line between the navel and the lower end of the sternum. Other kinds of ruptures are extremely rare.
2. **Umbilical Hernia** This is a protrusion of the intestine at the navel. It is the most common rupture in infancy. Pulling on the cord during childbirth, urging at stool or violent crying may result in rupture. The umbilical ring first expands and this forms a pouch into which one of the folds of the small intestine protrudes.

Treatment: Of primary importance is the diet as outlined herein. The baby must have plenty of fruit juices in order to reinforce the mineral salts in the milk. Cold bathing is very beneficial. The rupture itself should be cleansed several times a day with warm water. This must be followed by a wash with cold water mixed with lemon juice. Gentle, passive exercise, such as raising, lowering and twisting the limbs from side to side, also raising and lowering the body while supporting the shoulders and head, is of especial value.

The rupture must be reduced and kept from protruding by placing over it a large button or other article of similar shape, wrapped in gauze and held in place by broad strips of adhesive plaster. The adhesive tape is fastened over the button crosswise and must be applied in such a manner as to draw the skin from all sides over the rupture. Instead of the button, a compress made of gauze may be laid over the rupture and held in place by one broad adhesive strip. The covering of the rupture must be removed and renewed every day in order to allow cleansing, as before described.

When the child is old enough to exercise by himself, he should be taught special movements of the body and the limbs which develop the muscles of the abdominal region.

3. **Ventral Hernia.** This occurs along the middle line of the body between the navel and the breastbone, sometimes below the navel. The rupture may not be larger than the size of a pea or small marble, and may disappear on pressure. The treatment is the same as that of umbilical hernia.

4. **Inguinal and Scrotal Hernia** occur in infancy or in adult life; sometimes the inguinal canal does not close after the descent of the testes from the abdominal cavity into the scrotum, and the intestine descends through the open canal, thus producing the rupture. These forms of hernia become aggravated by coughing. They can be reduced immediately with gentle manipulation while the patient is lying on his back. This kind of rupture may be distinguished from hydrocele by the fact that in reducing it goes back easily with a gurgling sound. Hydrocele is not affected by coughing. A hernia is opaque to transmitted light; hydrocele, transparent.

These ruptures should be protected with a well-fitting truss. This has to be removed daily for cleansing of the parts. Appropriate exercises, passive and active, together with cooling sitz baths and washes with cold water and lemon juice are the best remedies for these, as well as of other forms of rupture.
5. **Congenital Hernia** occurs in the form of inguinal hernia and has to be treated in the same way. Ruptures of any kind must be reduced and properly supported. Constipation and consequent urging at stool may cause or aggravate any form of hernia and must, therefore, be overcome by the right treatment described under section XXVI, No.1.

6. **Colic.** This is usually caused by indigestion due to overfeeding, improper feeding, or too frequent feeding. The intestines are distended with gas, giving rise to a severe pain. The baby cries sharply, alternately drawing its legs up to the body and kicking them away. One of the quickest means of relief is a small enema of warm water and gentle circular massage of the abdomen from right to left. Food should be withheld until the symptoms have disappeared. The giving of milk or other food may quiet the attack temporarily, but the pain is apt to return with greater intensity. Warm water may be given if the baby will swallow it.

A baby managed in the natural way prenatally and postnatally is not likely to suffer from this ailment. Constipated babies are more prone to it than others.

Colic may also be caused by sudden chilling. In that case a warm bath for five or ten minutes, followed by gentle body massage will bring about a warm reaction.

7. **Convulsions.** These cause a great deal of anxiety to the fond mother. They are always reflex symptoms of some slight or serious internal disturbance due to wrong management. They commonly result from some form of auto-intoxication caused by digestive disturbances, and the resulting systemic or drug poisoning. An inactive condition of the skin, bowels or kidneys will favor auto-intoxication and convulsions. If proper care is taken to keep the system pure, and the organs of elimination in active condition, convulsions will not occur.

The best treatment during an attack is a quick, cold rub all over the body; application of a whole body or trunk pack; gentle soothing magnetic massage, and neurotherapy treatment. These treatments draw the blood into the surface and relieve congestion in the brain and nervous system.

8. **Ailments of Teething.** Many ailments of children are laid to teething, but this is a mistake. Well managed, healthy babies go through the teething period without any trouble whatsoever. This is practically always true of nature cure babies. When, however, the little body is heavily encumbered with hereditary and acquired morbid materials, food poisons and disease taints, the process of teething will not run its natural course and may precipitate any form of disease crisis.

When teething is difficult, it is frequently associated with digestive disturbances. Diarrhea may alternate with constipation and vomiting is of common occurrence. The baby may be restless and fretful. He tries continually to bite on something in order to facilitate the projection of the teeth.
through the hardened gums.

No teething lotions or soothing medicines of any kind should be given for the relief of pain in teething. They all contain poisonous sedatives which benumb and paralyze the nerves and have serious after effects upon the system. They usually contain opium in some form, or other narcotic drugs.

The only way to prevent these and other infantile ailments is to keep the little body as nearly normal as possible through the natural treatment described in these pages. If this is closely adhered to, it will prevent, in many cases, the development of even measles and other common eliminative infantile ailments.

During this critical period in the baby's life the diet must be extra light; starchy food should be reduced to a minimum and replaced by raw and cooked fruits and vegetables juices. Cooling sitz baths will help to keep the bowels active and to abate internal fever.

9. Acute Catarrhal Disease. Acute catarrhal diseases of infancy such as croup, cold in the head, acute bronchitis and whooping cough, are different forms of acute elimination through which Nature tries to purify the little body from hereditary and acquired accumulations of morbid matter, systemic poisons and disease taints.

In accordance with this conception of acute diseases, as purifying, healing efforts of Nature, we would not do anything to check or suppress elimination but cooperate with Nature in her purifying, healing efforts. How we do this has been fully explained in other parts of this volume. (Section VIII)

The natural treatment is very much the same in all acute inflammatory ailments. Feeding must be reduced to a minimum. If the baby does not insist upon eating, nothing should be given except water with acid or sub-acid fruit juices, such as lime, lemon, grape fruit and orange. If the temperature does not run high, say not above 100 or 102 deg, frequent ablutions with cold water at intervals of from one to two hours will be sufficient to promote heat radiation and elimination of morbid matter through the skin and other organs of elimination. If the temperature runs' higher, say between 102 and 105 deg, wet packs must be applied, and renewed when they become hot or dry.

The wet packs are of especial value in all kinds of cough; whether it be the ordinary cough, croupy cough or whooping cough. A whole body or trunk pack, with or without a throat pack, will give almost instant relief. In many instances where baby is making the night hideous for the anxious mother, with it's coughing, a well-applied whole body pack, or a combination trunk and throat pack, will relieve the coughing almost instantly, and induce restful sleep.
In serious cases it is always advisable to call in a natural therapist or some other drugless physician, if one can be reached.

The mother should not forget that all acute diseases, after they have once developed, must run their natural course. She must, therefore, not become impatient and lose faith in the natural treatment if it takes a week or more to cure a common cold in the head or an attack of bronchitis, or if it takes from two to eight weeks to cure a case of whooping cough. Serenity, patience and cheerfulness are the primary requisites of the nature cure physician.

PART IV

BABY BOOK

Natural Therapeutics has undoubtedly solved the problem of treating human ailments. All other schools and systems will in time have to adopt the natural way. It is the hub of the healing art; all therapeutic methods radiate from it like spokes from a wheel.

Natural Therapeutics, however, has something better to give than treatment of disease, and that is prevention of disease. If children were brought into this world in the manner ordained by Nature and reared in harmony with the teachings of natural philosophy, disease would soon be a thing of the past. Human beings would then enjoy good health and be as beautiful and perfect in their kind as are animals, which live in the freedom of Nature, guided by instinct and therefore in harmony with the laws of their being.

We must begin, then, with prevention, for prevention is always easier and cheaper, than cure. But where must we begin to study the prevention of disease? Some will say, "At birth, because that is the beginning of life." Not so: that would be too late. The mould is made and the foundation laid for health or disease, for happiness or suffering, for efficiency or deficiency, before the human being in process of creation sees the light of day.

"Then," it may be said, "we must begin with prenatal influence, for the physical, mental, emotional and moral habits of the mother influence powerfully the development of the new life she is carrying." True—but we must start earlier than that. The making of the human being begins with mating and conception. All subsequent development depends upon the right start.

SECTION XXXII

Heredity

1. Importance of Correct Mating. Of primary importance in the sacred rite of procreation, as already intimated, is mating. This should take place only between descendants of the same subrace, or of closely related subraces such as the Indo-Caucasian and Celtic.

If the racial descent of the marriage partners is so far removed that it has produced pronounced differences in racial
characteristic—as in the case of the swarthy Mexican and white skinned Englishwoman, or the dark eyed Magyar and blue-eyed Scandinavian—then procreation becomes miscegenation and degenerates into mongrelization of the offspring. Everywhere in the animal and human kingdoms Nature has set the mark of disapproval on the mongrel. The offspring of miscegenation is doomed to deterioration and extinction unless assimilation of the elements of a lower race by a higher takes place sparingly and gradually.

The law of racial purity may be summed up as follows: When a member of a higher race cohabits with a descendant of a lower race, the offspring of the union loses more or less the characteristics of the higher race and reverts in physical, mental and moral traits to the level of the lower race.

The constructive results of racial purity are evident in Hindus of the higher castes; in that portion of the Jewish race which in mating has faithfully adhered to the Law of Moses, and in the blond and blue-eyed remnants of the Indo-Caucasian and Celtic races in Northern Europe and North America. The destructive results of miscegenation are plainly evident in the mongrelized population of Mexico and everywhere in the half-breed and many kinds of mixed breeds. These usually fall below the physical, mental and moral standards of the parent stock, and almost invariably revert to the customs and habits of the inferior race.

2. Use Heredity. Use heredity deals with the transmission to offspring of acquired physical, mental and moral characteristics of the parents. According to this law as it has been formulated, the chances of the offspring for long life, health, mental efficiency and moral stamina, other conditions being favorable, are better in direct ratio to the advancing age of the parents at the time of conception. While this is contrary to popular opinion, which assumes that younger parents produce more perfect offspring than older ones, the fact of use heredity is proved, both in the animal and human kingdom, by common observation and statistical evidence.

The working of the law is based on the fact that the procreative elements of the parents, or rather the microzyma of those elements, cannot contain the impress of physical, mental and psychical characteristics which at the time of procreation were not developed in the threefold organisms of father and mother.

The age of the father at conception is called the "birth age" of the offspring and determines its birth rank. While the father and previous male ancestors, for reasons hereafter explained, seem to exert greater control over the mental and physical characteristics, the mother furnishes the nutrient soil for physical growth. This does not mean that she exerts no control over the mental and psychical characteristics of the offspring; in addition to her influence through use heredity she has added opportunities through prenatal influence and postnatal training.
According to this law, then, the chances of the offspring for excellent physical, mental and moral development become better as the age of the father at the time of procreation advances beyond thirty five; while the physical condition of the mother for reproductive function is best below thirty five years.

But we must not overlook the fact that too great a discrepancy of age between the man and woman may become the cause of physical and mental incompatibility, of aversion and great unhappiness, especially on the part of the younger woman.

Extensive statistical evidence seems to prove that the birth age of the mother has been of less importance than that of the father. As will be shown in Natural Eugenics, the majority of famous men in all lines or human endeavor had old male ancestors, while the mothers and previous female ancestors were of much younger age at the time of conception.

This may be accounted for by the following reasons:

The man is usually considerably older than the woman at the time of marriage. Men, as a rule, devote much more time and effort to acquiring a scientific, professional or business education than do women. This has been true in the past more than it will be in the future. Thrown early into the competitive struggle of life men generally have had to make greater mental and physical effort than have women.

These points are of considerable importance because it has been proved that it is not inherited brain mass and mental capacity, but strenuous and persistent effort that intensifies use heredity. The earlier this begins and the longer it continues before procreation takes place, the better the chances of the offspring for physical, mental and moral capacity.

The reproductivity of the mother has usually ceased at thirty-five. Though she be capable of childbearing a few years longer, usually conception has been avoided after that age. Men under favorable conditions remain reproductive to advanced age. Some of the world's greatest men descended from fathers over sixty years old.

That intellectual and creative capacity has followed the male line of descent rather than the female line, is indicated by the fact that the high intellectual capacity of many eminent men has skipped their daughters to reappear in male descendants. This may be partly accounted for by the fact that the daughters in their limited spheres of activity have not had the opportunity to unfold inherent intellectual capacity to any conspicuous degree.

There has been a tendency in some quarters to criticize the general entrance of women into professional and commercial life and to dilate upon the adverse influence this will have
upon womanly characteristics and family life.

In the light of the knowledge we possess upon the subject of use heredity, it is safe to say that any such problematical drawbacks will be far outweighed by the general postponement of the marriage age. This will insure not only better physical fitness but also higher intellectual development and greater moral stamina on both sides of parentage.

The tremendous benefits which this increased hereditary endowment will confer upon future generations cannot be overestimated. Greater intellectual and economic equality between the sexes will emancipate woman from degrading sexual subservience. Under the old order, sex appeal was too often her only stock in trade by which to attract and hold the male and thus to secure a living. Economic independence will insure greater consideration and higher esteem for the woman on the part of the man. It will go a long ways toward solving the problem of birth control in a natural way, by leaving it more largely to the judgment of the mother.

We find the law of use heredity according to birth age verified in the intelligence and moral development or obliquity of races, nations and tribes all over the earth—The lower the average birth age of a race or nation, the lower, other things being equal, the intellectual and moral development The greatest development and efficiency is found among those nations where marriage is delayed to a later age through custom, economic necessity, professional or military training.

The following quotation from "Control of Heredity", by Casper Lavater Redfield, is of interest in this connection:

"In general it may be said that wherever there are no restraints upon the sexual propensities, as with the Digger Indians, the Fuegians, the Andamanese, the Wauraus of the Guianas, the Bushmen and the tribes along the Gabbon river, there we find reproduction taking place at the earliest possible age, and the lowest grade of intelligence. Where we find some special circumstances or customs that delay the age at which reproduction takes place, as with the Patagonians, the North American Indian and the Polynesians, there we find considerably higher grade of intelligence.

"Where we find the custom of marrying late in life, as was customary with the Greeks and the Romans, there we find a very high grade of intelligence. And where we find a fortuitous succession of very late births, there we find the very great men of the world's history.

"In other words, the longer the time in which the individuals have in which to use, develop and strengthen their brains before reproduction begins, the greater and more powerful are the brains of their descendants."

In Volume IV of this Series I shall quote elaborate and
highly interesting statistics from Redfield, which reveal the effects of the various birth ages on physical, mental and moral characteristics. I shall confine myself, for the present, to the statement that, with few exceptions, the great artists, scientists, philosophers, statesmen and philanthropists were born from fathers whose ages ranged from forty to sixty-five years at the time of the procreation of their famous offspring.

The existence of these laws and principles as facts in nature is very evident in the training of racehorses and of other animals along certain lines of proficiency.

3. Pernicious Heredity. The effects of deteriorating and destructive heredity prenatal and congenital influences have been traced and commented upon in so many different ways that I do not believe it necessary to enter deeply into this phase of the subject. Various authors have filled entire volumes with the unsavory family histories of the descendants of the Jutes, Ishmaels and other drunkards, prostitutes, degenerates and criminals, which prove positively the transmission of morbid and pernicious traits through successive generations. It has been proved statistically beyond the shadow of a doubt that youthful delinquency, pauperism and criminality are the aftermath of immature marriages.

The laws of use heredity and prenatal influence, like all other natural laws and principles, manifest along opposite lines of expression. It remains for us to determine whether we shall align ourselves with their destructive or constructive activities. The effects upon ourselves and our offspring will show accordingly.

If I succeed in arousing the consciousness of prospective fathers and mothers to the glorious privileges and enormous responsibilities which these laws of nature confer upon them, then my labor will not have been in vain and I shall feel deeply gratified.

SECTION XXXIII

1. The Creative Alchemy of Love and Affection

Procreation—as is the case with everything else pertaining to the constituents and functions of the human entity—takes place on three planes of being, the material (physical and spiritual), the mental and the psychical planes. Which of these elements shall predominate in the offspring depends upon the mixture and adjustment of qualities in the triune makeup of the mating couple. In order to fulfill the law and to draw the divine blessing upon themselves and the fruit of their union the partners in the procreative function must be united by the bonds of love, or at least by the ties of true affection.
The source of creative genius is love and wisdom, and the essence of intelligence and power is sincerity and goodness. Without these, intelligence degenerates into selfish cunning, power into self-destructive brute force. The spring cannot rise higher than its source; its water cannot be pure and wholesome when contaminated by impure admixtures from filthy surroundings.

It is not generally known that use heredity pertains to intellectual and psychical qualities, as well as to the physical material. Animalism breeds nothing but selfish animalism. The vampire who craves and absorbs the love of its victims and robs them of vital energy, without being capable of feeling or bestowing affection, is the child of a discordant union—of brute animalism on the part of the man, of secret aversion and hatred, usually, on the part of the woman. These bestial and degrading tendencies on the one side, and unrequited love craving on the other, breed sex perversion, and propagate the harpies who delight in the seductive power of superficial beauty, while gloating over the weakness and ruin of their victims.

True love and affection, paired with intelligence and goodness; liberate the creative elements necessary to the production of perfect offspring.

The finer qualities of mind and soul open the fountains of life on the higher planes, liberate and harmonize the male and female procreative fluids, and charge them with the purest and most potent intellectual, spiritual and psychical elements.

The divine fire of creative genius burns only in the love aura of truly mated couples. It is true that these are rare under our artificial, unrighteous social institutions, and that accounts for the rarity of complete manhood and womanhood.

Perfect offspring, endowed with beauty and power of body, mind and soul, destined to shed through life a radiance of health, happiness and helpfulness—to love and be loved—issues only from the union of love and affection with intelligence and goodness.

"Love lieth at the foundation" (of all that is). "Love is passion, enthusiasm, affection, heat, fire, soul—God."

To the extent that love enters into the holy rite, to that extent its attributes will be absorbed in the threefold organism of the woman and become active in the child building in her womb. While she loves her man more than ever, her most passionate affection is centered in the new being in process of development. On it she bestows the purest and best in her food and drink, in her thoughts, emotions and secret desires. Fear, worry, anxiety, jealousy and hatred are strangers to her soul; these are the emanations of the lower spheres—she lives in heaven.

Somebody endowed with deep insight into these matters has
said:

"Whatever male and female shall truly will for, hopefully pray for and earnestly yearn for, when love pure and holy is the nuptive ascendant, in form, passionate, affectional, divine and volitional, that prayer shall be granted, and the boon be given—but the prayer must precede."

What are the direct effects of the marital rite upon the participants? If the sex attraction operates on the physical material plane only, if lust instead of love presides at the matrimonial feast, then temporary gratification of erotic craving will be followed inevitably by monotony, satiety, gradual revulsion and aversion, culminating in a morbid craving for change and variety. The partners in carnal self-indulgence are intuitively aware of these tendencies to marital unfaithfulness, and, therefore, easily dominated by distrust and jealousy.

The procreative function is attended by complete satisfaction, buoyancy of body and mind and lasting happiness only when sex attraction operates on the higher and highest planes of being, as well as on the lower, when desire and impulse are operative on both sides. Thus only will the generative function fulfill its sacred purpose and confer the highest possible benefits upon parents and offspring.

The woman, being the more highly sensitized, must be responsive to the call of holy passion. To force unwilling compliance will ruin the woman, kill her love and curse her offspring. Balzac says: "He who begins with his wife by a rape is a lost man." It is impossible for a wife to love unless she is won, not forced to compliance.

2. Sexual Intercourse During Pregnancy. Sexual intercourse should be considered the most sacred function of the human entity. From the highest and best viewpoint it should be exercised only for the propagation of offspring. However, considering the present stage of ethical and moral development, temperate indulgence may not be wholly condemned. Excessive intercourse is always weakening and harmful to both participants. We must remember that the sex fluid is the carrier of the life force. It is that which constitutes strength, resistance to disease, initiative and genius. During abstinence from intercourse the sex fluids with their creative energy are absorbed through the inguinal glands into the organism and increase physical, mental, moral and spiritual capacity and energy.

Set rules for frequency of intercourse cannot be given. This must depend entirely upon individual conditions. One safe rule is that after indulgence there should be no feeling of satiety, weakness and exhaustion. The more frequent the indulgence the stronger will grow the power of habit and of passion and the greater will become the abnormal craving. It is the same with all other appetite and passions. The more frequently they are indulged, the stronger they grow, until
they attain complete control and develop into destructive habit

A free and confidential understanding in regard to these matters between those who contemplate matrimony would go far to prevent marital misery. A great deal of unhappiness arises from the fact that mates in the matrimonial union often labor under misapprehensions concerning the attitude of each toward the sex relation, and are prevented by excessive sensitiveness and delicacy from frankly discussing it. (For further discussion of this subject, see page 390, Volume I.)

There is no problem of married life that needs more thorough mutual consideration and understanding than this one. Lack of it accounts for a great deal of "incompatibility," loss of love, revulsion, hatred, and the final tragedy in the divorce court.

Among animals, no female allows intercourse after conception. In this respect as in many others, man has sunk below the natural standards of the animals. No greater crime can be committed against the woman and the unborn life.

It is a sad commentary on our system of education, scholastic as well as religious, that our young people are not instructed before and after marriage in these all important laws of Nature. To do this should be the province of the priest who unites them in marriage, or of the family physician, if the parents have failed in their duty.

It is well known (notwithstanding the denials of medical skeptics) that the unborn infant may be "marked" by transitory impressions, especially by strong emotions; that even insignificant parental characteristics are reproduced in the offspring. Is it any wonder, then, that the most powerful of human emotions should leave its impress on the growing brain and sex centers of the fetus, causing abnormal and precocious sex consciousness?

All too often is sex perversion born and bred in bone and flesh, before the child sees the light of day. The mother cannot be blamed for this "slaughter of the innocents"; she has not been instructed on the subject. Though she intuitively senses the horror of it, she submits, in order to maintain her hold upon the man—and many a life is thus cursed before it is born. The fault lies primarily with those of the medical profession who teach our young men that the free indulgence of sexual passion is not only legitimate, but a necessity to manly vigor.

This dictum of pseudo-science is almost universally concurred in by spiritual guardians. **No greater lie was ever promulgated from the blackest abyss of Hades.** If our young men were taught that greater happiness is to be attained by the exchange of tender affection than by the indulgence of the coarser animal appetites, that the creative forces thus preserved develop and strengthen their own finest capacities
of body, mind or soul, they would wisely and chivalrously protect mother and child, at the same time conserving their own physical and moral integrity.

In no other way is it possible to call forth the deepest gratitude and unfailing esteem of a true woman. Many a man whom we have thus advised has become a lifelong friend in consequence.

3. Limitation of Offspring. I believe that the unlimited production of offspring, encouraged in some quarters for swelling the ranks of religious bodies or for increasing tax paying and cannon-fodder material, is a misfortune, both to the family and to society. Limitation of offspring, in accordance with the means and circumstances of the parents, is not only justified but should be encouraged. In any case, the production of offspring entails great responsibility upon the parents and if they cannot properly comply with the needs and rights of their children, they fail in their responsibility and duty.

Any method, however, which interrupts intercourse or prevents conception in an artificial way, is absolutely to be condemned, because this has very harmful and positively destructive effects upon the physical, nervous and mental organism of those who thus try to cheat nature by the suppression of a natural process. In our professional work we frequently meet the victims of such pernicious practices. The ordinary contrivances for prevention make of intercourse something akin to masturbation. This is also true of intercourse without orgasm which is strongly advocated under various guises. The use of poisonous antiseptics and germ killers in warm water douches is not essential for prevention, and is highly injurious. These chemicals have a tendency to poison the sexual organs and to produce in time atrophy, many kinds of female disorders, and tumors. Undoubtedly the greater number of so called female troubles and malignant tumors in later life are caused by curetments, antiseptic douches and the use of poisonous drugs, for producing abortion. The only legitimate methods of birth control are abstinence or common cleanliness.

There is nothing more conducive to the physical, mental and spiritual health and development of a woman than childbearing and child rearing in harmony with Nature's laws, as outlined in these volumes. Under favorable conditions it is not a thing to be dreaded, but to be looked upon as the greatest of blessings and opportunities in the life of a woman. Natural philosophy and practice takes these problems of progeneration, childbearing and childrearing out of the domain of uncertainty and haphazard management with its dire consequences, and makes eugenics the most exact of all sciences and the sublimest and most enjoyable of all the arts.

4. Determination of Sex. Numerous theories have been advanced concerning this interesting subject. Many attempts have been made to wrest from Nature the secret of sex
determination and numerous more or less ingenious methods have been recommended for sex control.

I know of one method only which seems to have a rational basis and which has proved of practical value. Observations seem to prove that the right ovary liberates male ova only, while the left ovary discharges female ova. The two ovaries discharge ova only at alternate menstruations.

With this data at hand, it is possible to determine the sex of a child after one birth has taken place. Suppose the first child was a boy. By consulting our pregnancy table (page 377) we can determine when the last menstrual discharge took place. This menstruation liberated a male ovum; the next menstruation would liberate a female ovum, the next a male, etc.

Thus, using the last menstruation period before the last conception as a fixed point, it would be possible, figuring from period to period, to determine the sex nature of the ovum to be discharged at each following menstrual period. Account is taken of all regular periods during the time menstruation is suspended in pregnancy. Thus, conception may be timed in such a way as to impregnate at will a male or female ovum.

This solves in a simple, rational manner another of Nature's riddles, namely, the reason for the practically equal division of the sexes.

SECTION XXXIV

Prenatal Influence

There exists just as much diversity of opinion among scientists concerning the reality of prenatal influence as about race heredity, use heredity, disease heredity and many other mooted problems of science and philosophy, which we shall study in Vol. IV of this series. In the following I shall present and examine impartially the various theories and opinions concerning prenatal influence; then we shall be better prepared to draw our own conclusions.

1. Medical Science Denies Prenatal Influence. Medical men, as usual cocksure of the correctness of their theories and hypotheses based on the "latest discoveries", deny and ridicule the possibility of prenatal influence, and relegate it to the rubbish heap of popular superstitions. They base their judgment on the fact that no nerves pass from the body of the mother through the umbilical cord into the growing fetus in the placenta, which forms the soft protecting nest of the new life within the womb. They claim that since no direct nerve connection exists between the two, mental and emotional vibrations cannot be transmitted from the brain of the mother to the brain and nervous organism of the fetus.
Are there no other means of communication between the mind of the mother and the brain of the unborn!

In the volume dealing with Eugenics we shall learn how universal intelligence and creative will become individual intelligence and personal will.

Cosmic vibrations do not flow into the gray matter of the human brain over coarse physical nerve tracts. They come over the psychical wireless which connects the human soul with the world Soul, the individual intelligence with the universal or cosmic intelligence the human will with the divine will.

Since, as proved by modern brain and nerve anatomy, immaterial cosmic intelligence and "power to will" fashion the brain of the mother into physical material centers for the expression of human intellectual faculties, capacities and powers, why cannot these cosmic vibrations act in like manner over the psychic wireless through the soul and mind of the mother on the brain and nervous system of the fetal organism?*

These epoch making discoveries and revelations of modern brain anatomy are explained in Vol. IV of this Series, Natural Eugenics—Man Building on the Physical, Mental and Moral Planes.

Why should the wireless, which transmits impulses of intuitive intelligence from the great source of all intelligence and creative energy into the soul of the mother, cease to operate at that point, and fail to transmit its message to the brain and nervous system of the fetus which is most intimately related and connected with the organism of the mother?

What about the phenomena of hypnotism? Absolute control of the subject's mind, through the intelligence and will of the hypnotist does not depend upon the existence of an umbilical cord and physical nerve connection between the two. The hypnotist, by silent command, may call his subject from a distance, far beyond the reach of his voice.

People telepathically attuned may communicate in like manner, spontaneously, or by conscious intent. Why then should we doubt the possibility of vibratory correspondence between the mental and emotional conditions of the mother and the plastic nervous organism in process of development within her womb?

If a complexity of sound can impress itself permanently upon the wax cylinder of a phonograph, or what is still more marvelous, if the photographic rays of passing scenes can be fixed and retained in the picture film, why should it be impossible for the mental and emotional vibrations of the mother to impress and modulate the molecular and cellular constituents of the fetal brain and nervous organism?
I have compared this creative power of the mother mind to the process of electrotyping. As the particles of metal in suspension in the fluid adhere to the spoon that is to be coated with silver, so the atoms and molecules in the gray matter of the brain of the fetus group themselves in harmony with the thought forms and emotional vibrations of the mind and soul of the mother. While this mental and psychical electrotyping takes place automatically, the mother's brain and nerve molding power can be greatly strengthened and intensified by the conscious and voluntary operation of the psychical wireless that establishes vibratory oneness between her and the human entity in process of development within her own body.

Thus it is revealed how a brain prenatally refined, organized and fashioned may endow the nascent individuality with certain aptitudes and talents along established paths of cerebration. There surely will be less resistance along such lines of physical, mental and moral endeavor than along other lines not prenatally influenced and molded. Therefore I strongly advise mothers, pregnant with new life holding marvelous possibilities for good or evil, not to be influenced by the superficial reasoning of materialistic science, but to follow the sacred intuition and impulse of their own creative genius in this, the most holy function of their being. Every normally constituted mother is intuitively aware of this wonderful power, and is willing and anxious to exercise it when her consciousness has been aroused to the great possibilities and responsibilities which the divine privilege of motherhood confers upon her.

It is natural for us to admire a great artist who portrays the human form, true to life, on the painted canvas, or who fashions it from inanimate stone, metal or marble; how much more grand and godlike is the creative power of truly mated parents whose privilege it is to bring into the world, and to fashion according to their highest ideals, a human being endowed with life and intelligence, with the infinite possibilities of a new center of creative activity.

Yet many mothers, totally ignorant of their divine creative privileges and possibilities, victims of physically and morally degrading marriage relations, and often filled with secret aversion or open hatred for their marital companions, pass unwillingly through pregnancy and not infrequently seek to destroy the new life. When the unfortunate victim of such marital incompatibility, conceived in passion and developing under the worst possible influences of mental and emotional discord, comes to arouse the maternal instincts of affection and devotion, then fear, anxiety and worry, like a continual nightmare, haunt the unhappy mind of the mother and impress their discordant vibrations upon the sensitive films of infant consciousness.

Compare this condition of fear, apprehension and gloom in the mind and soul of an unhappy and unwilling mother, with the joyful and ecstatic state of mind of a mother conscious of
the creative power of her intelligent will, who, from the time of mating and procreation, with accurate prescience prepares the most favorable conditions, astrologically, prenatally and postnatally for the finest development of the physical, mental and moral characteristics of the future world citizen.

The loftiest exaltation of a creative genius working in dead clay and cold marble cannot approach the ecstasy of a mother who has acquired a knowledge of the great laws which make possible the development of a perfect human being, the embryo of a master, an angel, a being destined to be godlike in its faculties, capacities and powers!

In place of fear and anguish of soul, what joy to the mother who knows that it lies within her power to prevent disease and degeneracy in her offspring; that the development of the child depends solely upon her own intelligent effort! Nothing is left to accident. Child bearing becomes an exact science, the most beautiful and inspiring of all arts and professions. Under such conditions motherhood, instead of being the greatest of hazards and hardships, becomes a divine privilege and the highest achievement of human existence and endeavor. It falls short only of the creative work of the great Universal Intelligence whose instrument of creation is the mother.

2. An Example from History. Let us consider the oft-quoted example of Napoleon Bonaparte. His mother, Lutitia Bonaparte, while pregnant with the future military genius, accompanied her husband on a military expedition, sharing with him the hardships and excitement of camp life, and the marches and battles of a military campaign. If there be nothing in prenatal influence, is it not singular that Napoleon should have become one of the greatest military geniuses of all ages, while not one of his many brothers ever exhibited enough military ability to make an efficient corporal? What was it that favored or determined the birth of the great military prodigy under these circumstances? The ancestors of Napoleon's father were not professional soldiers, nor was the father especially interested in military matters before the conception of his gifted offspring.

The dominant influences, therefore, must have operated through the singular occupation and surroundings of the mother during this particular pregnancy.

Many similar striking examples have been cited in works on prenatal influence. I myself might add many convincing proofs from an extensive experience in medical practice; but time and space do not permit. Contributory evidence may be secured from many excellent works dealing with this vital problem in human life. I may be permitted to say that use heredity and prenatal influence are distinctly manifest in the physical and mental characteristics of our three children who were born at intervals of seven and five years. Each one of them clearly mirrors in his or her physical, mental and emotional peculiarities the predominant mental tendencies, occupation and surroundings of the parents during the
respective prenatal periods. Similar manifestations of prenatal influence may be observed in almost any family.

3. Birthmarks. Medical men of late deny also the possibility of "marking" the offspring by sudden fear or shock on the part of the mother during pregnancy. Incidents of this kind, however, are of such common occurrence that it is a waste of time to refute these flippant denials.

There are good reasons for believing that such marking is more likely to occur during the periods when the menstrual flow should take place, but is suspended.

It may be argued that to mention the possibility of marking to a pregnant woman will greatly increase the probability of electrotyping violent emotions upon her offspring; in other words, that the fear of the thing will help to materialize it. This may be true to a certain extent, but we must remember that sudden shock through fear or disgust may cause the mischief anyway, whether or not the expectant mother is aware of the possibility. Understanding a danger and being prepared for it seems the best protection. The pregnant woman should study carefully section XXX, dealing with mental and emotional causes of nervous diseases, and should learn to relax to any sudden surprise and thus neutralize unpleasant and fear arousing impressions. Self-control is the royal remedy and the key to mastership.

4. Physical Influence. Now that we have studied some of the more important hereditary mental and psychical prenatal and postnatal influences, let us see how the physical condition of the mother's organism influences the brain and nerve matter of the fetus in its last stages of development, and after birth.

Materialistic science teaches that brain matter exudes thoughts and feelings, as the liver excretes bile, or the stomach pepsin. Natural science proves that mind is superior to matter, that the new born ego, by the power of intelligent volition, must fashion in the gray matter of the brain the molecular groupings or centers for the expression of intellectual and emotional activities, such as language, music, numbers, scientific and philosophic speculation.

This means that active cerebration and brain molding do not begin until after birth. But it stands to reason that the work of the nascent intelligence may be greatly facilitated or impeded by the physical condition of the brain. It is reasonable to assume that intellectual and emotional vibrations will more easily shape the gray matter of the brain into new configurations when it has been prenatally refined, organized and developed along certain lines of cerebration by use heredity and by constructive prenatal influences.

There exists a remarkable similarity between the brain molding and memory building activities of the intelligent ego and the making of phonographic records and moving picture
films. Lifelike impressions of sounds and passing scenes can be made upon the phonographic and photographic mediums only when wax and film are in a highly refined and plastic condition. When impure of substance and coarse of texture they are not sensitive and plastic enough to register and retain the subtle and highly complex vibrations of sounds and passing scenes. In order to receive and register a great variety and complexity of sounds, the wax on the phonograph cylinder must possess a certain degree of refinement, softness and plasticity. If it is too hard and coarse it registers the loud and coarse sounds only. Such a record cylinder, exposed to a beautiful symphony executed by a great orchestra, would register and reproduce only the shrill cries of the trumpet, the rattle of the snare drum and the booming of the big horns and bass drums. The softer sounds of string, wood and wind instruments and finer shadings of tone and rhythm would be lost. With increasing refinement and plasticity, more subtle and delicate sound vibrations will be retained and reproduced.

In like manner the sensitive gray matter of the cortex of the brain must be in a pure and plastic condition in order to receive and register the impressions and impulses coming through the sensory organs, the psychic intuition and the intellectual and emotional activities of the mind. Anything in the way of physical impurity or foreign matter that tends to clog the brain, or to feed it with waste and morbid materials, or with corroding poisons, will lessen the atomic and molecular motility of brain and nerve matter, and will interfere with, or impede, the groupings and subtle transformations involved in the fashioning of brain centers through mental and emotional influences.

If the nutrient blood which feeds the brain substance of the fetus be saturated with CO₂, the benumbing, paralyzing carbon-dioxide, with clogging uric acid or the destructive acids of phosphorus and sulfur, the gray matter cannot, respond to the subtle and complex impressions and impulses from without and within.

The purity or impurity of the plastic matrix of the cortex depends upon the materials absorbed from food and drink. If these are so constituted as to create in the system excessive amounts of clogging and corroding substances, then these food and drink poisons will have a benumbing and deteriorating effect upon the sensitive gray matter of the brain, as well as upon the coarser tissues in the joints, muscles and vital organs. There is a rheumatism of the mind as well as of the joints.

A brain asphyxiated and clogged with pathogenic materials cannot be alert and active; it is too dull and lazy to think; it would much rather sleep than work; it is incapable of doing its best when its tiny blood and lymph vessels are obstructed with waste and morbid deposits which prevent the oxygenation and drainage of its delicately organized cellular tissues.
This, of course, is true postnatally as well as prenatally. A brain originally capable of the highest and finest achievements of the human mind may become utterly worthless, and may degenerate into idiocy through food, drink and drug poisoning.

Medical men tell mothers they need not worry over prenatal feeding, because the placenta, the vascular bag which forms the nest of the new life, acts as a filter which purifies the blood before it reaches the fetus. Common sense and every day experience tell another story. Even the best in the blood of many mothers is bad enough to serve as food for the new life.

The placenta does not filter out of the blood of the mother all food, disease and drug poisons. This is proved by the wretched condition of many infants, suffering from malnutrition, anemia and rachitis, after delivery. If the vital fluids of the mother are deficient in the mineral elements, or in other important nutritive substances, how can they deliver them to the fetus?

Occurrences like the following, quite common in our institutional practice, prove positively that the placenta is not a perfect filter for systemic poisons and for disease taints circulating in the blood of the mother.

One of the most pitiable cases of eczema in a little child less than one year old we traced to the fact that the mother, during her first year of marriage, had traveled with her husband through Eastern European and Asiatic countries, and during her pregnancy had been vaccinated five times while passing through localities where smallpox was prevalent. Both she and her husband had always enjoyed perfect health. The family record was excellent as far as traceable; still the body of the infant soon after birth, was covered with open bleeding sores, presenting a revolting sight. We could find no explanation for this strange phenomenon other than the many vaccinations during pregnancy. These had contaminated the blood of the mother, and through her the body of the fetus, with a filthy scrofulous taint.

The baby suffered terribly. For many months it slept but little, because of the excruciating pains. The eczematous eruptions were of a very stubborn nature; they broke forth again and again. Finally, however, after eighteen months of natural treatment, we succeeded in purifying the little body of the horrible infection. The child is now a little over three years old, in perfect health, and during the last twelve months has shown no signs of the morbid taint.

Under another section I shall describe the influence of food upon character and sex life.

To recapitulate: Purity, plasticity and motility of the highly refined and sensitive materials which make up the gray matter of the brain depend upon pure food, plenty of fresh air and exercise, and upon all other natural methods of living.
SECTION XXXV

Conception and Pregnancy

1. Conception takes place whenever the male spermatozoon joins the female ovum (egg) within the woman's womb. Normally the female organism liberates from its ovaries but one ovum each month, usually during menstruation, while the male discharges millions of spermatozoa at each orgasm.

Conception does not always follow copulation. The ovum remains in the womb and is capable of impregnation for about five days after menstruation. The spermatozoon on entering the womb may meet an ovum which has been discharged at a previous menstruation, or it may remain alive in the womb for a number of days and finally come in contact with a newly discharged ovum at the following menstruation.

The spermatozoon retains its ability to impregnate the ovum for from ten to fifteen days after its discharge into the womb. When the male and female germs merge into one another, conception or impregnation takes place. As soon as this has happened, the impregnated ovum becomes attached to the inner lining or mucous membrane of the womb and begins its new life as an embryo. The period comprising the time from the impregnation of the ovum until the beginning of labor or childbirth is called pregnancy.

The table of pregnancy on page 377 indicates the probable date of normal termination of a pregnancy, calculated from the last menstruation.

2. Exercise During Pregnancy. Unfortunately a great many expectant mothers labor under the idea that they must rest and be relieved from work and exercise. This of course is a great mistake. Light housework is good exercise. There is nothing more harmful during pregnancy than nursing "that tired feeling" by lounging idly about the house and coddling one's real or imaginary aches and troubles.

Of great benefit to the pregnant woman are all outdoor sports such as tennis, golf and other games which require vigorous exercise without straining or overworking the body. The great benefit of walking and other outdoor exercises, aside from their general invigorating effects, lies in the strengthening of the abdominal muscles and ligaments, which at delivery will greatly facilitate expulsion of the fetus.

The walk should be brisk and rhythmical, body erect, head thrown back, chest forward; the breathing at the same time should be deep and regular. These walks should be continued as long as time and endurance permit. Nothing, of course,
must be pushed to the point of exhaustion. One good long walk every day is necessary; two are better.

We all understand the necessity for a plentiful supply of oxygen under ordinary conditions, and especially in time of illness. During pregnancy the demand for oxygen, as well as for mineral salts, is doubled or trebled on account of the needs of the rapidly developing organism in the womb of the mother.

These extra demands for oxygen and ozone must be supplied by systematic deep breathing, cold bathing, outdoor walks, etc. If circumstances do not permit the taking of outdoor exercise, deep breathing should be practiced as often as feasible, at the open window.

Next in importance among gymnastic exercises is the internal massage described under section XXI, No.16.

Those exercises are especially valuable which bring into play the abdominal muscles and the muscles and ligaments of the genital organs.

3. Clothing. Clothing and the manner of wearing it profoundly influences the normal or abnormal development of the fetus, the health of the mother, labor and delivery.

At no time should the waistline be constricted by a corset or even by the ordinary skirt band. All clothing should be as loose and light as possible—one-piece under and outer garments, with the weight suspended from the shoulders, are best. If skirts are worn they should be fastened to skeleton waists of some thin cotton material. The close, heavy texture of the material from which the corset or so called "reform waist" is made is injurious because it interferes with skin elimination.

Even the slightest constriction of the waist line interferes with the free circulation and the normal blood supply to the abdominal organs, which is of especial importance in pregnancy; it also hinders the free expansion and movement of the uterus during the various stages of pregnancy.

Within the waistline are located a dozen or more important vital organs of the body. Any sort of constriction compresses these organs and pushes them out of their normal position. While this is extremely injurious to the body of a woman under ordinary conditions, it is doubly so to the pregnant mother and to the rapidly growing fetus. Undoubtedly many deformities and monstrosities are produced by unnatural constriction of the blood vessels and vital organs in the abdomen and pelvis of the pregnant woman.

If due attention is paid to the foregoing influences, labor and delivery will be brief and easy. This we have proved in hundreds of cases which have come under our management. The reason why women of civilized countries spend many
hours and sometimes days in dreadful agony of childbirth while those of primitive or savage races, as we call them, produce their young easily and painlessly as the animals do, is that primitive women live more simple and natural lives, while "civilized" mothers violate practically every law of Nature in their daily habits of living.

Civilization unfortunately stands in many respects for that which is artificial, unnatural and therefore productive of disease and suffering in all domains of life, not only as regards physical health, but social and political health as well.

SECTION XXXVI

Danger Signs During Pregnancy

1. Dropsical Swelling. Swelling of the limbs and distention of the veins of the legs during pregnancy may be caused by a tendency towards varicosity, intensified by obstruction of the circulation due to the enlarged uterus. Such a condition requires, aside from the natural regimen, careful and competent treatment.

Swelling of the limbs or other parts of the body may also be caused by incipient or advanced Bright's disease. The urine should be examined from time to time, especially if there is a swelling of the feet and ankles, or if there are dropsical symptoms in other parts of the body.

Such dangerous conditions are usually brought about through the excessive intake of starchy and protein foods which overwork the liver and kidneys and cause pathogenic dogging of the capillary circulation. This may result in uremia attended by violent and sometimes fatal Convulsions.

2. Uremia is the result of retention in the system of waste materials and poisons that should be eliminated through the kidneys and skin. Medical treatment for such conditions, aside from the administration of stimulating drags, consists in hot bathing with the idea of opening the pores of the skin.

We understand that all hot water treatment gives only temporary relief and is followed by greater enervation and inactivity of the skin. The best water treatment for systemic poisoning of any kind consists in the application of wet packs followed by cold ablutions as described in section XV.

The addition to the packs, dry friction rubs, air bath, good massage and neurotherapy treatment will aid in restoring the normal activity of skin, bowels and kidneys.

Whenever the urine contains sugar or albumen, fasting, alternating with raw food diet, is indicated. Suitable regimens are outlined in sections X, XI.
The giving of heavy food to the mother with the idea of increasing the flow of milk is all-wrong. We have found in all cases that the diet outlined in section X will produce a more copious flow of rich milk than lie "nourishing" meat diet. The best remedy for a scanty flow of milk is slow and thorough mastication of a few spoonfuls of raw crushed wheat every day.

3. Morning Sickness. One of the common disorders experienced during pregnancy is that known as Morning Sickness. One suffering from this ailment, though following a natural diet, should sip a cup of hot postum while remaining in bed. If this does not have the desired effect and if the patient has not been accustomed to drinking coffee, half a cup of black coffee with a few drops of lemon juice will quiet the irritated nerves. It is necessary after taking the hot drink to remain in bed for at least thirty minutes. It is understood that this is only an emergency measure. If continued, it will lose its good effect and work injury.

SECTION XXXVII

Labor and Delivery

At about forty weeks, exactly nine solar months, from the period of conception the fetus reaches full maturity, and labor begins. Labor is divided into three stages. During the first stage the neck of the womb becomes slowly and gradually distended and the orifice of the womb opens widely. When this has taken place, the fetal membranes burst and the amniotic liquid surrounding the fetus escapes.

During the second stage the fetus emerges from the womb.

After expulsion of the fetus, the placenta is expelled from the uterine cavity. This constitutes the third stage of labor.

The first stage usually begins with more or less radiating pains in the abdomen, accompanied by dull pain in the small of the back and a drawing pain in the limbs. Sometimes women with the first baby feel these pains weeks in advance of the actual commencement of labor. At first they occur at long intervals and are of short duration, but gradually become more prolonged and more frequent. The pains are due to a cramp-like contraction of the muscular apparatus of the uterus forcing its contents downward.

Under this pressure from above, the neck and mouth of the uterus distend to their limits, and the walls become thinner and thinner. First the inner, then the outer orifice of the neck of the womb opens and the fetal membranes protrude and finally rupture, allowing the amniotic fluid to escape. Shortly after this the part of the fetus nearest the orifice, normally the
head, makes its appearance. At the present time the average duration of the first stage of labor is six hours, but it may last twenty-four hours or longer, depending upon the plasticity and elasticity of the bony structures of mother and infant, the rigidity of the cervix, and the vigor or lack of vigor of the muscular apparatus of the uterus.

While the foregoing is true of the average delivery under ordinary ways of living, we find that after the enforcement of a natural regimen of living during and, better still, before pregnancy, the entire period of labor and delivery does not cover more than half an hour, or at the utmost from one to two hours. Even the disadvantages of slight build and smallness of pelvis can be overcome by the natural regimen outlined in section X. When our youngest child was born, the mother gave the first sign of pain at about midnight. I rose from bed instantly, but had not time to finish clothing when the membranes broke. Within twenty minutes after the commencement of labor the infant was resting in my hands.

The wife of a prominent lawyer in a western city had experienced three difficult deliveries. Each time surgical instruments had to be used and she had suffered untold agonies lasting from 24 to 36 hours. When she became pregnant the fourth time the most prominent physicians in her home city assured husband and wife that it was not safe for her to go through another delivery, that the womb was in worse condition than ever before therefore they recommended surgical removal. For conscientious reasons, however, the husband and wife did not follow the advice of the doctors, but decided to try natural methods of treatment.

The lady placed herself under our care during the fifth month of pregnancy. From that time on she followed strictly the natural regimen of living and received daily the usual hydropathic and manipulative treatments. This was continued until a few weeks before delivery. In this case the baby was born within an hour from the first contraction, and the mother of the patient, who was in an adjoining room, had not heard a sound. Many similar experiences refute the idea that it is unsafe and injurious for pregnant women to undergo the ordinary methods of natural treatment, such as hydropathic sprays, sitz baths, massage, Swedish movement and other forms of manipulation.

1. Preparation for Delivery. The diet during the last week before the beginning of labor should be very light, consisting mostly of fruits and vegetables. From the commencement of labor no food at all should be given, until at least twenty-four hours after delivery; a three-day fast is better.

In addition to a competent physician, a nurse or midwife should be engaged. If a good neurotherapist, who has had sufficient experience in obstetrical work, can be procured, he should be preferred, because he can assist delivery and make it much easier by manipulative treatment.
The nurse will make the necessary preparations and provide the various supplies needed in labor. With the first sign of approaching labor, the physician in charge should be summoned. A rectal enema of one pint or more of warm salt water (See. XVIII, No.4) should be administered. The woman should be given a vigorous cold rub and her genitals thoroughly cleansed. She may then remain on her feet and walk about, comfortably dressed, until actual labor commences.

2. No Anesthetics. The attending physician should not be impatient to hasten delivery with drugs or instruments. The use of anesthetics should be avoided insofar as this is possible. They should be employed only when absolutely necessary—that is, when excessive pain must be allayed or when surgical delivery is unavoidable.

3. Breaking of Water Bag. When the bag of water is about ready to break, the patient is placed in bed. Premature discharge of the amniotic fluid must be guarded against. An escape of the liquid at an early stage means difficult and prolonged labor, commonly known as "dry labor". Usually the membranes burst when the orifice is fully dilated. A large sponge is held in readiness to catch the out-flowing liquid.

3 a. Umbilical Cord. When the infant has been delivered, the umbilical cord should not be severed at once. Plenty of time should be allowed for the blood to transfuse itself from the body of the mother to that of the child. This is important. If the connection is severed too soon, the child begins life in an anemic condition.

The newborn baby usually greets the world with a lusty cry. It should be placed on its right side with its face turned away from the mother, care being taken that the cord is not stretched tight. As soon as the cord stops pulsating, plenty of time being allowed for blood transfusion, it is tied about two inches away from the baby's abdomen and cut a little above the ligature. The baby is now wrapped in a warm blanket and put in its crib.

4. After Delivery. Immediately after the baby is born, the nurse or attending physician gently compresses the abdomen and womb of the mother, kneading and rubbing it occasionally in order to secure complete contraction and thus prevent hemorrhage. After delivery the mother enjoys a period of rest and recuperation which usually lasts for about half an hour.

5. Afterbirth. Meanwhile the placenta becomes detached, and when the pains set in again a few contractions usually suffice to expel it with all the membranes.

The attending physician must make sure that none of it is left in the body, since this might result in putrefaction of the remains and blood poisoning. The woman's genitals should be washed with clean sterilized water.
The exhausted woman should now enjoy a deep, wholesome sleep and awaken from it in a few hours refreshed and strengthened.

In the foregoing I have not gone into the details of obstetrics and of technical management because this must be left to a competent obstetrician. I have called attention only to those points which are of special importance from the viewpoint of Natural Therapeutics and to the differences in treatment between the conventional and natural methods.

6. The Lying-In Period. The lying-in period varies from five to twelve days, according to the constitution of the mother and the care that she has taken during pregnancy. The greatest danger of the lying-in period is puerperal sepsis or blood poisoning. This condition is the result of infection occurring during labor, or it may result from the retention of parts of the placenta.

The only way to prevent this is by observing the most scrupulous cleanliness during the entire process of childbirth and during the lying-in period. When blood poisoning has developed it must be treated the same as all other acute inflammatory diseases (see section IX).

7. Care of the Newborn. The child should begin to breathe immediately after the cord is cut. If it fails to do this, the physician should lift the baby by its feet to facilitate the escape of mucous from the trachea and throat. If necessary the mucous must be removed from the throat by the insertion of the little finger, or by means of a tiny stick covered with gauze.

Breathing may be accelerated effectively by a few sharp taps on shoulders and buttocks. If this fails to bring the desired result, artificial respiration must be resorted to at once. The attendant grasps the child by its shoulders, its head resting between his palms and the two index fingers being hooked under the child's armpits. It is now swung between the physician's legs and lifted high above his head so as to be turned upside down. This is repeated from fifteen to twenty times, after which it is placed in a basin containing a few inches of warm water. Its body should then be rubbed briskly with cold water.

Father Kneipp used to take the newborn babe by the nape of the neck and the feet and submerge it quickly in cold water. This, a few times repeated, is probably the quickest way of resuscitating an asphyxiated baby.

In order to soften the cheesy deposit which frequently covers the body of the newborn, it is well to rub the skin with warm olive oil. After the greasy covering has sufficiently softened it may be removed with bits of gauze. This is followed by a cleansing bath with warm water and castile soap.
After the warm cleansing bath, the little body should be quickly rubbed down with cold water, wrapped in a soft, warm blanket and laid away to sleep until it wakens of its own accord. A normal baby should sleep for about twelve hours, and must not be disturbed to force food on it before it is ready to take it.

8. Bathing. From the first day, the baby must have a morning and evening bath. This consists, as before described, in a quick, cleansing bath of warm water and castile soap, followed immediately by a brisk cold rub. In the course of a few weeks the baby can be placed, for the cleansing bath, in a small bathtub containing a few inches of warm water. Immediately after the cleansing bath the warm water is replaced by cold water. This is taken up in the hollow of the hand and briskly applied to the little body. In this fashion the child, within a few months time, will enjoy its cold rub just as much as an adult. I have seen several such nature cure babies, but a few months old, object most vigorously to a warm bath. The cold rub is the best preventive of chilling; but care must be taken that the temperature of the room where the bath is given is not below 70 deg.

The olive oil bath or rub, often recommended for premature babies or infants suffering from malnutrition, is very injurious, because it occludes the pores of the skin and prevents the elimination of poisonous gases and other morbid materials from the body. The skin is not an organ of digestion. Olive oil, like all other foods, must enter the body through the alimentary canal where, under the action of digestive ferment, it is broken down into its component elements which are then assimilated through the intestinal membranes. Oil absorbed through the skin is not digested, and it circulates in the body as foreign matter which in this state cannot be assimilated and utilized in the system.

9. Powdering after the bath is fully as injurious as the rubbing with oils or massage creams. Powders and creams tend to clog the pores, and most of them contain poisonous antiseptics which lower the vitality of the skin and prevent or suppress elimination in the form of skin eruptions, eczemas, etc. For chafing use nothing but cold water. In case the chafing should become unusually severe and painful, through neglect by the caretaker, a soothing and healing lotion composed of one part lemon juice to two parts olive oil, may be applied a few times, until the irritation is under control.

10. Air Baths. Next to cold water, there is nothing that will invigorate baby's skin and nervous system as will the air and sun bath. If the season will not allow the outdoor air bath, the baby should be allowed to lie nude several times a day, for thirty minutes or more, in a warm, well ventilated and sunny room.

11. Constipation. Glycerin and suppositories should never be used; neither laxatives nor cathartics. Oat extract and cooling sitz baths will produce natural movements.
12. **Diarrhea** is a form of morbid elimination, and must never be suppressed by drugs. If it is habitual, bailey or wheat extract prepared in the same manner as oat extract, is a good remedy. If the diarrhea is persistent and of a violent nature, no food at all must be given, except water with dilute acid fruit juices, until the purging ceases. Even then plenty of time must be allowed for the rebuilding of the sloughed intestinal membranes.

13. **Bandages.** Until the umbilical cord dries up and falls off, it is necessary to cover the navel with a gauze compress dipped in olive oil. This is held in place by an abdominal bandage made of soft cotton material. These strips should not be hemmed, merely torn or cut. They should be drawn just snugly enough to hold the compress in place, but not tightly enough to interfere with circulation. The, navel must be cleansed and the compress renewed twice each day. After the umbilical cord has dropped off we no longer apply the abdominal bandage. This is contrary to common usage, but is the best practice. The abdominal bandage overheats the body and interferes with the free movement of the diaphragm and the circulation of the blood.

14. **Clothing.** The clothing of the infant should be loose and light and as simple as possible. Freedom of movement is very important; binding or pressure upon any part cannot help but interfere with the circulation, and otherwise produce injurious results. The clothes should be short, in order to allow the feet and legs free play. Light weight, porous cotton materials are best for both under and outer garments. A lightweight wool petticoat may be worn when absolutely necessary to provide sufficient protection for the baby. Cotton hose and bootees may be used, but under no circumstances should such articles be of wool, because it prevents free elimination from the skin. The baby's head should not be covered out of doors, except in severe weather. At no time should a veil be placed over the face, as it will cause the infant to reabsorb the poisonous exhalations from its own lungs. All clothing should be changed each day. No garment should be starched—such a practice is not only useless but harmful.

15. **Diapers** must be provided in sufficient number to allow thorough cleansing and drying. The wet diapers should be scalded in hot water and very thoroughly rinsed in several waters afterwards. They should then be dried in the open air and sunshine. Soiled diapers must be well washed and boiled. Washing powders, soda, ammonia and other chemicals should never be used. They have an extremely irritating effect upon the delicate skin of a baby. In order to save labor and to facilitate the cleansing of the diapers, small squares of clean old linen or muslin rags, or pieces of absorbent gauze, may be placed inside. These inserts will absorb all or most of the bowel movement and may then be burned. If the skin is irritated or chafed, the parts should be sponged off with clean cold water at each change, paying special attention to cleansing of the genitals. Oils or powders must not be used to soothe the sore places, because they clog the pores and
Interfere with natural elimination.

16. A wet nurse is to be preferred to artificial feeding. She should be thoroughly healthy, not over thirty years of age, of equitable temper, not excitable or nervous and her diet should be that prescribed for the mother.

17. Care of the Nipples. They should be thoroughly cleansed before and after nursing; not with carbolic acid, but with water and dilute lemon juice. The lemon juice tends also to harden the nipples. Treatment of the nipples may begin before the birth of the child.

18. Care of the Eyes. The baby's eyes, whether awake or asleep, should always be shielded from strong light, either sun or artificial, and from dust and wind. The eyes should be washed with cold water after every cleansing bath. If they show any tendency to weakness or disease, slight vibratory massage over the closed eyelids should be given after the cold eye bath.

19. Care of the Mouth. A healthy baby's mouth needs no cleaning before the arrival of teeth. As a matter of fact, the teeth of a perfectly healthy adult would not need cleaning any more than do those of an animal living in the freedom of nature. The saliva is a sterilizing fluid, under normal living, intended by Nature to keep the mouth clean and healthy. Cleansing of the mouth of an infant with the finger or with a cloth may injure its delicate membranes. If the mouth must be washed, in case of disease, a swab made by twisting a piece of sterilized absorbent cotton on the end of a smooth stick should be used. The swab should be dipped in warm boiled water, and the interior of the mouth washed thoroughly, the cotton then being burned.

20. Care of the Ears. The external ear should be cleansed with a soft rag or swab as before described. Never use a hard instrument inside the ear.

21. Care of the Nose. A baby's nose should be cleansed as a part of the daily toilet, in the same way as the ears. A swab may be made by twisting a, piece of gauze to a cone. As soon as the child becomes old enough, it should be taught to sniff up cold water through the nostrils and the nasal passages. This is the best way to keep the nasal membranes in a clean, healthy condition.

22. Care of the Genital Organs. The genital organs of both sexes must be kept scrupulously clean with as little handling as possible. The foreskin of the penis of the male baby should be drawn back at bathing time and the organ thoroughly cleansed, always finishing with cold water.

23. Phimosis. The treatment of phimosis is fully described under Sec. XXVIII, No.1.

24. How to Lift the Baby. The best way to lift a young
baby is to slip the left hand under the back beneath the shoulder, spreading out the fingers in such a way as to support the neck and head. Then lift the feet and legs with the right hand. Never lift an infant without first supporting the spine.

When a baby has grown strong enough to hold up its head and has gained considerable strength in the muscles of the back and neck, he may be lifted by grasping him with outspread fingers under the armpits; the body must be held firmly so that the entire strain does not come on the shoulders. A baby should never be lifted by the arms. This may dislocate the shoulder joints.

SECTION XXXVIII

Prenatal Feeding

1. Effects of Diet During Pregnancy. The problem of infant nutrition begins before birth. Prenatal feeding determines the physical start in life. On it depends not only the condition of the mother's health during pregnancy, but also the size and weight of the fetus, pliability of the bony structures, ease or difficulty of delivery, and the quality of the mother's milk.

    The fleshier and heavier the newborn infant, the prouder and happier are the parents and the doctor. Yet, excessive size and weight of the child constitute the most prominent cause of difficult and painful childbirth and frequent necessity for instrumental delivery.

    The biblical saying, "In sorrow thou shalt bring forth children"; has led many to believe that woman's dreadful suffering is a necessity, God ordained; but is not man's ignorance, rather than the cruelty of an avenging God, to blame?

    This latter view is confirmed by the fact that other mammalia literally cast their young, without pain or difficulty; and the labor pains of primitive mothers are insignificant, their delivery presenting little more difficulty than that of the lower animals. A squaw on the Western Plains stops a few hours by the wayside to deliver her papoose and then resumes her journey as though nothing had happened.

    Women among the European peasantry, who wear no corsets, live on black bread and vegetables, and have plenty of exercise in the fields and in the home to the last day of pregnancy, have their babies without help of midwife or physician and resume their usual routine of work within a few days after delivery.

    Thousands of mothers who have adopted natural ways of
living have learned to dispense with anesthetics and the surgeon's instruments; they now bring forth their offspring without excessive pain.

2. Results of Faulty Diet. It is significant that the offspring of the lower animals, at birth, consist of little more than skin and bones, while the newborn human is often abnormally large and fat. This is especially true of babies born of weak and anemic mothers. As before stated, excessive size and weight of the infant is not a matter for congratulation, but is a pathological condition. It indicates fatty degeneration of the fetus, due to the anemic watery condition of the blood of the mother, and the cause of this hydremia of mother and child lies in the faulty dietetic habits of the former.

The ordinary diet of American women consists almost entirely of meat, fish, fowl, potatoes, white bread, pastry, coffee, tea and refined white sugar. The few vegetable, which enter into the daily dietary are first deprived of their all important organic salts by faulty cooking; fruits are looked upon as luxuries and frequently are regarded as harmful

The anemic, watery condition of the blood of mother and child is not due to a lack of starchy, protein and fatty materials in food and blood, but to a deficiency of organic mineral elements. Neither is the anemic condition, as the regular school of medicine assumes, caused by lack of iron. Any ordinary food mixture, as well as the blood and milk of anemic mothers, usually contains a sufficient amount of iron. The actual cause of the anemia is a deficiency of other mineral elements.

As I have explained in Volume III of this Series, carbonic acid poisoning and the resulting sluggishness of the surface circulation, coldness of the extremities and congestion of the inner organs is not caused so much by a lack of the oxygen-carrying iron as by a deficiency of the carbonic acid neutralizing and eliminating sodium and magnesium.

If the blood is deficient in lime, phosphates, silicon and fluorine, rachitic conditions, softening of the bones, deformed spines and legs, and decay of the teeth, are inevitable results.

It is an easy matter to supply the daily needs of the organism for proteids, starches, fats and sugars; the difficulty lies in supplying a sufficient amount of the organic mineral elements.

The deficiency of sodium in human blood, Dr. Lahmann proved in the following table of comparative blood analyses. In a hundred parts of ash he found in the

| Blood of oxen | 12.41 to 31.90 |
| Blood of sheep | 13.33 |
| Blood of cows | 10.40 |
| Blood of hogs | 5.33 to 7.62 |
Blood of dogs | 2.02 to 5.78
Human blood | 2.03 to 6.27

The percentages of lime and of other positive mineral elements in the human blood are also much lower than in the blood of cows, oxen and sheep.

While the blood of cattle and sheep raised on pasture is very uniform in composition, hardly any two samples of human blood are alike. It is for this reason that Dr. Lahmann adopted cow's milk instead of human milk as the standard elementary food combination.

In the following table, he compares the percentages of minerals in the ash of cow's milk with the percentages of mineral elements in the ash of various other food materials.

A daily dietary consisting largely of meats, eggs, white bread, potatoes, peas and beans, though excessively rich in proteids, fats and starches, will, on account of its deficiency in sodium, lime and magnesium, inevitably result in carbonic acid poisoning, anemia, rachitis, premature decay of the teeth and a multitude of other acute and chronic ailments.

If, however, the daily dietary contains a liberal amount of green vegetables and fruits, a normal food mixture resembling that of cow's milk can easily be obtained. It must be remembered that fruits and vegetables are not only rich in the most important mineral salts, but that they are relatively poor in proteids and carbohydrates.

For this reason fruits and vegetables facilitate the establishment of an equilibrium between proteids and carbohydrates on the one hand and organic mineral salts on the other.

### 3. Excessive Fat Formation

We can now understand why the ordinary faulty diet of pregnant mothers causes anemia, softening of the bones, sluggish circulation, carbonic acid poisoning and fatty degeneration in mother and offspring.

Lack of sodium causes excessive accumulation of carbonic acid, and oxygen starvation. This results in defective
oxidation of food and waste materials; in other words, in fat formation.

Defective draft prevents the complete consumption of coal, and chokes the furnace with the products of imperfect combustion. Similarly, lack of oxygen in the tissues (due to carbonic acid poisoning) causes an incomplete combustion of food materials and waste products, resulting in fat formation and in the generation of poisonous byproducts.

Lack of sodium also prevents the neutralization and elimination of uric and other acids and ptomaines (pathogenic matter) which accumulate in the tissues, block the circulation and assist in the smothering of the vital processes.

In order to eliminate these pathogenic materials, there arises an abnormal craving for water—"the anemic thirst"—which is closely related to the thirst of fever patients and of diabetics. Excessive water drinking is encouraged by the popular "flushing" fad.

To make things worse, the anemic, for reasons before stated, usually suffers from weak heart action and sluggish circulation. This means defective elimination of water through the skin and kidneys, resulting in a watery (dropsical) condition of the tissues and fatty degeneration.

Not all anemic, carbonic-acid-poisoned mothers, however, develop a tendency to obesity. On the contrary, under certain constitutional conditions, they may become exceedingly lean, like the anemic, carbonic-acid-poisoned consumptive. Briefly stated, sluggish heart action and weak kidneys favor retention of carbonic acid and water in the tissues and thus make for fatty degeneration. Good circulation and normal activity of the kidneys may keep the system free from excess of water and carbonic acid, but excessive proteids in the diet may result in sulfuric and phosphoric acid poisoning. These destructive acids break down the tissues, rob them of their mineral constituents, and thus cause excessive loss of flesh and fat.

In both types of dysemia the blood of the pregnant mother is overloaded with poisonous gases, waste matter and the debris of broken-down tissues. The oxygen supply to the fetus is therefore very much impeded and we find that both fleshy and lean mothers produce babies of abnormal size and weight, ranging from eight to twelve pounds, while the normal weight of the newborn should not be more than six pounds.

4. Advantages of Natural Regimen. We know of many instances where mothers, after having given birth to heavy, fleshy babies, in subsequent births have reduced the weight of the new born to normal, and the pain of delivery to a minimum, by the adoption of a natural diet, plenty of exercise in the fresh air and systematic deep breathing.
The effects of a natural regimen are manifested in various other ways. The bony and muscular structures of mother and child are much more pliable and elastic, making parturition and delivery much easier. Pure blood, normal nutrition and abdominal exercises, walking and special gymnastics, greatly strengthen the abdominal and uterine muscles, thus facilitating expulsion of the fetus.

The morning cold rub, systematic deep breathing and general exercises, every day outdoor walks and right mental and emotional attitude are all of paramount importance in the regimen of pregnancy.

The Regimen for Wholesome Living, section I, is admirably adapted for all the needs of the pregnant mother.

SECTION XXXIX

Postnatal Feeding

Thanks to the educational influence of nature cure propaganda, a decided change for the better in baby feeding has taken place during the past ten years. Up to that time the "top cream mixture" was universally recommended by allopathic physicians and given to babies by trained nurses.

While in the meantime many physicians and nurses have adopted more natural methods, the "top cream mixture" is still too common and must be entirely abolished in order to safeguard the health of our little ones.

In the February, 1909, issue of the Nature Cure Magazine, I commented upon this subject as follows:

**1. Bottle-fed Babies.** Our food analyses disclose the interesting fact that the elementary composition of the ash of the milk of an animal is about the same as the composition of the ash of its body.

They also show that good cow's milk when normal comes closer to the requirements of the infant body than does inferior human milk.

Our tables of food analyses show that chemically the composition of cow's milk and of human milk is very much the same. Human milk contains a little less proteid and a little more sugar than cow's milk, and the latter is much richer in organic salts than the former. There is much more of the all-important sodium in cow's milk than in human milk and about twice as much calcium (lime) and iron (table p.100). This explains why rachitis is so common among babies, while never found among calves.

As we have learned, the elimination of poisonous acids
from the body depends on sodium. The building of the bony structures depends on lime; the oxygenation of the blood, on iron.

Many years of practical experience in the care of babies has convinced me that milk fresh from a healthy cow is greatly to be preferred, as nourishment for infants, to the impoverished milk of scrofulous mothers.* In this connection it is significant that one-half of all "civilized" mothers, thanks to unnatural food and drink, vaccination and poisonous drugs, are incapacitated for nursing their offspring.

* This may not be true in the future if our milk cows continue to be regularly subjected to tuberculin tests.

To one who has studied the comparative analyses of cow's milk and human milk, it is incomprehensible why the former, when given to infants, should be diluted and spoiled by large quantities of water, salt, soda and inorganic mineral lime (in the form of lime water).

This procedure, however, is still frequently recommended by physicians of the regular school. Undoubtedly, the great frequency of anemic and rachitic diseases, the darkening of the iris, appearance of scurf rim, and the signs of catarrhal conditions in stomach and bowels are caused by such unnatural feeding.

The following extracts are taken from an article entitled "Bottle-fed Babies", in the Ladies' Home Journal. It was written by Dr. Emelyn Lincoln Coolidge, of the Babies' hospital, New York. Thousands of mothers, on account of the high standing and excellent reputation of this family journal, undoubtedly have followed, without question or misgiving, the advice presented.

The formulas given below are for the average healthy baby, and are called "cream" or "top milk" mixtures.

"Food for the first month. With a spoon, or a tiny dipper which comes for this purpose, carefully skim off the top six ounces from a quart bottle of milk; to this add twenty-four ounces of water which has been boiled and cooled, and in which has been dissolved three teaspoonfuls of granulated or six of milk sugar; next add a pinch of bicarbonate of soda and a small pinch of salt; mix this all thoroughly, and pour enough for each feeding into ten separate bottle& Then cork the bottles family with cotton and either Pasteurize the milk or stand it on the ice.

"For the second month. Skim off six ounces of cream, then pour off three ounces of milk; add twenty-four ounces of water and the same amount of sugar, salt and soda as above; mix and bottle.

"For the third and fourth months. Cream, six ounces; milk, six Ounces; water, twelve ounces; barley or oatmeal gruel, twelve ounces; sugar, salt and soda as usual, etc.

Plain Milk Formulas

"Pour the entire quart of bottled milk out into a clean pitcher and then back into the bottle several times, thus thoroughly mixing the milk; then take:
"For the first month. Six ounces of milk, twenty-four ounces of barley-water, half a tablespoonful of granulated or one of milk sugar, a pinch of bicarbonate of soda; mix all well together and pour the proper number of ounces into separate bottles, and either Pasteurize or place on ice.

"For the second month. Nine ounces of milk, twenty-one ounces of barley-water, one tablespoonful of sugar, and a pinch of soda."

Physicians would never think of giving such advice as, this, if they were acquainted with natural dietetics founded on exact and complete analyses made by food chemists of the nature cure school.

I have already called attention to the fact that food chemistry, whether practiced in allopathic colleges, in great sanitariums or by vegetarian food reformers, deals with proteids, starches, fats and sugars only, and leaves entirely out of consideration the all important mineral elements or organic salts of potassium, sodium, iron, lime and magnesium.*

*This was true at the time this article was published in the Nature Cure Magazine.)

On these five positive mineral salts, as we have shown, depend all the important vital functions of the human organism, while proteids, starches, fats and sugars serve only as building and fuel material.

The digestion of the proteid and carbohydrate foods, as well as the elimination of the waste matter resulting there from, depends upon the positive organic mineral salts.

Study carefully these recipes for baby feeding, taken from the Ladies' Home Journal, and compare the mixtures with the analyses of cow's milk and human milk in the accompanying tables.

Let us consider the "top milk" mixture, prescribed for the first month. The cream rising to the top is almost pure fat. The all-important mineral elements plus the nourishing milk sugar and proteids remain in the skimmed milk, which is looked upon as worthless and fed to the pigs.

Our food analyses (see tables in Volume III, Cook Book) show that the ordinary brands of flour are almost devoid of mineral elements. Furthermore, one teaspoonful of barley to one pint of hot water does not mean much in food values. Where in these six ounces of cream (fat) and twenty-four ounces of barley water is baby to get the necessary amount of sugar for fuel material, of proteid for tissue-building, of lime for bone-building, of iron for oxygen-carrying, and of sodium, magnesium and potassium for the processes of elimination?

It seems that these deficiencies are intended to be overcome by baking soda, mineral table salt and the lime water, so generally prescribed by physicians. Many times I have demonstrated that inorganic mineral salts, with the possible exception of a little table salt, should not enter the animal or human organism, that these salts must first be organized,
made alive in the plant or animal cell, before they are wholesome food for animals or human beings. I have shown that, taken habitually in the mineral form, these salts accumulate in the human body, act as irritants and poisons and reveal their presence in the iris of the eye.

I fail to understand why the tender and sensitive organism of the newborn infant should be encumbered with inorganic minerals while cow's milk contains them in ideal form, made alive first in the grasses and grains, then still more highly organized and magnetized in the body of the animal.

It is bad enough to give mineral sodium, lime and table salt to an adult, but it is little short of criminal to give them to babies under the guise of foods and medicines.

The cream mixtures are readily digested, because there is not much to digest. The fact that infants thus fed cry for food continually is good evidence that their needs are not satisfied. Babies fed with this sort of slop grow fat for a while. The watery food inevitably produces fatty degeneration. This for a season swamps the little body with unhealthy fat. But the first crisis which happens along often takes away not only the unnatural fat, but the baby also.

The artificial mixtures contain entirely too much water in proportion to nourishing elements. The resulting malnutrition and the constant irritation caused by the inorganic minerals result in chronic diarrhea or constipation.

**The Right Way**

The best food for the newborn and growing infant is undoubtedly the mother's milk, provided that she is herself in fairly good health. Unfortunately, many mothers are unable to nurse their offspring, and if a healthy wet nurse cannot be secured, other food must be provided.

The best substitute for human milk, without question, is cow's milk, fresh, pure and undiluted, as it comes from the animal.

"Why", indignantly exclaims the trained nurse, when we give these instructions, "undiluted cow's milk is altogether too rich, it is indigestible for baby; if the milk is not boiled or pasteurized, germs and bacilli will surely create infectious diseases".

To this we answer: Our analyses show that the difference in composition between cow's milk and human milk is not enough to affect the infant. The danger lies not so much in overfeeding on "rich" cow's milk as in underfeeding on watery milk and cereal dilutions, and in poisoning the little body with inorganic minerals.

As regards germ infection and the necessity for pasteurizing the milk, the menace to health and life is greater through
malnutrition than through germs and bacteria. Germs we cannot escape, not even if we were surrounded on all sides by walls of air-purifying and antiseptic materials.*

*Since the foregoing was written we have learned that low vitality and morbid soil will develop perfectly normal microzyma into so called disease germs.

One of the foremost French bacteriologists claims that in the mouths of infants shortly after birth he has found almost every disease bacillus known to medical science.

William Osler; M.D., to whom the English language is indebted for the verb "to oslerize," says in The Principals and Practice of Medicine on page 151, in the chapter on Diphtheria:

"The presence of the Klebs-Loeffler bacillus is regarded by bacteriologists as the sole criterion of true diphtheria, and as this organism may be associated with all grades of throat affections, from a simple catarrh to a sloughing, gangrenous process, it is evident that in many instances there will be a striking discrepancy between the clinical and the bacteriological diagnosis."

In the first part of this sentence he states that bacteriologists regard as the sole criterion for the diagnosis of diphtheria the Klebs-Loeffler, or diphtheria, bacillus; in the last part of the sentence he admits that this bacillus is found in even slight catarrhal conditions, and he might add that it is found just as frequently in the mouth and throat of healthy infants and adults. This is a good example of "orthodox" scientific reasoning.

If germs and bacilli of themselves could destroy health and life, the human race would in a short time become extinct. Disease germs are omnipresent. They permeate the tissues of our bodies and in the intestinal tract swarm by millions. Whether they prevail depends upon natural resistance, or reserve force, and upon the disease soils in the system. The air we breathe is saturated with all sorts of disease germs or their microzyma.

Since baby cannot escape germ invasion, the real problem is how to increase the resistance of the little organism and how to purify it of morbid matter so that disease germs will not find anything to feed on.

Resistance depends largely upon proper nutrition. Diluted, watery milk, contaminated by inorganic minerals, is not a good nutrient; its nutritive value is still more reduced by pasteurizing or boiling. Heating milk or any other proteid food above 1500 F. coagulates the albumen, disorganizes organic compounds, precipitates salts and dissipates the life elements. This reduces the nourishing value and digestibility of the milk.

Nature does not provide the young animal with boiled or
Pasteurized milk, and we should not lower food values by such methods.*

* It is now admitted that pasteurization and boiling kills "newly discovered vitamins" which are the "life elements" constantly referred to in my earlier writings.

I do not wish to intimate, however, that scrupulous care and cleanliness should not be exercised in the selection and handling of the milk.

Wherever possible, secure the milk of a single healthy cow that grazes on green pastures or is fed on normal clean food mixtures. Milk from cows kept in stables and fed on brewery and distillery slops and other refuse should not be used.

Every vessel and utensil with which the milk comes in contact must be carefully scoured, submerged in boiling water, drained and kept in a light, airy place.

The nursing bottle, after each feeding, must be taken apart and carefully scrubbed, inside and out, in hot water with an addition of a little soda. It should then be left in pure, cold water, until the next feeding time.

2. When to Feed. Physicians quite generally recommend feedings at stated hours, in fixed quantities.

This is altogether wrong, it establishes at once the stuffing habit, does not permit the development of natural desire and its regulation. The infant very soon becomes accustomed to eating at certain times, whether it really needs the food or not.

Food should not be given until there is an actual demand for it, which will express itself in real hunger. By careful observation and experiment the mother will soon learn to distinguish the ordinary crying of the baby and the desire for food expressed by it. If this practice of feeding only when there is a natural desire for food is strictly followed, the infant will soon establish its own regular feeding times, usually at intervals of about three or four hours in the daytime. The stomach digestion of a feeding of milk will require about three hours, therefore a minimum of that much time should be allowed between feedings after the first few weeks.

If the mother can nurse her baby, it should be put to the breast upon awakening from its first sleep, either before or after bathing and dressing.

The first secretion of the breasts (colostrum) is not really a food, but performs an important function in cleansing the intestinal tract and preparing the digestive system to properly digest and assimilate the milk when it comes, usually about the third day.

3. How to Feed. If artificial feeding must be resorted to, no food at all should be given, except a few teaspoonfuls of water, during the first twenty-four hours after birth. During
the next few days, cow's milk should be given, well diluted—about one-half milk and one-half filtered or boiled water. From week to week the amount of water should be reduced until at the end of the second month the baby takes cow's milk undiluted.

4. Night Feeding. In the nighttime feeding should not be encouraged. During the first four months it is advisable to feed not more than once during the night. After that the child should be weaned from the habit entirely. This will be facilitated by giving a drink of water instead of milk.

5. Amount of Food. Discretion should be observed in determining the amount of food. Do not induce the baby to take as much as possible, rather as little as possible. Its welfare does not depend upon the amount of food consumed, but upon the amount which it can easily digest and assimilate.

When more food is given than the digestive organs can take care of, the entire mass may ferment and sour.

6. Grain Extracts. If undiluted milk proves too rich, grain water may be added. In order to prepare this, take clean grain as it comes from the field, crush it in a hand grain mill or a new coffee mill, take three tablespoonfuls of the crushed grain to one pint of cold water, and boil on the stove for one hour; or in the fireless cooker for two or three hours, in which ease use a little more water at the start. While the gruel is boiling over the fire, add enough water to allow for evaporation and absorption. When thoroughly cooked, strain the gruel through a fine cloth or sieve. Add one tablespoonful, or more if necessary, to each milk feeding.

When baby is constipated, add to the milk, grain extract made from oats, and frequently cool the bowels with cold water. This will cure the most stubborn constipation. If the bowels are too loose, add to the milk, extract made from barley or wheat.

The small particles of hulls in the grain extracts improve digestion and evacuation, in a mechanical manner. They permeate the curds and keep them from coagulating too solidly, thereby facilitating the penetration of digestive juices; they also exert a mild stimulation on the walls of the intestines, thereby increasing the peristalsis of the bowels and evacuation of feces.

7. Baby's Natural Medicines. Fruit juices and scraped raw ripe pear or apple and the pulp of cooked fruits such as prunes or figs without addition of sugar or sweetening of any kind, are baby's finest medicines. They increase the supply of organic salts for blood, nerve and bone building and for purposes of elimination. They are nature's own chologogues, laxatives, tonics and antiseptics. They keep the little body sweet and wholesome. All babies under our care receive fruit juices beginning with the second week.
During the first two months, give one teaspoonful of orange juice, grape fruit juice or prune juice, one hour before or after each nursing. After the second month, gradually increase the amounts of fruit juices and begin to add raw pear or apple scraped with a spoon or dull knife, or the mashed pulp of fully ripened peach or grapes.

8. Weaning the Baby. Nursing infants should be weaned from the breast after the eighth or ninth month. From the sixth or seventh month, both nursing and bottle-fed babies should begin to take some solid food. The best of these to begin with are whole-grain cereals, gruels, raw and cooked fruits and tender vegetables in small amounts. Mealy baked potato is one of the best foods, better than the cereals.

9. Feeding After First Year. After the lapse of the first year, the solid foods are gradually increased and the milk reduced in quantity. Eggs should not be given before the eighteenth month, then soft-boiled or poached. During the second and third year half an egg twice or three times a week is sufficient; after that an egg at a time may be given once or twice a week.

Meat and all other foods prepared from the dead animal carcass are bad enough for adults, but it is inexcusable to give them to tender infants and children.

Dog fanciers, when they sell a valuable canine, usually advise the buyer not to give the animal any meat before the second year, lest it become a victim of distemper; and dogs are naturally meat eaters.

Well informed physicians now generally advise not to give meat to children before the fifth or sixth year. They have learned this much from the nature cure people.

Foods undoubtedly have a powerful influence, not only on the physical body, but also on the mentality and the emotions. These problems will be interesting subjects of investigation for the food chemist and psychologist of the future. In general, we may say that flesh foods are stimulating and feed the passionate nature, while fruits and tender vegetables refine and stimulate brain and nerve matter as well as the intellectual, emotional and spiritual activities. Cereals, nuts and pulses build and repair the physical body and supply the body with heat and muscular energy.

The majority of animals adhere strictly to one kind of food, and therefore faithfully exhibit in their mental and emotional characteristics the effects of different food materials. Ferociousness we find personified in the carnivorous bulldog, lion, tiger and panther (that is why soldiers are fed on meat three times a day); gluttony and omnivorous voraciousness in the hog, chicken and hyena; cold-blooded cunning in the fox, and cruelty in the cat. The intelligence of the carnivorous animals displays itself mainly in the cruel cunning with which they stalk their living prey. It resembles in quality the low
intelligence of the human criminal.

Personifications of great physical strength, intelligence, endurance, patience, gentleness, fidelity, affection and self-control, we find among the vegetarian animals. The beaver, the arboreal ape and the elephant are especially noted for their intelligence; deer, antelope and sheep for gentleness; the horse for its almost human intelligence, affection and fidelity; oxen, elephants and camels for their great strength and endurance.

Meat is detrimental to the child in every way, physically, mentally and morally. The poisonous acids and alkaloids which it contains clog the capillary circulation, causing anemia, coldness of the extremities and defective elimination through the skin. This results in congestion in the interior organs, high blood pressure in brain and heart, headaches, nervousness, irritability, tendency to fevers, inflammations and catarrhal conditions.

With the meat, the child often absorbs the eggs of worms, tubercular bacilli, and other parasites and disease germs. Certain forms of epilepsy, St. Vitus' dance and hysterical conditions are due to uric acid poisoning and to other pathogenic materials and ptomains contained in flesh foods. Such patients, in times of crises, frequently emit pronounced odors of raw meat or uric acid. Strictly vegetarian diet, combined with other eliminative natural methods of treatment, cures the majority of these cases.

Most of these poisonous acids, alkaloids and ptomains contained in the flesh of dead animals are powerful stimulants. I have frequently noticed that people who have abstained from meat for a long time, when they first partake of it again experience sensations and exhibit symptoms resembling those of alcoholic intoxication.

We have learned that these stimulating extractives of flesh foods chemically closely resemble caffeine, thein and nicotine. The use of one or more of these stimulants invariably creates a craving for the others. This explains why a heavy meat eater is usually a confirmed coffee drinker or inveterate smoker, and vice versa; and why we find it almost impossible to wean people from one of these stimulants as long as they persist in taking the others.

The legumes or pulses—peas, beans and lentils—are close seconds to meat in acid-producing qualities. Eggs contain considerable ready-made uric acid and a great deal of sulfur and phosphorus. These may become dangerous to the organism. For these reasons, meats, legumes and eggs are always danger foods for the child.

Children brought up on such foods will show the effects in nervousness, irritability, lack of self-control, craving for cigarettes and alcoholic stimulants. The most serious aspect of this question lies in the stimulative influence of meat poisons.
on the sex centers. It is a well known fact, verified by close observation, that flesh foods stimulate the sexual passions to a marked degree. This tendency is greatly increased by the use of coffee, tea and alcoholic stimulants in the form of wines, liquors or medicines. If the sensitive nervous organism of a child is overwrought by these powerful irritants, there can be but one result; precocious sexual awakening.

From the third year the child may gradually adopt with slight appropriate modifications, a diet as outlined under Sec. I, No. 10, and Sec. X, No.7.

SECTION XL

Exercises in Infancy

1. Exercises in Infancy. Proper exercise is important from the very beginning of life. A baby will follow its natural instincts for exercise if allowed to do so, by working its arms and legs and writhing its little body in all directions, if not unduly hampered by tight clothing and bandages. A few nude air baths every day will afford excellent opportunity for baby's gymnastic stunts.

After he is a few months old he may be placed on his stomach, when he will exert himself vigorously by trying to raise his head, to turn around, or to raise himself with his arms. He will soon learn to roll over and to creep lie nay now be pulled up gently by his arms and lowered again a number of times in succession.

When three or four months old he may be lifted by one arm or by both arms; by the right arm and left leg, or by the left arm and right leg. When the baby is six or eight months old, he should be strong enough to rise from his back to a sitting position. This may be encouraged by holding down the feet. I have known a number of nature cure babies who at six months of age clung tightly to a stick while being lifted a few feet from the bed. Another good exercise greatly enjoyed by the youngsters is to roll them back and forth on a bed.

The average healthy child will secure ample exercise while learning to walk and run and while playing with simple toys or with other children; but this may be supplemented to good advantage by special exercises devised by the father and mother. Nothing is better for the health and happiness of both parents and children than to join in merry romp and play.

Between two and five years of age the child may be taught more difficult stunts, performed either by himself or with the assistance of the father or mother; but swinging the child high overhead, throwing him up and catching and other dangerous tricks should be avoided. They are risky and have very little effect in developing the body of the child. The best exercise at this age consists in outdoor play and games.
From the sixth year, the question of exercise becomes a more important one, especially since the children are confined for many hours in school rooms. If exercise at this time of life, through play and games and special gymnastics, is neglected, it may affect health, strength and efficiency of the child for life.

Those of good physique and ample strength may gradually take up and practice the exercises for adults outlined in sections XXI, XXII, XXIII, XXIV.

2. High Chair. A baby should not be put in a high chair until he is quite well able to hold the spine and head erect, and should never be left in a chair for any length of time. If a baby is forced to maintain a rigid, sitting position for a considerable time, before the bones and muscles are sufficiently developed, this may produce deformity of the spine. Maids and nurses, if not properly supervised, sometimes fasten a baby in a high chair and leave him there to take care of himself for long periods.

3. Toys. Since most babies have a habit of putting everything into their mouths, toys must be selected that can do no harm. They should have no paint, no sharp points or corners which might hurt the eyes or mouth, and must be of material which can be easily and thoroughly cleansed. Hairy and woolly playthings are unsafe, being unclean and germ carriers. Objects small enough to be swallowed must never be put within baby's reach. The simpler the playthings the better; a few clothespins, empty spools, or other simple objects are better than expensive toys.

SECTION XLI

Baby's Ailments

1. Hernia As a result of a weakly or sickly condition of the mother during pregnancy and of faulty prenatal management, many children are born ruptured. So far I have not known a single nature cure baby that was born ruptured. Such defects are due to weakness of the tissues. This results from mineral starvation. The tissue walls contain too much mortar (protein) and not enough building stone (mineral salts). Prevention of hernia, therefore, lies mainly in proper diet of the pregnant mother, but all the rest of the prenatal regimen described in these pages is of great importance in preventing this and other ailments and deformities.

There are three principal points at which rupture or hernia may take place in infancy—at the navel, in the groin, and at the line between the navel and the lower end of the sternum. Other kinds of ruptures are extremely rare.
2. Umbilical Hernia This is a protrusion of the intestine at the navel. It is the most common rupture in infancy. Pulling on the cord during childbirth, urging at stool or violent crying may result in rupture. The umbilical ring first expands and this forms a pouch into which one of the folds of the small intestine protrudes.

Treatment: Of primary importance is the diet as outlined herein. The baby must have plenty of fruit juices in order to reinforce the mineral salts in the milk. Cold bathing is very beneficial. The rupture itself should be cleansed several times a day with warm water. This must be followed by a wash with cold water mixed with lemon juice. Gentle, passive exercise, such as raising, lowering and twisting the limbs from side to side, also raising and lowering the body while supporting the shoulders and head, is of especial value.

The rupture must be reduced and kept from protruding by placing over it a large button or other article of similar shape, wrapped in gauze and held in place by broad strips of adhesive plaster. The adhesive tape is fastened over the button crosswise and must be applied in such a manner as to draw the skin from all sides over the rupture. Instead of the button, a compress made of gauze may be laid over the rupture and held in place by one broad adhesive strip. The covering of the rupture must be removed and renewed every day in order to allow cleansing, as before described.

When the child is old enough to exercise by himself, he should be taught special movements of the body and the limbs which develop the muscles of the abdominal region.

3. Ventral Hernia. This occurs along the middle line of the body between the navel and the breastbone, sometimes below the navel. The rupture may not be larger than the size of a pea or small marble, and may disappear on pressure. The treatment is the same as that of umbilical hernia.

4. Inguinal and Scrotal Hernia occur in infancy or in adult life; sometimes the inguinal canal does not close after the descent of the testes from the abdominal cavity into the scrotum, and the intestine descends through the open canal, thus producing the rupture. These forms of hernia become aggravated by coughing. They can be reduced immediately with gentle manipulation while the patient is lying on his back. This kind of rupture may be distinguished from hydrocele by the fact that in reducing it goes back easily with a gurgling sound. Hydrocele is not affected by coughing. A hernia is opaque to transmitted light; hydrocele, transparent.

These ruptures should be protected with a well-fitting truss. This has to be removed daily for cleansing of the parts. Appropriate exercises, passive and active, together with cooling sitz baths and washes with cold water and lemon juice are the best remedies for these, as well as of other forms of rupture.
5. **Congenital Hernia** occurs in the form of inguinal hernia and has to be treated in the same way. Ruptures of any kind must be reduced and properly supported. Constipation and consequent urging at stool may cause or aggravate any form of hernia and must, therefore, be overcome by the right treatment described under section XXVI, No.1.

6. **Colic.** This is usually caused by indigestion due to overfeeding, improper feeding, or too frequent feeding. The intestines are distended with gas, giving rise to a severe pain. The baby cries sharply, alternately drawing its legs up to the body and kicking them away. One of the quickest means of relief is a small enema of warm water and gentle circular massage of the abdomen from right to left. Food should be withheld until the symptoms have disappeared. The giving of milk or other food may quiet the attack temporarily, but the pain is apt to return with greater intensity. Warm water may be given if the baby will swallow it.

A baby managed in the natural way prenatally and postnatally is not likely to suffer from this ailment. Constipated babies are more prone to it than others.

Colic may also be caused by sudden chilling. In that case a warm bath for five or ten minutes, followed by gentle body massage will bring about a warm reaction.

7. **Convulsions.** These cause a great deal of anxiety to the fond mother. They are always reflex symptoms of some slight or serious internal disturbance due to wrong management. They commonly result from some form of auto-intoxication caused by digestive disturbances, and the resulting systemic or drug poisoning. An inactive condition of the skin, bowels or kidneys will favor auto-intoxication and convulsions. If proper care is taken to keep the system pure, and the organs of elimination in active condition, convulsions will not occur.

The best treatment during an attack is a quick, cold rub all over the body; application of a whole body or trunk pack; gentle soothing magnetic massage, and neurotherapy treatment. These treatments draw the blood into the surface and relieve congestion in the brain and nervous system.

8. **Ailments of Teething.** Many ailments of children are laid to teething, but this is a mistake. Well managed, healthy babies go through the teething period without any trouble whatsoever. This is practically always true of nature cure babies. When, however, the little body is heavily encumbered with hereditary and acquired morbid materials, food poisons and disease taints, the process of teething will not run its natural course and may precipitate any form of disease crisis.

When teething is difficult, it is frequently associated with digestive disturbances. Diarrhea may alternate with constipation and vomiting is of common occurrence. The baby may be restless and fretful. He tries continually to bite on something in order to facilitate the projection of the teeth.
through the hardened gums.

   No teething lotions or soothing medicines of any kind should be given for the relief of pain in teething. They all contain poisonous sedatives which benumb and paralyze the nerves and have serious after effects upon the system. They usually contain opium in some form, or other narcotic drugs.

   The only way to prevent these and other infantile ailments is to keep the little body as nearly normal as possible through the natural treatment described in these pages. If this is closely adhered to, it will prevent, in many cases, the development of even measles and other common eliminative infantile ailments.

   During this critical period in the baby's life the diet must be extra light; starchy food should be reduced to a minimum and replaced by raw and cooked fruits and vegetables juices. Cooling sitz baths will help to keep the bowels active and to abate internal fever.

   **9. Acute Catarrhal Disease.** Acute catarrhal diseases of infancy such as croup, cold in the head, acute bronchitis and whooping cough, are different forms of acute elimination through which Nature tries to purify the little body from hereditary and acquired accumulations of morbid matter, systemic poisons and disease taints.

   In accordance with this conception of acute diseases, as purifying, healing efforts of Nature, we would not do anything to check or suppress elimination but cooperate with Nature in her purifying, healing efforts. How we do this has been fully explained in other parts of this volume. (Section VIII)

   The natural treatment is very much the same in all acute inflammatory ailments. Feeding must be reduced to a minimum. If the baby does not insist upon eating, nothing should be given except water with acid or sub-acid fruit juices, such as lime, lemon, grape fruit and orange. If the temperature does not run high, say not above 100 or 102 deg, frequent ablutions with cold water at intervals of from one to two hours will be sufficient to promote heat radiation and elimination of morbid matter through the skin and other organs of elimination. If the temperature runs' higher, say between 102 and 105 deg, wet packs must be applied, and renewed when they become hot or dry.

   The wet packs are of especial value in all kinds of cough; whether it be the ordinary cough, croupy cough or whooping cough. A whole body or trunk pack, with or without a throat pack, will give almost instant relief. In many instances where baby is making the night hideous for the anxious mother, with it's coughing, a well-applied whole body pack, or a combination trunk and throat pack, will relieve the coughing almost instantly, and induce restful sleep.
In serious cases it is always advisable to call in a natural therapist or some other drugless physician, if one can be reached.

The mother should not forget that all acute diseases, after they have once developed, must run their natural course. She must, therefore, not become impatient and lose faith in the natural treatment if it takes a week or more to cure a common cold in the head or an attack of bronchitis, or if it takes from two to eight weeks to cure a case of whooping cough. Serenity, patience and cheerfulness are the primary requisites of the nature cure physician.

PART IV

BABY BOOK

Natural Therapeutics has undoubtedly solved the problem of treating human ailments. All other schools and systems will in time have to adopt the natural way. It is the hub of the healing art; all therapeutic methods radiate from it like spokes from a wheel.

Natural Therapeutics, however, has something better to give than treatment of disease, and that is prevention of disease. If children were brought into this world in the manner ordained by Nature and reared in harmony with the teachings of natural philosophy, disease would soon be a thing of the past. Human beings would then enjoy good health and be as beautiful and perfect in their kind as are animals, which live in the freedom of Nature, guided by instinct and therefore in harmony with the laws of their being.

We must begin, then, with prevention, for prevention is always easier and cheaper, than cure. But where must we begin to study the prevention of disease? Some will say, "At birth, because that is the beginning of life." Not so: that would be too late. The mould is made and the foundation laid for health or disease, for happiness or suffering, for efficiency or deficiency, before the human being in process of creation sees the light of day.

"Then," it may be said, "we must begin with prenatal influence, for the physical, mental, emotional and moral habits of the mother influence powerfully the development of the new life she is carrying." True—but we must start earlier than that. The making of the human being begins with mating and conception. All subsequent development depends upon the right start.

SECTION XXXII

Heredity

1. Importance of Correct Mating. Of primary importance in the sacred rite of procreation, as already intimated, is mating. This should take place only between descendants of the same subrace, or of closely related subraces such as the Indo-Caucasian and Celtic.

If the racial descent of the marriage partners is so far removed that it has produced pronounced differences in racial
characteristic—as in the case of the swarthy Mexican and white skinned Englishwoman, or the dark eyed Magyar and blue-eyed Scandinavian—then procreation becomes miscegenation and degenerates into mongrelization of the offspring. Everywhere in the animal and human kingdoms Nature has set the mark of disapproval on the mongrel. The offspring of miscegenation is doomed to deterioration and extinction unless assimilation of the elements of a lower race by a higher takes place sparingly and gradually.

The law of racial purity may be summed up as follows: When a member of a higher race cohabits with a descendant of a lower race, the offspring of the union loses more or less the characteristics of the higher race and reverts in physical, mental and moral traits to the level of the lower race.

The constructive results of racial purity are evident in Hindus of the higher castes; in that portion of the Jewish race which in mating has faithfully adhered to the Law of Moses, and in the blond and blue-eyed remnants of the Indo-Caucasian and Celtic races in Northern Europe and North America. The destructive results of miscegenation are plainly evident in the mongrelized population of Mexico and everywhere in the half-breed and many kinds of mixed breeds. These usually fall below the physical, mental and moral standards of the parent stock, and almost invariably revert to the customs and habits of the inferior race.

2. Use Heredity. Use heredity deals with the transmission to offspring of acquired physical, mental and moral characteristics of the parents. According to this law as it has been formulated, the chances of the offspring for long life, health, mental efficiency and moral stamina, other conditions being favorable, are better in direct ratio to the advancing age of the parents at the time of conception. While this is contrary to popular opinion, which assumes that younger parents produce more perfect offspring than older ones, the fact of use heredity is proved, both in the animal and human kingdom, by common observation and statistical evidence.

The working of the law is based on the fact that the procreative elements of the parents, or rather the microzyma of those elements, cannot contain the impress of physical, mental and psychical characteristics which at the time of procreation were not developed in the threefold organisms of father and mother.

The age of the father at conception is called the "birth age" of the offspring and determines its birth rank. While the father and previous male ancestors, for reasons hereafter explained, seem to exert greater control over the mental and physical characteristics, the mother furnishes the nutrient soil for physical growth. This does not mean that she exerts no control over the mental and psychical characteristics of the offspring; in addition to her influence through use heredity she has added opportunities through prenatal influence and postnatal training.
According to this law, then, the chances of the offspring for excellent physical, mental and moral development become better as the age of the father at the time of procreation advances beyond thirty five; while the physical condition of the mother for reproductive function is best below thirty five years.

But we must not overlook the fact that too great a discrepancy of age between the man and woman may become the cause of physical and mental incompatibility, of aversion and great unhappiness, especially on the part of the younger woman.

Extensive statistical evidence seems to prove that the birth age of the mother has been of less importance than that of the father. As will be shown in Natural Eugenics, the majority of famous men in all lines of human endeavor had old male ancestors, while the mothers and previous female ancestors were of much younger age at the time of conception.

This may be accounted for by the following reasons:

The man is usually considerably older than the woman at the time of marriage. Men, as a rule, devote much more time and effort to acquiring a scientific, professional or business education than do women. This has been true in the past more than it will be in the future. Thrown early into the competitive struggle of life men generally have had to make greater mental and physical effort than have women.

These points are of considerable importance because it has been proved that it is not inherited brain mass and mental capacity, but strenuous and persistent effort that intensifies use heredity. The earlier this begins and the longer it continues before procreation takes place, the better the chances of the offspring for physical, mental and moral capacity.

The reproductivity of the mother has usually ceased at thirty-five. Though she be capable of childbearing a few years longer, usually conception has been avoided after that age. Men under favorable conditions remain reproductive to advanced age. Some of the world's greatest men descended from fathers over sixty years old.

That intellectual and creative capacity has followed the male line of descent rather than the female line, is indicated by the fact that the high intellectual capacity of many eminent men has skipped their daughters to reappear in male descendants. This may be partly accounted for by the fact that the daughters in their limited spheres of activity have not had the opportunity to unfold inherent intellectual capacity to any conspicuous degree.

There has been a tendency in some quarters to criticize the general entrance of women into professional and commercial life and to dilate upon the adverse influence this will have
upon womanly characteristics and family life.

In the light of the knowledge we possess upon the subject of use heredity, it is safe to say that any such problematical drawbacks will be far outweighed by the general postponement of the marriage age. This will insure not only better physical fitness but also higher intellectual development and greater moral stamina on both sides of parentage.

The tremendous benefits which this increased hereditary endowment will confer upon future generations cannot be overestimated. Greater intellectual and economic equality between the sexes will emancipate woman from degrading sexual subservience. Under the old order, sex appeal was too often her only stock in trade by which to attract and hold the male and thus to secure a living. Economic independence will insure greater consideration and higher esteem for the woman on the part of the man. It will go a long ways toward solving the problem of birth control in a natural way, by leaving it more largely to the judgment of the mother.

We find the law of use heredity according to birth age verified in the intelligence and moral development or obliquity of races, nations and tribes all over the earth—The lower the average birth age of a race or nation, the lower, other things being equal, the intellectual and moral development The greatest development and efficiency is found among those nations where marriage is delayed to a later age through custom, economic necessity, professional or military training.

The following quotation from "Control of Heredity", by Casper Lavater Redfield, is of interest in this connection:

"In general it may be said that wherever there are no restraints upon the sexual propensities, as with the Digger Indians, the Fuegians, the Andamanese, the Wauraus of the Guianas, the Bushmen and the tribes along the Gabbon river, there we find reproduction taking place at the earliest possible age, and the lowest grade of intelligence. Where we find some special circumstances or customs that delay the age at which reproduction takes place, as with the Patagonians, the North American Indian and the Polynesians, there we find considerably higher grade of intelligence.

"Where we find the custom of marrying late in life, as was customary with the Greeks and the Romans, there we find a very high grade of intelligence. And where we find a fortuitous succession of very late births, there we find the very great men of the world's history.

"In other words, the longer the time in which the individuals have in which to use, develop and strengthen their brains before reproduction begins, the greater and more powerful are the brains of their descendants."

In Volume IV of this Series I shall quote elaborate and
highly interesting statistics from Redfield, which reveal the effects of the various birth ages on physical, mental and moral characteristics. I shall confine myself, for the present, to the statement that, with few exceptions, the great artists, scientists, philosophers, statesmen and philanthropists were born from fathers whose ages ranged from forty to sixty-five years at the time of the procreation of their famous offspring.

The existence of these laws and principles as facts in nature is very evident in the training of racehorses and of other animals along certain lines of proficiency.

3. Pernicious Heredity. The effects of deteriorating and destructive heredity prenatal and congenital influences have been traced and commented upon in so many different ways that I do not believe it necessary to enter deeply into this phase of the subject. Various authors have filled entire volumes with the unsavory family histories of the descendants of the Jutes, Ishmaels and other drunkards, prostitutes, degenerates and criminals, which prove positively the transmission of morbid and pernicious traits through successive generations. It has been proved statistically beyond the shadow of a doubt that youthful delinquency, pauperism and criminality are the aftermath of immature marriages.

The laws of use heredity and prenatal influence, like all other natural laws and principles, manifest along opposite lines of expression. It remains for us to determine whether we shall align ourselves with their destructive or constructive activities. The effects upon ourselves and our offspring will show accordingly.

If I succeed in arousing the consciousness of prospective fathers and mothers to the glorious privileges and enormous responsibilities which these laws of nature confer upon them, then my labor will not have been in vain and I shall feel deeply gratified.

SECTION XXXIII

1. The Creative Alchemy of Love and Affection

Procreation—as is the case with everything else pertaining to the constituents and functions of the human entity—takes place on three planes of being, the material (physical and spiritual), the mental and the psychical planes. Which of these elements shall predominate in the offspring depends upon the mixture and adjustment of qualities in the triune makeup of the mating couple. In order to fulfill the law and to draw the divine blessing upon themselves and the fruit of their union the partners in the procreative function must be united by the bonds of love, or at least by the ties of true affection.
The source of creative genius is love and wisdom, and the essence of intelligence and power is sincerity and goodness. Without these, intelligence degenerates into selfish cunning, power into self-destructive brute force. The spring cannot rise higher than its source; its water cannot be pure and wholesome when contaminated by impure admixtures from filthy surroundings.

It is not generally known that use heredity pertains to intellectual and psychical qualities, as well as to the physical material. Animalism breeds nothing but selfish animalism. The vampire who craves and absorbs the love of its victims and robs them of vital energy, without being capable of feeling or bestowing affection, is the child of a discordant union—of brute animalism on the part of the man, of secret aversion and hatred, usually, on the part of the woman. These bestial and degrading tendencies on the one side, and unrequited love craving on the other, breed sex perversion, and propagate the harpies who delight in the seductive power of superficial beauty, while gloating over the weakness and ruin of their victims.

True love and affection, paired with intelligence and goodness; liberate the creative elements necessary to the production of perfect offspring.

The finer qualities of mind and soul open the fountains of life on the higher planes, liberate and harmonize the male and female procreative fluids, and charge them with the purest and most potent intellectual, spiritual and psychical elements.

The divine fire of creative genius burns only in the love aura of truly mated couples. It is true that these are rare under our artificial, unrighteous social institutions, and that accounts for the rarity of complete manhood and womanhood.

Perfect offspring, endowed with beauty and power of body, mind and soul, destined to shed through life a radiance of health, happiness and helpfulness—to love and be loved—issues only from the union of love and affection with intelligence and goodness.

"Love lieth at the foundation" (of all that is). "Love is passion, enthusiasm, affection, heat, fire, soul—God."

To the extent that love enters into the holy rite, to that extent its attributes will be absorbed in the threefold organism of the woman and become active in the child building in her womb. While she loves her man more than ever, her most passionate affection is centered in the new being in process of development. On it she bestows the purest and best in her food and drink, in her thoughts, emotions and secret desires. Fear, worry, anxiety, jealousy and hatred are strangers to her soul; these are the emanations of the lower spheres—she lives in heaven.

Somebody endowed with deep insight into these matters has
said:

"Whatever male and female shall truly will for, hopefully pray for and earnestly yearn for, when love pure and holy is the nuptive ascendant, in form, passionate, affectional, divine and volitional, that prayer shall be granted, and the boon be given—but the prayer must precede."

What are the direct effects of the marital rite upon the participants? If the sex attraction operates on the physical material plane only, if lust instead of love presides at the matrimonial feast, then temporary gratification of erotic craving will be followed inevitably by monotony, satiety, gradual revulsion and aversion, culminating in a morbid craving for change and variety. The partners in carnal self-indulgence are intuitively aware of these tendencies to marital unfaithfulness, and, therefore, easily dominated by distrust and jealousy.

The procreative function is attended by complete satisfaction, buoyancy of body and mind and lasting happiness only when sex attraction operates on the higher and highest planes of being, as well as on the lower, when desire and impulse are operative on both sides. Thus only will the generative function fulfill its sacred purpose and confer the highest possible benefits upon parents and offspring.

The woman, being the more highly sensitized, must be responsive to the call of holy passion. To force unwilling compliance will ruin the woman, kill her love and curse her offspring. Balzac says: "He who begins with his wife by a rape is a lost man." It is impossible for a wife to love unless she is won, not forced to compliance.

2. Sexual Intercourse During Pregnancy. Sexual intercourse should be considered the most sacred function of the human entity. From the highest and best viewpoint it should be exercised only for the propagation of offspring. However, considering the present stage of ethical and moral development, temperate indulgence may not be wholly condemned. Excessive intercourse is always weakening and harmful to both participants. We must remember that the sex fluid is the carrier of the life force. It is that which constitutes strength, resistance to disease, initiative and genius. During abstinence from intercourse the sex fluids with their creative energy are absorbed through the inguinal glands into the organism and increase physical, mental, moral and spiritual capacity and energy.

Set rules for frequency of intercourse cannot be given. This must depend entirely upon individual conditions. One safe rule is that after indulgence there should be no feeling of satiety, weakness and exhaustion. The more frequent the indulgence the stronger will grow the power of habit and of passion and the greater will become the abnormal craving. It is the same with all other appetite and passions. The more frequently they are indulged, the stronger they grow, until
they attain complete control and develop into destructive habit

A free and confidential understanding in regard to these matters between those who contemplate matrimony would go far to prevent marital misery. A great deal of unhappiness arises from the fact that mates in the matrimonial union often labor under misapprehensions concerning the attitude of each toward the sex relation, and are prevented by excessive sensitiveness and delicacy from frankly discussing it. (For further discussion of this subject, see page 390, Volume I.)

There is no problem of married life that needs more thorough mutual consideration and understanding than this one. Lack of it accounts for a great deal of "incompatibility," loss of love, revulsion, hatred, and the final tragedy in the divorce court.

Among animals, no female allows intercourse after conception. In this respect as in many others, man has sunk below the natural standards of the animals. No greater crime can be committed against the woman and the unborn life.

It is a sad commentary on our system of education, scholastic as well as religious, that our young people are not instructed before and after marriage in these all important laws of Nature. To do this should be the province of the priest who unites them in marriage, or of the family physician, if the parents have failed in their duty.

It is well known (notwithstanding the denials of medical skeptics) that the unborn infant may be "marked" by transitory impressions, especially by strong emotions; that even insignificant parental characteristics are reproduced in the offspring. Is it any wonder, then, that the most powerful of human emotions should leave its impress on the growing brain and sex centers of the fetus, causing abnormal and precocious sex consciousness?

All too often is sex perversion born and bred in bone and flesh, before the child sees the light of day. The mother cannot be blamed for this "slaughter of the innocents"; she has not been instructed on the subject. Though she intuitively senses the horror of it, she submits, in order to maintain her hold upon the man—and many a life is thus cursed before it is born. The fault lies primarily with those of the medical profession who teach our young men that the free indulgence of sexual passion is not only legitimate, but a necessity to manly vigor.

This dictum of pseudo-science is almost universally concurred in by spiritual guardians. No greater lie was ever promulgated from the blackest abyss of Hades. If our young men were taught that greater happiness is to be attained by the exchange of tender affection than by the indulgence of the coarser animal appetites, that the creative forces thus preserved develop and strengthen their own finest capacities
of body, mind or soul, they would wisely and chivalrously protect mother and child, at the same time conserving their own physical and moral integrity.

In no other way is it possible to call forth the deepest gratitude and unfailing esteem of a true woman. Many a man whom we have thus advised has become a lifelong friend in consequence.

3. Limitation of Offspring. I believe that the unlimited production of offspring, encouraged in some quarters for swelling the ranks of religious bodies or for increasing tax paying and cannon-fodder material, is a misfortune, both to the family and to society. Limitation of offspring, in accordance with the means and circumstances of the parents, is not only justified but should be encouraged. In any case, the production of offspring entails great responsibility upon the parents and if they cannot properly comply with the needs and rights of their children, they fail in their responsibility and duty.

Any method, however, which interrupts intercourse or prevents conception in an artificial way, is absolutely to be condemned, because this has very harmful and positively destructive effects upon the physical, nervous and mental organism of those who thus try to cheat nature by the suppression of a natural process. In our professional work we frequently meet the victims of such pernicious practices. The ordinary contrivances for prevention make of intercourse something akin to masturbation. This is also true of intercourse without orgasm which is strongly advocated under various guises. The use of poisonous antiseptics and germ killers in warm water douches is not essential for prevention, and is highly injurious. These chemicals have a tendency to poison the sexual organs and to produce in time atrophy, many kinds of female disorders, and tumors. Undoubtedly the greater number of so called female troubles and malignant tumors in later life are caused by curetments, antiseptic douches and the use of poisonous drugs, for producing abortion. The only legitimate methods of birth control are abstinence or common cleanliness.

There is nothing more conducive to the physical, mental and spiritual health and development of a woman than childbearing and child rearing in harmony with Nature's laws, as outlined in these volumes. Under favorable conditions it is not a thing to be dreaded, but to be looked upon as the greatest of blessings and opportunities in the life of a woman. Natural philosophy and practice takes these problems of progeneration, childbearing and childrearing out of the domain of uncertainty and haphazard management with its dire consequences, and makes eugenics the most exact of all sciences and the sublimest and most enjoyable of all the arts.

4. Determination of Sex. Numerous theories have been advanced concerning this interesting subject. Many attempts have been made to wrest from Nature the secret of sex
determination and numerous more or less ingenious methods have been recommended for sex control.

I know of one method only which seems to have a rational basis and which has proved of practical value. Observations seem to prove that the right ovary liberates male ova only, while the left ovary discharges female ova. The two ovaries discharge ova only at alternate menstruations.

With this data at hand, it is possible to determine the sex of a child after one birth has taken place. Suppose the first child was a boy. By consulting our pregnancy table (page 377) we can determine when the last menstrual discharge took place. This menstruation liberated a male ovum; the next menstruation would liberate a female ovum, the next a male, etc.

Thus, using the last menstruation period before the last conception as a fixed point, it would be possible, figuring from period to period, to determine the sex nature of the ovum to be discharged at each following menstrual period. Account is taken of all regular periods during the time menstruation is suspended in pregnancy. Thus, conception may be timed in such a way as to impregnate at will a male or female ovum.

This solves in a simple, rational manner another of Nature's riddles, namely, the reason for the practically equal division of the sexes.

SECTION XXXIV

Prenatal Influence

There exists just as much diversity of opinion among scientists concerning the reality of prenatal influence as about race heredity, use heredity, disease heredity and many other mooted problems of science and philosophy, which we shall study in Vol. IV of this series. In the following I shall present and examine impartially the various theories and opinions concerning prenatal influence; then we shall be better prepared to draw our own conclusions.

1. Medical Science Denies Prenatal Influence. Medical men, as usual cocksure of the correctness of their theories and hypotheses based on the "latest discoveries", deny and ridicule the possibility of prenatal influence, and relegate it to the rubbish heap of popular superstitions. They base their judgment on the fact that no nerves pass from the body of the mother through the umbilical cord into the growing fetus in the placenta, which forms the soft protecting nest of the new life within the womb. They claim that since no direct nerve connection exists between the two, mental and emotional vibrations cannot be transmitted from the brain of the mother to the brain and nervous organism of the fetus.
Are there no other means of communication between the mind of the mother and the brain of the unborn!

In the volume dealing with Eugenics we shall learn how universal intelligence and creative will become individual intelligence and personal will.

Cosmic vibrations do not flow into the gray matter of the human brain over coarse physical nerve tracts. They come over the psychical wireless which connects the human soul with the world Soul, the individual intelligence with the universal or cosmic intelligence the human will with the divine will.

Since, as proved by modern brain and nerve anatomy, immaterial cosmic intelligence and "power to will" fashion the brain of the mother into physical material centers for the expression of human intellectual faculties, capacities and powers, why cannot these cosmic vibrations act in like manner over the psychic wireless through the soul and mind of the mother on the brain and nervous system of the fetal organism?*

These epoch making discoveries and revelations of modern brain anatomy are explained in Vol. IV of this Series, *Natural Eugenics—Man Building on the Physical, Mental and Moral Planes.*

Why should the wireless, which transmits impulses of intuitive intelligence from the great source of all intelligence and creative energy into the soul of the mother, cease to operate at that point, and fail to transmit its message to the brain and nervous system of the fetus which is most intimately related and connected with the organism of the mother?

What about the phenomena of hypnotism? Absolute control of the subject's mind, through the intelligence and will of the hypnotist does not depend upon the existence of an umbilical cord and physical nerve connection between the two. The hypnotist, by silent command, may call his subject from a distance, far beyond the reach of his voice.

People telepathically attuned may communicate in like manner, spontaneously, or by conscious intent. Why then should we doubt the possibility of vibratory correspondence between the mental and emotional conditions of the mother and the plastic nervous organism in process of development within her womb?

If a complexity of sound can impress itself permanently upon the wax cylinder of a phonograph, or what is still more marvelous, if the photographic rays of passing scenes can be fixed and retained in the picture film, why should it be impossible for the mental and emotional vibrations of the mother to impress and modulate the molecular and cellular constituents of the fetal brain and nervous organism?
I have compared this creative power of the mother mind to the process of electrotyping. As the particles of metal in suspension in the fluid adhere to the spoon that is to be coated with silver, so the atoms and molecules in the gray matter of the brain of the fetus group themselves in harmony with the thought forms and emotional vibrations of the mind and soul of the mother. While this mental and psychical electrotyping takes place automatically, the mothers brain and nerve molding power can be greatly strengthened and intensified by the **conscious** and **voluntary** operation of the psychical wireless that establishes vibratory oneness between her and the human entity in process of development within her own body.

Thus it is revealed how a brain prenatally refined, organized and fashioned may endow the nascent individuality with certain aptitudes and talents along established paths of cerebration. There surely will be less resistance along such lines of physical, mental and moral endeavor than along other lines not prenatally influenced and molded. Therefore I strongly advise mothers, pregnant with new life holding marvelous possibilities for good or evil, not to be influenced by the superficial reasoning of materialistic science, but to follow the sacred intuition and impulse of their own creative genius in this, the most holy function of their being. Every normally constituted mother is intuitively aware of this wonderful power, and is willing and anxious to exercise it when her consciousness has been aroused to the great possibilities and responsibilities which the divine privilege of motherhood confers upon her.

It is natural for us to admire a great artist who portrays the human form, true to life, on the painted canvas, or who fashions it from inanimate stone, metal or marble; how much more grand and godlike is the creative power of truly mated parents whose privilege it is to bring into the world, and to fashion according to their highest ideals, a human being endowed with life and intelligence, with the infinite possibilities of a **new center of creative activity**.

Yet many mothers, totally ignorant of their divine creative privileges and possibilities, victims of physically and morally degrading marriage relations, and often filled with secret aversion or open hatred for their marital companions, pass unwillingly through pregnancy and not infrequently seek to destroy the new life. When the unfortunate victim of such marital incompatibility, conceived in passion and developing under the worst possible influences of mental and emotional discord, comes to arouse the maternal instincts of affection and devotion, then fear, anxiety and worry, like a continual nightmare, haunt the unhappy mind of the mother and impress their discordant vibrations upon the sensitive films of infant consciousness.

Compare this condition of fear, apprehension and gloom in the mind and soul of an unhappy and unwilling mother, with the joyful and ecstatic state of mind of a mother conscious of
the creative power of her intelligent will, who, from the time of mating and procreation, with accurate prescience prepares the most favorable conditions, astrologically, prenatally and postnatally for the finest development of the physical, mental and moral characteristics of the future world citizen.

The loftiest exaltation of a creative genius working in dead clay and cold marble cannot approach the ecstasy of a mother who has acquired a knowledge of the great laws which make possible the development of a perfect human being, the embryo of a master, an angel, a being destined to be godlike in its faculties, capacities and powers!

In place of fear and anguish of soul, what joy to the mother who knows that it lies within her power to prevent disease and degeneracy in her offspring; that the development of the child depends solely upon her own intelligent effort! Nothing is left to accident. Child bearing becomes an exact science, the most beautiful and inspiring of all arts and professions. Under such conditions motherhood, instead of being the greatest of hazards and hardships, becomes a divine privilege and the highest achievement of human existence and endeavor. It falls short only of the creative work of the great Universal Intelligence whose instrument of creation is the mother.

2. An Example from History. Let us consider the oft-quoted example of Napoleon Bonaparte. His mother, Lutitia Bonaparte, while pregnant with the future military genius, accompanied her husband on a military expedition, sharing with him the hardships and excitement of camp life, and the marches and battles of a military campaign. If there be nothing in prenatal influence, is it not singular that Napoleon should have become one of the greatest military geniuses of all ages, while not one of his many brothers ever exhibited enough military ability to make an efficient corporal? What was it that favored or determined the birth of the great military prodigy under these circumstances? The ancestors of Napoleon's father were not professional soldiers, nor was the father especially interested in military matters before the conception of his gifted offspring.

The dominant influences, therefore, must have operated through the singular occupation and surroundings of the mother during this particular pregnancy.

Many similar striking examples have been cited in works on prenatal influence. I myself might add many convincing proofs from an extensive experience in medical practice; but time and space do not permit. Contributory evidence may be secured from many excellent works dealing with this vital problem in human life. I may be permitted to say that use heredity and prenatal influence are distinctly manifest in the physical and mental characteristics of our three children who were born at intervals of seven and five years. Each one of them clearly mirrors in his or her physical, mental and emotional peculiarities the predominant mental tendencies, occupation and surroundings of the parents during the
respective prenatal periods. Similar manifestations of prenatal influence may be observed in almost any family.

3. Birthmarks. Medical men of late deny also the possibility of "marking" the offspring by sudden fear or shock on the part of the mother during pregnancy. Incidents of this kind, however, are of such common occurrence that it is a waste of time to refute these flippant denials.

There are good reasons for believing that such marking is more likely to occur during the periods when the menstrual flow should take place, but is suspended.

It may be argued that to mention the possibility of marking to a pregnant woman will greatly increase the probability of electrotyping violent emotions upon her offspring; in other words, that the fear of the thing will help to materialize it. This may be true to a certain extent, but we must remember that sudden shock through fear or disgust may cause the mischief anyway, whether or not the expectant mother is aware of the possibility. Understanding a danger and being prepared for it seems the best protection. The pregnant woman should study carefully section XXX, dealing with mental and emotional causes of nervous diseases, and should learn to relax to any sudden surprise and thus neutralize unpleasant and fear arousing impressions. Self-control is the royal remedy and the key to mastership.

4. Physical Influence. Now that we have studied some of the more important hereditary mental and psychical prenatal and postnatal influences, let us see how the physical condition of the mother's organism influences the brain and nerve matter of the fetus in its last stages of development, and after birth.

Materialistic science teaches that brain matter exudes thoughts and feelings, as the liver excretes bile, or the stomach pepsin. Natural science proves that mind is superior to matter, that the new born ego, by the power of intelligent volition, must fashion in the gray matter of the brain the molecular groupings or centers for the expression of intellectual and emotional activities, such as language, music, numbers, scientific and philosophic speculation.

This means that active cerebration and brain molding do not begin until after birth. But it stands to reason that the work of the nascent intelligence may be greatly facilitated or impeded by the physical condition of the brain. It is reasonable to assume that intellectual and emotional vibrations will more easily shape the gray matter of the brain into new configurations when it has been prenatally refined, organized and developed along certain lines of cerebration by use heredity and by constructive prenatal influences.

There exists a remarkable similarity between the brain molding and memory building activities of the intelligent ego and the making of phonographic records and moving picture
films. Lifelike impressions of sounds and passing scenes can be made upon the phonographic and photographic mediums only when wax and film are in a highly refined and plastic condition. When impure of substance and coarse of texture they, are not sensitive and plastic enough to register and retain the subtle and highly complex vibrations of sounds and passing scenes. In order to receive and register a great variety and complexity of sounds, the wax on the phonograph cylinder must possess a certain degree of refinement, softness and plasticity. If it is too hard and coarse it registers the loud and coarse sounds only. Such a record cylinder, exposed to a beautiful symphony executed by a great orchestra, would register and reproduce only the shrill cries of the trumpet, the rattle of the snare drum and the booming of the big horns and bass drums. The softer sounds of string, wood and wind instruments and finer shadings of tone and rhythm would be lost. With increasing refinement and plasticity, more subtle and delicate sound vibrations will be retained and reproduced.

In like manner the sensitive gray matter of the cortex of the brain must be in a pure and plastic condition in order to receive and register the impressions and impulses coming through the sensory organs, the psychic intuition and the intellectual and emotional activities of the mind. Anything in the way of physical impurity or foreign matter that tends to clog the brain, or to feed it with waste and morbid materials, or with corroding poisons, will lessen the atomic and molecular motility of brain and nerve matter, and will interfere with, or impede, the groupings and subtle transformations involved in the fashioning of brain centers through mental and emotional influences.

If the nutrient blood which feeds the brain substance of the fetus be saturated with CO₂, the benumbing, paralyzing carbon-dioxide, with clogging uric acid or the destructive acids of phosphorus and sulfur, the gray matter cannot, respond to the subtle and complex impressions and impulses from without and within.

The purity or impurity of the plastic matrix of the cortex depends upon the materials absorbed from food and drink. If these are so constituted as to create in the system excessive amounts of clogging and corroding substances, then these food and drink poisons will have a benumbing and deteriorating effect upon the sensitive gray matter of the brain, as well as upon the coarser tissues in the joints, muscles and vital organs. There is a rheumatism of the mind as well as of the joints.

A brain asphyxiated and clogged with pathogenic materials cannot be alert and active; it is too dull and lazy to think; it would much rather sleep than work; it is incapable of doing its best when its tiny blood and lymph vessels are obstructed with waste and morbid deposits which prevent the oxygenation and drainage of its delicately organized cellular tissues.
This, of course, is true postnatally as well as prenatally. A brain originally capable of the highest and finest achievements of the human mind may become utterly worthless, and may degenerate into idiocy through food, drink and drug poisoning.

Medical men tell mothers they need not worry over prenatal feeding, because the placenta, the vascular bag which forms the nest of the new life, acts as a filter which purifies the blood before it reaches the fetus. Common sense and every day experience tell another story. Even the best in the blood of many mothers is bad enough to serve as food for the new life.

The placenta does not filter out of the blood of the mother all food, disease and drug poisons. This is proved by the wretched condition of many infants, suffering from malnutrition, anemia and rachitis, after delivery. If the vital fluids of the mother are deficient in the mineral elements, or in other important nutritive substances, how can they deliver them to the fetus?

Occurrences like the following, quite common in our institutional practice, prove positively that the placenta is not a perfect filter for systemic poisons and for disease taints circulating in the blood of the mother.

One of the most pitiable cases of eczema in a little child less than one year old we traced to the fact that the mother, during her first year of marriage, had traveled with her husband through Eastern European and Asiatic countries, and during her pregnancy had been vaccinated five times while passing through localities where smallpox was prevalent. Both she and her husband had always enjoyed perfect health. The family record was excellent as far as traceable; still the body of the infant soon after birth, was covered with open bleeding sores, presenting a revolting sight. We could find no explanation for this strange phenomenon other than the many vaccinations during pregnancy. These had contaminated the blood of the mother, and through her the body of the fetus, with a filthy scrofulous taint.

The baby suffered terribly. For many months it slept but little, because of the excruciating pains. The eczematous eruptions were of a very stubborn nature; they broke forth again and again. Finally, however, after eighteen months of natural treatment, we succeeded in purifying the little body of the horrible infection. The child is now a little over three years old, in perfect health, and during the last twelve months has shown no signs of the morbid taint.

Under another section I shall describe the influence of food upon character and sex life.

To recapitulate: Purity, plasticity and motility of the highly refined and sensitive materials which make up the gray matter of the brain depend upon pure food, plenty of fresh air and exercise, and upon all other natural methods of living.
SECTION XXXV

Conception and Pregnancy

1. Conception takes place whenever the male spermatozoon joins the female ovum (egg) within the woman's womb. Normally the female organism liberates from its ovaries but one ovum each month, usually during menstruation, while the male discharges millions of spermatozoa at each orgasm.

Conception does not always follow copulation. The ovum remains in the womb and is capable of impregnation for about five days after menstruation. The spermatozoon on entering the womb may meet an ovum which has been discharged at a previous menstruation, or it may remain alive in the womb for a number of days and finally come in contact with a newly discharged ovum at the following menstruation.

The spermatozoon retains its ability to impregnate the ovum for from ten to fifteen days after its discharge into the womb. When the male and female germs merge into one another, conception or impregnation takes place. As soon as this has happened, the impregnated ovum becomes attached to the inner lining or mucous membrane of the womb and begins its new life as an embryo. The period comprising the time from the impregnation of the ovum until the beginning of labor or childbirth is called pregnancy.

The table of pregnancy on page 377 indicates the probable date of normal termination of a pregnancy, calculated from the last menstruation.

2. Exercise During Pregnancy. Unfortunately a great many expectant mothers labor under the idea that they must rest and be relieved from work and exercise. This of course is a great mistake. Light housework is good exercise. There is nothing more harmful during pregnancy than nursing "that tired feeling" by lounging idly about the house and coddling one's real or imaginary aches and troubles.

Of great benefit to the pregnant woman are all outdoor sports such as tennis, golf and other games which require vigorous exercise without straining or overworking the body. The great benefit of walking and other outdoor exercises, aside from their general invigorating effects, lies in the strengthening of the abdominal muscles and ligaments, which at delivery will greatly facilitate expulsion of the fetus.

The walk should be brisk and rhythmical, body erect, head thrown back, chest forward; the breathing at the same time should be deep and regular. These walks should be continued as long as time and endurance permit. Nothing, of course,
must be pushed to the point of exhaustion. One good long walk every day is necessary; two are better.

We all understand the necessity for a plentiful supply of oxygen under ordinary conditions, and especially in time of illness. During pregnancy the demand for oxygen, as well as for mineral salts, is doubled or trebled on account of the needs of the rapidly developing organism in the womb of the mother.

These extra demands for oxygen and ozone must be supplied by systematic deep breathing, cold bathing, outdoor walks, etc. If circumstances do not permit the taking of outdoor exercise, deep breathing should be practiced as often as feasible, at the open window.

Next in importance among gymnastic exercises is the internal massage described under section XXI, No.16.

Those exercises are especially valuable which bring into play the abdominal muscles and the muscles and ligaments of the genital organs.

3. Clothing. Clothing and the manner of wearing it profoundly influences the normal or abnormal development of the fetus, the health of the mother, labor and delivery.

At no time should the waistline be constricted by a corset or even by the ordinary skirt band. All clothing should be as loose and light as possible—one-piece under and outer garments, with the weight suspended from the shoulders, are best. If skirts are worn they should be fastened to skeleton waists of some thin cotton material. The close, heavy texture of the material from which the corset or so called "reform waist" is made is injurious because it interferes with skin elimination.

Even the slightest constriction of the waist line interferes with the free circulation and the normal blood supply to the abdominal organs, which is of especial importance in pregnancy; it also hinders the free expansion and movement of the uterus during the various stages of pregnancy.

Within the waistline are located a dozen or more important vital organs of the body. Any sort of constriction compresses these organs and pushes them out of their normal position. While this is extremely injurious to the body of a woman under ordinary conditions, it is doubly so to the pregnant mother and to the rapidly growing fetus. Undoubtedly many deformities and monstrosities are produced by unnatural constriction of the blood vessels and vital organs in the abdomen and pelvis of the pregnant woman.

If due attention is paid to the foregoing influences, labor and delivery will be brief and easy. This we have proved in hundreds of cases which have come under our management. The reason why women of civilized countries spend many
hours and sometimes days in dreadful agony of childbirth
while those of primitive or savage races, as we call them,
produce their young easily and painlessly as the animals do, is
that primitive women live more simple and natural lives,
while "civilized" mothers violate practically every law of
Nature in their daily habits of living.

Civilization unfortunately stands in many respects for that
which is artificial, unnatural and therefore productive of
disease and suffering in all domains of life, not only as regards
physical health, but social and political health as well.

SECTION XXXVI
Danger Signs During Pregnancy

1. Dropsical Swelling. Swelling of the limbs and distention
of the veins of the legs during pregnancy may be caused by a
tendency towards varicosity, intensified by obstruction of the
circulation due to the enlarged uterus. Such a condition
requires, aside from the natural regimen, careful and
competent treatment.

Swelling of the limbs or other parts of the body may also be
caused by incipient or advanced Bright's disease. The urine
should be examined from time to time, especially if there is a
swelling of the feet and ankles, or if there are dropsical
symptoms in other parts of the body.

Such dangerous conditions are usually brought about
through the excessive intake of starchy and protein foods
which overwork the liver and kidneys and cause pathogenic
dogging of the capillary circulation. This may result in uremia
attended by violent and sometimes fatal Convulsions.

2. Uremia is the result of retention in the system of waste
materials and poisons that should be eliminated through the
kidneys and skin. Medical treatment for such conditions, aside
from the administration of stimulating drags, consists in hot
bathing with the idea of opening the pores of the skin.

We understand that all hot water treatment gives only
temporary relief and is followed by greater enervation and
inactivity of the skin. The best water treatment for systemic
poisoning of any kind consists in the application of wet packs
followed by cold ablutions as described in section XV.

The addition to the packs, dry friction rubs, air bath, good
massage and neurotherapy treatment will aid in restoring the
normal activity of skin, bowels and kidneys.

Whenever the urine contains sugar or albumen, fasting,
alternating with raw food diet, is indicated. Suitable regimens
are outlined in sections X, XI.
The giving of heavy food to the mother with the idea of increasing the flow of milk is all-wrong. We have found in all cases that the diet outlined in section X will produce a more copious flow of rich milk than lie "nourishing" meat diet. The best remedy for a scanty flow of milk is slow and thorough mastication of a few spoonfuls of raw crushed wheat every day.

3. Morning Sickness. One of the common disorders experienced during pregnancy is that known as Morning Sickness. One suffering from this ailment, though following a natural diet, should sip a cup of hot postum while remaining in bed. If this does not have the desired effect and if the patient has not been accustomed to drinking coffee, half a cup of black coffee with a few drops of lemon juice will quiet the irritated nerves. It is necessary after taking the hot drink to remain in bed for at least thirty minutes. It is understood that this is only an emergency measure. If continued, it will lose its good effect and work injury.

SECTION XXXVII

Labor and Delivery

At about forty weeks, exactly nine solar months, from the period of conception the fetus reaches full maturity, and labor begins. Labor is divided into three stages. During the first stage the neck of the womb becomes slowly and gradually distended and the orifice of the womb opens widely. When this has taken place, the fetal membranes burst and the amniotic liquid surrounding the fetus escapes.

During the second stage the fetus emerges from the womb.

After expulsion of the fetus, the placenta is expelled from the uterine cavity. This constitutes the third stage of labor.

The first stage usually begins with more or less radiating pains in the abdomen, accompanied by dull pain in the small of the back and a drawing pain in the limbs. Sometimes women with the first baby feel these pains weeks in advance of the actual commencement of labor. At first they occur at long intervals and are of short duration, but gradually become more prolonged and more frequent. The pains are due to a cramp-like contraction of the muscular apparatus of the uterus forcing its contents downward.

Under this pressure from above, the neck and mouth of the uterus distend to their limits, and the walls become thinner and thinner. First the inner, then the outer orifice of the neck of the womb opens and the fetal membranes protrude and finally rupture, allowing the amniotic fluid to escape. Shortly after this the part of the fetus nearest the orifice, normally the
head, makes its appearance. At the present time the average duration of the first stage of labor is six hours, but it may last twenty-four hours or longer, depending upon the plasticity and elasticity of the bony structures of mother and infant, the rigidity of the cervix, and the vigor or lack of vigor of the muscular apparatus of the uterus.

While the foregoing is true of the average delivery under ordinary ways of living, we find that after the enforcement of a natural regimen of living during and, better still, before pregnancy, the entire period of labor and delivery does not cover more than half an hour, or at the utmost from one to two hours. Even the disadvantages of slight build and smallness of pelvis can be overcome by the natural regimen outlined in section X. When our youngest child was born, the mother gave the first sign of pain at about midnight. I rose from bed instantly, but had not time to finish clothing when the membranes broke. Within twenty minutes after the commencement of labor the infant was resting in my hands.

The wife of a prominent lawyer in a western city had experienced three difficult deliveries. Each time surgical instruments had to be used and she had suffered untold agonies lasting from 24 to 36 hours. When she became pregnant the fourth time the most prominent physicians in her home city assured husband and wife that it was not safe for her to go through another delivery, that the womb was in worse condition than ever before therefore they recommended surgical removal. For conscientious reasons, however, the husband and wife did not follow the advice of the doctors, but decided to try natural methods of treatment.

The lady placed herself under our care during the fifth month of pregnancy. From that time on she followed strictly the natural regimen of living and received daily the usual hydropathic and manipulative treatments. This was continued until a few weeks before delivery. In this case the baby was born within an hour from the first contraction, and the mother of the patient, who was in an adjoining room, had not heard a sound. Many similar experiences refute the idea that it is unsafe and injurious for pregnant women to undergo the ordinary methods of natural treatment, such as hydropathic sprays, sitz baths, massage, Swedish movement and other forms of manipulation.

1. Preparation for Delivery. The diet during the last week before the beginning of labor should be very light, consisting mostly of fruits and vegetables. From the commencement of labor no food at all should be given, until at least twenty-four hours after delivery; a three-day fast is better.

In addition to a competent physician, a nurse or midwife should be engaged. If a good neurotherapist, who has had sufficient experience in obstetrical work, can be procured, he should be preferred, because he can assist delivery and make it much easier by manipulative treatment.
The nurse will make the necessary preparations and provide the various supplies needed in labor. With the first sign of approaching labor, the physician in charge should be summoned. A rectal enema of one pint or more of warm salt water (See. XVIII, No.4) should be administered. The woman should be given a vigorous cold rub and her genitals thoroughly cleansed. She may then remain on her feet and walk about, comfortably dressed, until actual labor commences.

2. No Anesthetics. The attending physician should not be impatient to hasten delivery with drugs or instruments. The use of anesthetics should be avoided insofar as this is possible. They should be employed only when absolutely necessary—that is, when excessive pain must be allayed or when surgical delivery is unavoidable.

3. Breaking of Water Bag. When the bag of water is about ready to break, the patient is placed in bed. Premature discharge of the amniotic fluid must be guarded against. An escape of the liquid at an early stage means difficult and prolonged labor, commonly known as "dry labor". Usually the membranes burst when the orifice is fully dilated. A large sponge is held in readiness to catch the out-flowing liquid.

3 a. Umbilical Cord. When the infant has been delivered, the umbilical cord should not be severed at once. Plenty of time should be allowed for the blood to transfuse itself from the body of the mother to that of the child. This is important. If the connection is severed too soon, the child begins life in an anemic condition.

The newborn baby usually greets the world with a lusty cry. It should be placed on its right side with its face turned away from the mother, care being taken that the cord is not stretched tight. As soon as the cord stops pulsating, plenty of time being allowed for blood transfusion, it is tied about two inches away from the baby's abdomen and cut a little above the ligature. The baby is now wrapped in a warm blanket and put in its crib.

4. After Delivery. Immediately after the baby is born, the nurse or attending physician gently compresses the abdomen and womb of the mother, kneading and rubbing it occasionally in order to secure complete contraction and thus prevent hemorrhage. After delivery the mother enjoys a period of rest and recuperation which usually lasts for about half an hour.

5. Afterbirth. Meanwhile the placenta becomes detached, and when the pains set in again a few contractions usually suffice to expel it with all the membranes.

The attending physician must make sure that none of it is left in the body, since this might result in putrefaction of the remains and blood poisoning. The woman's genitals should be washed with clean sterilized water.
The exhausted woman should now enjoy a deep, wholesome sleep and awaken from it in a few hours refreshed and strengthened.

In the foregoing I have not gone into the details of obstetrics and of technical management because this must be left to a competent obstetrician. I have called attention only to those points which are of special importance from the viewpoint of Natural Therapeutics and to the differences in treatment between the conventional and natural methods.

6. The Lying-In Period. The lying-in period varies from five to twelve days, according to the constitution of the mother and the care that she has taken during pregnancy. The greatest danger of the lying-in period is puerperal sepsis or blood poisoning. This condition is the result of infection occurring during labor, or it may result from the retention of parts of the placenta.

The only way to prevent this is by observing the most scrupulous cleanliness during the entire process of childbirth and during the lying-in period. When blood poisoning has developed it must be treated the same as all other acute inflammatory diseases (see section IX).

7. Care of the Newborn. The child should begin to breathe immediately after the cord is cut. If it fails to do this, the physician should lift the baby by its feet to facilitate the escape of mucous from the trachea and throat. If necessary the mucous must be removed from the throat by the insertion of the little finger, or by means of a tiny stick covered with gauze.

Breathing may be accelerated effectively by a few sharp taps on shoulders and buttocks. If this fails to bring the desired result, artificial respiration must be resorted to at once. The attendant grasps the child by its shoulders, its head resting between his palms and the two index fingers being hooked under the child's armpits. It is now swung between the physician's legs and lifted high above his head so as to be turned upside down. This is repeated from fifteen to twenty times, after which it is placed in a basin containing a few inches of warm water. Its body should then be rubbed briskly with cold water.

Father Kneipp used to take the newborn babe by the nape of the neck and the feet and submerge it quickly in cold water. This, a few times repeated, is probably the quickest way of resuscitating an asphyxiated baby.

In order to soften the cheesy deposit which frequently covers the body of the newborn, it is well to rub the skin with warm olive oil. After the greasy covering has sufficiently softened it may be removed with bits of gauze. This is followed by a cleansing bath with warm water and castile soap.
After the warm cleansing bath, the little body should be quickly rubbed down with cold water, wrapped in a soft, warm blanket and laid away to sleep until it wakes of its own accord. A normal baby should sleep for about twelve hours, and must not be disturbed to force food on it before it is ready to take it.

8. Bathing. From the first day, the baby must have a morning and evening bath. This consists, as before described, in a quick, cleansing bath of warm water and castile soap, followed immediately by a brisk cold rub. In the course of a few weeks the baby can be placed, for the cleansing bath, in a small bathtub containing a few inches of warm water. Immediately after the cleansing bath the warm water is replaced by cold water. This is taken up in the hollow of the hand and briskly applied to the little body. In this fashion the child, within a few months time, will enjoy its cold rub just as much as an adult. I have seen several such nature cure babies, but a few months old, object most vigorously to a warm bath. The cold rub is the best preventive of chilling; but care must be taken that the temperature of the room where the bath is given is not below 70 deg.

The olive oil bath or rub, often recommended for premature babies or infants suffering from malnutrition, is very injurious, because it occludes the pores of the skin and prevents the elimination of poisonous gases and other morbid materials from the body. The skin is not an organ of digestion. Olive oil, like all other foods, must enter the body through the alimentary canal where, under the action of digestive ferments, it is broken down into its component elements which are then assimilated through the intestinal membranes. Oil absorbed through the skin is not digested, and it circulates in the body as foreign matter which in this state cannot be assimilated and utilized in the system.

9. Powdering after the bath is fully as injurious as the rubbing with oils or massage creams. Powders and creams tend to clog the pores, and most of them contain poisonous antiseptics which lower the vitality of the skin and prevent or suppress elimination in the form of skin eruptions, eczemas, etc. For chafing use nothing but cold water. In case the chafing should become unusually severe and painful, through neglect by the caretaker, a soothing and healing lotion composed of one part lemon juice to two parts olive oil, may be applied a few times, until the irritation is under control.

10. Air Baths. Next to cold water, there is nothing that will invigorate baby's skin and nervous system as will the air and sun bath. If the season will not allow the outdoor air bath, the baby should be allowed to lie nude several times a day, for thirty minutes or more, in a warm, well ventilated and sunny room.

11. Constipation. Glycerin and suppositories should never be used; neither laxatives nor cathartics. Oat extract and cooling sitz baths will produce natural movements.
12. **Diarrhea** is a form of morbid elimination, and must never be suppressed by drugs. If it is habitual, bailey or wheat extract prepared in the same manner as oat extract, is a good remedy. If the diarrhea is persistent and of a violent nature, no food at all must be given, except water with dilute acid fruit juices, until the purging ceases. Even then plenty of time must be allowed for the rebuilding of the sloughed intestinal membranes.

13. **Bandages.** Until the umbilical cord dries up and falls off, it is necessary to cover the navel with a gauze compress dipped in olive oil. This is held in place by an abdominal bandage made of soft cotton material. These strips should not be hemmed, merely torn or cut. They should be drawn just snugly enough to hold the compress in place, but not tightly enough to interfere with circulation. The, navel must be cleansed and the compress renewed twice each day. After the umbilical cord has dropped off we no longer apply the abdominal bandage. This is contrary to common usage, but is the best practice. The abdominal bandage overheats the body and interferes with the free movement of the diaphragm and the circulation of the blood.

14. **Clothing.** The clothing of the infant should be loose and light and as simple as possible. Freedom of movement is very important; binding or pressure upon any part cannot help but interfere with the circulation, and otherwise produce injurious results. The clothes should be short, in order to allow the feet and legs free play. Light weight, porous cotton materials are best for both under and outer garments. A lightweight wool petticoat may be worn when absolutely necessary to provide sufficient protection for the baby. Cotton hose and bootees may be used, but under no circumstances should such articles be of wool, because it prevents free elimination from the skin. The baby's head should not be covered out of doors, except in severe weather. At no time should a veil be placed over the face, as it will cause the infant to reabsorb the poisonous exhalations from its own lungs. All clothing should be changed each day. No garment should be starched—such a practice is not only useless but harmful.

15. **Diapers** must be provided in sufficient number to allow thorough cleansing and drying. The wet diapers should be scalded in hot water and very thoroughly rinsed in several waters afterwards. They should then be dried in the open air and sunshine. Soiled diapers must be well washed and boiled. Washing powders, soda, ammonia and other chemicals should never be used. They have an extremely irritating effect upon the delicate skin of a baby. In order to save labor and to facilitate the cleansing of the diapers, small squares of clean old linen or muslin rags, or pieces of absorbent gauze, may be placed inside. These inserts will absorb all or most of the bowel movement and may then be burned. If the skin is irritated or chafed, the parts should be sponged off with clean cold water at each change, paying special attention to cleansing of the genitals. Oils or powders must not be used to soothe the sore places, because they clog the pores and
Interfere with natural elimination.

16. A wet nurse is to be preferred to artificial feeding. She should be thoroughly healthy, not over thirty years of age, of equable temper, not excitable or nervous and her diet should be that prescribed for the mother.

17. Care of the Nipples. They should be thoroughly cleansed before and after nursing; not with carbolic acid, but with water and dilute lemon juice. The lemon juice tends also to harden the nipples. Treatment of the nipples may begin before the birth of the child.

18. Care of the Eyes. The baby's eyes, whether awake or asleep, should always be shielded from strong light, either sun or artificial, and from dust and wind. The eyes should be washed with cold water after every cleansing bath. If they show any tendency to weakness or disease, slight vibratory massage over the closed eyelids should be given after the cold eye bath.

19. Care of the Mouth. A healthy baby's mouth needs no cleaning before the arrival of teeth. As a matter of fact, the teeth of a perfectly healthy adult would not need cleaning any more than those of an animal living in the freedom of nature. The saliva is a sterilizing fluid, under normal living, intended by Nature to keep the mouth clean and healthy. Cleansing of the mouth of an infant with the finger or with a cloth may injure its delicate membranes. If the mouth must be washed, in case of disease, a swab made by twisting a piece of sterilized absorbent cotton on the end of a smooth stick should be used. The swab should be dipped in warm boiled water, and the interior of the mouth washed thoroughly, the cotton then being burned.

20. Care of the Ears. The external ear should be cleansed with a soft rag or swab as before described. Never use a hard instrument inside the ear.

21. Care of the Nose. A baby's nose should be cleansed as a part of the daily toilet, in the same way as the ears. A swab may be made by twisting a piece of gauze to a cone. As soon as the child becomes old enough, it should be taught to sniff up cold water through the nostrils and the nasal passages. This is the best way to keep the nasal membranes in a clean, healthy condition.

22. Care of the Genital Organs. The genital organs of both sexes must be kept scrupulously clean with as little handling as possible. The foreskin of the penis of the male baby should be drawn back at bathing time and the organ thoroughly cleansed, always finishing with cold water.

23. Phimosis. The treatment of phimosis is fully described under Sec. XXVIII, No. 1.

24. How to Lift the Baby. The best way to lift a young
baby is to slip the left hand under the back beneath the shoulder, spreading out the fingers in such a way as to support the neck and head. Then lift the feet and legs with the right hand. **Never lift an infant without first supporting the spine.**

When a baby has grown strong enough to hold up its head and has gained considerable strength in the muscles of the back and neck, he may be lifted by grasping him with outspread fingers under the armpits; the body must be held firmly so that the entire strain does not come on the shoulders. A baby should never be lifted by the arms. This may dislocate the shoulder joints.

SECTION XXXVIII

Prenatal Feeding

1. Effects of Diet During Pregnancy. The problem of infant nutrition begins before birth. Prenatal feeding determines the physical start in life. On it depends not only the condition of the mother's health during pregnancy, but also the size and weight of the fetus, pliability of the bony structures, ease or difficulty of delivery, and the quality of the mother's milk.

   The fleshier and heavier the newborn infant, the prouder and happier are the parents and the doctor. Yet, excessive size and weight of the child constitute the most prominent cause of difficult and painful childbirth and frequent necessity for instrumental delivery.

   The biblical saying, "In sorrow thou shalt bring forth children"; has led many to believe that woman's dreadful suffering is a necessity, God ordained; but is not man's ignorance, rather than the cruelty of an avenging God, to blame?

   This latter view is confirmed by the fact that other mammalia literally cast their young, without pain or difficulty; and the labor pains of primitive mothers are insignificant, their delivery presenting little more difficulty than that of the lower animals. A squaw on the Western Plains stops a few hours by the wayside to deliver her papoose and then resumes her journey as though nothing had happened.

   Women among the European peasantry, who wear no corsets, live on black bread and vegetables, and have plenty of exercise in the fields and in the home to the last day of pregnancy, have their babies without help of midwife or physician and resume their usual routine of work within a few days after delivery.

   Thousands of mothers who have adopted natural ways of
living have learned to dispense with anesthetics and the surgeon's instruments; they now bring forth their offspring without excessive pain.

2. Results of Faulty Diet. It is significant that the offspring of the lower animals, at birth, consist of little more than skin and bones, while the newborn human is often abnormally large and fat. This is especially true of babies born of weak and anemic mothers. As before stated, excessive size and weight of the infant is not a matter for congratulation, but is a pathological condition. It indicates fatty degeneration of the fetus, due to the anemic watery condition of the blood of the mother, and the cause of this hydremia of mother and child lies in the faulty dietetic habits of the former.

The ordinary diet of American women consists almost entirely of meat, fish, fowl, potatoes, white bread, pastry, coffee, tea and refined white sugar. The few vegetable, which enter into the daily dietary are first deprived of their all important organic salts by faulty cooking; fruits are looked upon as luxuries and frequently are regarded as harmful.

The anemic, watery condition of the blood of mother and child is not due to a lack of starchy, protein and fatty materials in food and blood, but to a deficiency of organic mineral elements. Neither is the anemic condition, as the regular school of medicine assumes, caused by lack of iron. Any ordinary food mixture, as well as the blood and milk of anemic mothers, usually contains a sufficient amount of iron. The actual cause of the anemia is a deficiency of other mineral elements.

As I have explained in Volume III of this Series, carbonic acid poisoning and the resulting sluggishness of the surface circulation, coldness of the extremities and congestion of the inner organs is not caused so much by a lack of the oxygen-carrying iron as by a deficiency of the carbonic acid neutralizing and eliminating sodium and magnesium.

If the blood is deficient in lime, phosphates, silicon and fluorine, rachitic conditions, softening of the bones, deformed spines and legs, and decay of the teeth, are inevitable results.

It is an easy matter to supply the daily needs of the organism for proteids, starches, fats and sugars; the difficulty lies in supplying a sufficient amount of the organic mineral elements.

The deficiency of sodium in human blood, Dr. Lahmann proved in the following table of comparative blood analyses. In a hundred parts of ash he found in the

<table>

Blood of dogs | 2.02 to 5.78
Human blood | 2.03 to 6.27

The percentages of lime and of other positive mineral elements in the human blood are also much lower than in the blood of cows, oxen and sheep.

While the blood of cattle and sheep raised on pasture is very uniform in composition, hardly any two samples of human blood are alike. It is for this reason that Dr. Lahmann adopted cow's milk instead of human milk as the standard elementary food combination.

In the following table, he compares the percentages of minerals in the ash of cow's milk with the percentages of mineral elements in the ash of various other food materials.

A daily dietary consisting largely of meats, eggs, white bread, potatoes, peas and beans, though excessively rich in proteids, fats and starches, will, on account of its deficiency in sodium, lime and magnesium, inevitably result in carbonic acid poisoning, anemia, rachitis, premature decay of the teeth and a multitude of other acute and chronic ailments.

If, however, the daily dietary contains a liberal amount of green vegetables and fruits, a normal food mixture resembling that of cow's milk can easily be obtained. It must be remembered that fruits and vegetables are not only rich in the most important mineral salts, but that they are relatively poor in proteids and carbohydrates.

For this reason fruits and vegetables facilitate the establishment of an equilibrium between proteids and carbohydrates on the one hand and organic mineral salts on the other.

3. Excessive Fat Formation. We can now understand why the ordinary faulty diet of pregnant mothers causes anemia, softening of the bones, sluggish circulation, carbonic acid poisoning and fatty degeneration in mother and offspring.

Lack of sodium causes excessive accumulation of carbonic acid, and oxygen starvation. This results in defective
oxidation of food and waste materials; in other words, in fat formation.

Defective draft prevents the complete consumption of coal, and chokes the furnace with the products of imperfect combustion. Similarly, lack of oxygen in the tissues (due to carbonic acid poisoning) causes an incomplete combustion of food materials and waste products, resulting in fat formation and in the generation of poisonous byproducts.

Lack of sodium also prevents the neutralization and elimination of uric and other acids and ptomaines (pathogenic matter) which accumulate in the tissues, block the circulation and assist in the smothering of the vital processes.

In order to eliminate these pathogenic materials, there arises an abnormal craving for water—"the anemic thirst"—which is closely related to the thirst of fever patients and of diabetics. Excessive water drinking is encouraged by the popular "flushing" fad.

To make things worse, the anemic, for reasons before stated, usually suffers from weak heart action and sluggish circulation. This means defective elimination of water through the skin and kidneys, resulting in a watery (dropsical) condition of the tissues and fatty degeneration.

Not all anemic, carbonic-acid-poisoned mothers, however, develop a tendency to obesity. On the contrary, under certain constitutional conditions, they may become exceedingly lean, like the anemic, carbonic-acid-poisoned consumptive. Briefly stated, sluggish heart action and weak kidneys favor retention of carbonic acid and water in the tissues and thus make for fatty degeneration. Good circulation and normal activity of the kidneys may keep the system free from excess of water and carbonic acid, but excessive proteids in the diet may result in sulfuric and phosphoric acid poisoning. These destructive acids break down the tissues, rob them of their mineral constituents, and thus cause excessive loss of flesh and fat.

In both types of dysemia the blood of the pregnant mother is overloaded with poisonous gases, waste matter and the debris of broken-down tissues. The oxygen supply to the fetus is therefore very much impeded and we find that both fleshy and lean mothers produce babies of abnormal size and weight, ranging from eight to twelve pounds, while the normal weight of the newborn should not be more than six pounds.

4. Advantages of Natural Regimen. We know of many instances where mothers, after having given birth to heavy, fleshy babies, in subsequent births have reduced the weight of the new born to normal, and the pain of delivery to a minimum, by the adoption of a natural diet, plenty of exercise in the fresh air and systematic deep breathing.
The effects of a natural regimen are manifested in various other ways. The bony and muscular structures of mother and child are much more pliable and elastic, making parturition and delivery much easier. Pure blood, normal nutrition and abdominal exercises, walking and special gymnastics, greatly strengthen the abdominal and uterine muscles, thus facilitating expulsion of the fetus.

The morning cold rub, systematic deep breathing and general exercises, every day outdoor walks and right mental and emotional attitude are all of paramount importance in the regimen of pregnancy.

The Regimen for Wholesome Living, section I, is admirably adapted for all the needs of the pregnant mother.

SECTION XXXIX

Postnatal Feeding

Thanks to the educational influence of nature cure propaganda, a decided change for the better in baby feeding has taken place during the past ten years. Up to that time the "top cream mixture" was universally recommended by allopathic physicians and given to babies by trained nurses.

While in the meantime many physicians and nurses have adopted more natural methods, the "top cream mixture" is still too common and must be entirely abolished in order to safeguard the health of our little ones.

In the February, 1909, issue of the Nature Cure Magazine, I commented upon this subject as follows:

1. Bottle-fed Babies. Our food analyses disclose the interesting fact that the elementary composition of the ash of the milk of an animal is about the same as the composition of the ash of its body.

They also show that good cow's milk when normal comes closer to the requirements of the infant body than does inferior human milk.

Our tables of food analyses show that chemically the composition of cow's milk and of human milk is very much the same. Human milk contains a little less proteid and a little more sugar than cow's milk, and the latter is much richer in organic salts than the former. There is much more of the allimportant sodium in cow's milk than in human milk and about twice as much calcium (lime) and iron (table p.100). This explains why rachitis is so common among babies, while never found among calves.

As we have learned, the elimination of poisonous acids
from the body depends on sodium. The building of the bony structures depends on lime; the oxygenation of the blood, on iron.

Many years of practical experience in the care of babies has convinced me that milk fresh from a healthy cow is greatly to be preferred, as nourishment for infants, to the impoverished milk of scrofulous mothers.* In this connection it is significant that one-half of all "civilized" mothers, thanks to unnatural food and drink, vaccination and poisonous drugs, are incapacitated for nursing their offspring.

* This may not be true in the future if our milk cows continue to be regularly subjected to tuberculin tests.

To one who has studied the comparative analyses of cow's milk and human milk, it is incomprehensible why the former, when given to infants, should be diluted and spoiled by large quantities of water, salt, soda and inorganic mineral lime (in the form of lime water).

This procedure, however, is still frequently recommended by physicians of the regular school. Undoubtedly, the great frequency of anemic and rachitic diseases, the darkening of the iris, appearance of scurf rim, and the signs of catarrhal conditions in stomach and bowels are caused by such unnatural feeding.

The following extracts are taken from an article entitled "Bottle-fed Babies", in the Ladies' Home Journal. It was written by Dr. Emelyn Lincoln Coolidge, of the Babies' hospital, New York. Thousands of mothers, on account of the high standing and excellent reputation of this family journal, undoubtedly have followed, without question or misgiving, the advice presented.

The formulas given below are for the average healthy baby, and are called "cream" or "top milk" mixtures.

"Food for the first month. With a spoon, or a tiny dipper which comes for this purpose, carefully skim off the top six ounces from a quart bottle of milk; to this add twenty-four ounces of water which has been boiled and cooled, and in which has been dissolved three teaspoonfuls of granulated or six of milk sugar; next add a pinch of bicarbonate of soda and a small pinch of salt; mix this all thoroughly, and pour enough for each feeding into ten separate bottles. Then cork the bottles family with cotton and either Pasteurize the milk or stand it on the ice.

"For the second month. Skim off six ounces of cream, then pour off three ounces of milk; add twenty-four ounces of water and the same amount of sugar, salt and soda as above; mix and bottle.

"For the third and fourth months. Cream, six ounces; milk, six ounces; water, twelve ounces; barley or oatmeal gruel, twelve ounces; sugar, salt and soda as usual, etc.

**Plain Milk Formulas**

"Pour the entire quart of bottled milk out into a clean pitcher and then back into the bottle several times, thus thoroughly mixing the milk; then take:
"For the first month. Six ounces of milk, twenty-four ounces of barley-water, half a tablespoonful of granulated or one of milk sugar, a pinch of bicarbonate of soda; mix all well together and pour the proper number of ounces into separate bottles, and either Pasteurize or place on ice.

"For the second month. Nine ounces of milk, twenty-one ounces of barley-water, one tablespoonful of sugar, and a pinch of soda."

Physicians would never think of giving such advice as, this, if they were acquainted with natural dietetics founded on exact and complete analyses made by food chemists of the nature cure school.

I have already called attention to the fact that food chemistry, whether practiced in allopathic colleges, in great sanitariums or by vegetarian food reformers, deals with proteids, starches, fats and sugars only, and leaves entirely out of consideration the all important mineral elements or organic salts of potassium, sodium, iron, lime and magnesium.*

*This was true at the time this article was published in the Nature Cure Magazine.)

On these five positive mineral salts, as we have shown, depend all the important vital functions of the human organism, while proteids, starches, fats and sugars serve only as building and fuel material.

The digestion of the proteid and carbohydrate foods, as well as the elimination of the waste matter resulting there from, depends upon the positive organic mineral salts.

Study carefully these recipes for baby feeding, taken from the Ladies' Home Journal, and compare the mixtures with the analyses of cow's milk and human milk in the accompanying tables.

Let us consider the "top milk" mixture, prescribed for the first month. The cream rising to the top is almost pure fat. The all-important mineral elements plus the nourishing milk sugar and proteids remain in the skimmed milk, which is looked upon as worthless and fed to the pigs.

Our food analyses (see tables in Volume III, Cook Book) show that the ordinary brands of flour are almost devoid of mineral elements. Furthermore, one teaspoonful of barley to one pint of hot water does not mean much in food values. Where in these six ounces of cream (fat) and twenty-four ounces of barley water is baby to get the necessary amount of sugar for fuel material, of proteid for tissue-building, of lime for bone-building, of iron for oxygen-carrying, and of sodium, magnesium and potassium for the processes of elimination?

It seems that these deficiencies are intended to be overcome by baking soda, mineral table salt and the lime water, so generally prescribed by physicians. Many times I have demonstrated that inorganic mineral salts, with the possible exception of a little table salt, should not enter the animal or human organism, that these salts must first be organized,
made alive in the plant or animal cell, before they are wholesome food for animals or human beings. I have shown that, taken habitually in the mineral form, these salts accumulate in the human body, act as irritants and poisons and reveal their presence in the iris of the eye.

I fail to understand why the tender and sensitive organism of the newborn infant should be encumbered with inorganic minerals while cow's milk contains them in ideal form, made alive first in the grasses and grains, then still more highly organized and magnetized in the body of the animal.

It is bad enough to give mineral sodium, lime and table salt to an adult, but it is little short of criminal to give them to babies under the guise of foods and medicines.

The cream mixtures are readily digested, because there is not much to digest. The fact that infants thus fed cry for food continually is good evidence that their needs are not satisfied. Babies fed with this sort of slop grow fat for a while. The watery food inevitably produces fatty degeneration. This for a season swamps the little body with unhealthy fat. But the first crisis which happens along often takes away not only the unnatural fat, but the baby also.

The artificial mixtures contain entirely too much water in proportion to nourishing elements. The resulting malnutrition and the constant irritation caused by the inorganic minerals result in chronic diarrhea or constipation.

**The Right Way**

The best food for the newborn and growing infant is undoubtedly the mother's milk, provided that she is herself in fairly good health. Unfortunately, many mothers are unable to nurse their offspring, and if a healthy wet nurse cannot be secured, other food must be provided.

The best substitute for human milk, without question, is cow's milk, fresh, pure and undiluted, as it comes from the animal.

"Why", indignantly exclaims the trained nurse, when we give these instructions, "undiluted cow's milk is altogether too rich, it is indigestible for baby; if the milk is not boiled or pasteurized, germs and bacilli will surely create infectious diseases".

To this we answer: Our analyses show that the difference in composition between cow's milk and human milk is not enough to affect the infant. The danger lies not so much in overfeeding on "rich" cow's milk as in underfeeding on watery milk and cereal dilutions, and in poisoning the little body with inorganic minerals.

As regards germ infection and the necessity for pasteurizing the milk, the menace to health and life is greater through
malnutrition than through germs and bacteria. Germs we cannot escape, not even if we were surrounded on all sides by walls of air-purifying and antiseptic materials.*

*Since the foregoing was written we have learned that low vitality and morbid soil will develop perfectly normal microzyma into so called disease germs.

One of the foremost French bacteriologists claims that in the mouths of infants shortly after birth he has found almost every disease bacillus known to medical science.

William Osler, M.D., to whom the English language is indebted for the verb "to oslerize," says in *The Principals and Practice of Medicine* on page 151, in the chapter on Diphtheria:

"The presence of the Klebs-Loeffler bacillus is regarded by bacteriologists as the sole criterion of true diphtheria, and as this organism may be associated with all grades of throat affections, from a simple catarrh to a sloughing, gangrenous process, it is evident that in many instances there will be a striking discrepancy between the clinical and the bacteriological diagnosis."

In the first part of this sentence he states that bacteriologists regard as the sole criterion for the diagnosis of diphtheria the Klebs-Loeffler, or diphtheria, bacillus; in the last part of the sentence he admits that this bacillus is found in even slight catarrhal conditions, and he might add that it is found just as frequently in the mouth and throat of healthy infants and adults. This is a good example of "orthodox" scientific reasoning.

If germs and bacilli of themselves could destroy health and life, the human race would in a short time become extinct. Disease germs are omnipresent. They permeate the tissues of our bodies and in the intestinal tract swarm by millions. Whether they prevail depends upon natural resistance, or reserve force, and upon the disease soils in the system. The air we breathe is saturated with all sorts of disease germs or their microzyma.

Since baby cannot escape germ invasion, the real problem is how to increase the resistance of the little organism and how to purify it of morbid matter so that disease germs will not find anything to feed on.

Resistance depends largely upon proper nutrition. Diluted, watery milk, contaminated by inorganic minerals, is not a good nutrient; its nutritive value is still more reduced by pasteurizing or boiling. Heating milk or any other proteid food above 1500 F. coagulates the albumen, disorganizes organic compounds, precipitates salts and dissipates the life elements. This reduces the nourishing value and digestibility of the milk.

Nature does not provide the young animal with boiled or
pasteurized milk, and we should not lower food values by such methods.*

* It is now admitted that pasteurization and boiling kills "newly discovered vitamins" which are the "life elements" constantly referred to in my earlier writings.

I do not wish to intimate, however, that scrupulous care and cleanliness should not be exercised in the selection and handling of the milk.

Wherever possible, secure the milk of a single healthy cow that grazes on green pastures or is fed on normal clean food mixtures. Milk from cows kept in stables and fed on brewery and distillery slops and other refuse should not be used.

Every vessel and utensil with which the milk comes in contact must be carefully scoured, submerged in boiling water, drained and kept in a light, airy place.

The nursing bottle, after each feeding, must be taken apart and carefully scrubbed, inside and out, in hot water with an addition of a little soda. It should then be left in pure, cold water, until the next feeding time.

2. When to Feed. Physicians quite generally recommend feedings at stated hours, in fixed quantities.

This is altogether wrong, it establishes at once the stuffing habit, does not permit the development of natural desire and its regulation. The infant very soon becomes accustomed to eating at certain times, whether it really needs the food or not.

Food should not be given until there is an actual demand for it, which will express itself in real hunger. By careful observation and experiment the mother will soon learn to distinguish the ordinary crying of the baby and the desire for food expressed by it. If this practice of feeding only when there is a natural desire for food is strictly followed, the infant will soon establish its own regular feeding times, usually at intervals of about three or four hours in the daytime. The stomach digestion of a feeding of milk will require about three hours, therefore a minimum of that much time should be allowed between feedings after the first few weeks.

If the mother can nurse her baby, it should be put to the breast upon awakening from its first sleep, either before or after bathing and dressing.

The first secretion of the breasts (colostrum) is not really a food, but performs an important function in cleansing the intestinal tract and preparing the digestive system to properly digest and assimilate the milk when it comes, usually about the third day.

3. How to Feed. If artificial feeding must be resorted to, no food at all should be given, except a few teaspoonfuls of water, during the first twenty-four hours after birth. During
the next few days, cow's milk should be given, well diluted—about one-half milk and one-half filtered or boiled water. From week to week the amount of water should be reduced until at the end of the second month the baby takes cow's milk undiluted.

4. Night Feeding. In the nighttime feeding should not be encouraged. During the first four months it is advisable to feed not more than once during the night. After that the child should be weaned from the habit entirely. This will be facilitated by giving a drink of water instead of milk.

5. Amount of Food. Discretion should be observed in determining the amount of food. Do not induce the baby to take as much as possible, rather as little as possible. Its welfare does not depend upon the amount of food consumed, but upon the amount which it can easily digest and assimilate.

When more food is given than the digestive organs can take care of, the entire mass may ferment and sour.

6. Grain Extracts. If undiluted milk proves too rich, grain water may be added. In order to prepare this, take clean grain as it comes from the field, crush it in a hand grain mill or a new coffee mill, take three tablespoonfuls of the crushed grain to one pint of cold water, and boil on the stove for one hour; or in the fireless cooker for two or three hours, in which ease use a little more water at the start. While the gruel is boiling over the fire, add enough water to allow for evaporation and absorption. When thoroughly cooked, strain the gruel through a fine cloth or sieve. Add one tablespoonful, or more if necessary, to each milk feeding.

When baby is constipated, add to the milk, grain extract made from oats, and frequently cool the bowels with cold water. This will cure the most stubborn constipation. If the bowels are too loose, add to the milk, extract made from barley or wheat.

The small particles of hulls in the grain extracts improve digestion and evacuation, in a mechanical manner. They permeate the curds and keep them from coagulating too solidly, thereby facilitating the penetration of digestive juices; they also exert a mild stimulation on the walls of the intestines, thereby increasing the peristalsis of the bowels and evacuation of feces.

7. Baby's Natural Medicines. Fruit juices and scraped raw ripe pear or apple and the pulp of cooked fruits such as prunes or figs without addition of sugar or sweetening of any kind, are baby's finest medicines. They increase the supply of organic salts for blood, nerve and bone building and for purposes of elimination. They are nature's own cholangogues, laxatives, tonics and antiseptics. They keep the little body sweet and wholesome. All babies under our care receive fruit juices beginning with the second week.
During the first two months, give one teaspoonful of orange juice, grape fruit juice or prune juice, one hour before or after each nursing. After the second month, gradually increase the amounts of fruit juices and begin to add raw pear or apple scraped with a spoon or dull knife, or the mashed pulp of fully ripened peach or grapes.

8. Weaning the Baby. Nursing infants should be weaned from the breast after the eighth or ninth month. From the sixth or seventh month, both nursing and bottle-fed babies should begin to take some solid food. The best of these to begin with are whole-grain cereals, gruels, raw and cooked fruits and tender vegetables in small amounts. Mealy baked potato is one of the best foods, better than the cereals.

9. Feeding After First Year. After the lapse of the first year, the solid foods are gradually increased and the milk reduced in quantity. Eggs should not be given before the eighteenth month, then soft-boiled or poached. During the second and third year half an egg twice or three times a week is sufficient; after that an egg at a time may be given once or twice a week.

Meat and all other foods prepared from the dead animal carcass are bad enough for adults, but it is inexcusable to give them to tender infants and children.

Dog fanciers, when they sell a valuable canine, usually advise the buyer not to give the animal any meat before the second year, lest it become a victim of distemper; and dogs are naturally meat eaters.

Well informed physicians now generally advise not to give meat to children before the fifth or sixth year. They have learned this much from the nature cure people.

Foods undoubtedly have a powerful influence, not only on the physical body, but also on the mentality and the emotions. These problems will be interesting subjects of investigation for the food chemist and psychologist of the future. In general, we may say that flesh foods are stimulating and feed the passional nature, while fruits and tender vegetables refine and stimulate brain and nerve matter as well as the intellectual, emotional and spiritual activities. Cereals, nuts and pulses build and repair the physical body and supply the body with heat and muscular energy.

The majority of animals adhere strictly to one kind of food, and therefore faithfully exhibit in their mental and emotional characteristics the effects of different food materials. Ferociousness we find personified in the carnivorous bulldog, lion, tiger and panther (that is why soldiers are fed on meat three times a day); gluttony and omnivorous voraciousness in the hog, chicken and hyena; cold-blooded cunning in the fox, and cruelty in the cat. The intelligence of the carnivorous animals displays itself mainly in the cruel cunning with which they stalk their living prey. It resembles in quality the low
Personifications of great physical strength, intelligence, endurance, patience, gentleness, fidelity, affection and self-control, we find among the vegetarian animals. The beaver, the arboreal ape and the elephant are especially noted for their intelligence; deer, antelope and sheep for gentleness; the horse for its almost human intelligence, affection and fidelity. Oxen, elephants and camels for their great strength and endurance.

**Meat is detrimental to the child in every way**, physically, mentally and morally. The poisonous acids and alkaloids which it contains clog the capillary circulation, causing anemia, coldness of the extremities and defective elimination through the skin. This results in congestion in the interior organs, high blood pressure in brain and heart, headaches, nervousness, irritability, tendency to fevers, inflammations and catarrhal conditions.

With the meat, the child often absorbs the eggs of worms, tubercular bacilli, and other parasites and disease germs. Certain forms of epilepsy, St. Vitus' dance and hysterical conditions are due to uric acid poisoning and to other pathogenic materials and ptomains contained in flesh foods. Such patients, in times of crises, frequently emit pronounced odors of raw meat or uric acid. Strictly vegetarian diet, combined with other eliminative natural methods of treatment, cures the majority of these cases.

Most of these poisonous acids, alkaloids and ptomains contained in the flesh of dead animals are powerful stimulants. I have frequently noticed that people who have abstained from meat for a long time, when they first partake of it again experience sensations and exhibit symptoms resembling those of alcoholic intoxication.

We have learned that these stimulating extractives of flesh foods chemically closely resemble caffeine, thein and nicotine. The use of one or more of these stimulants invariably creates a craving for the others. This explains why a heavy meat eater is usually a confirmed coffee drinker or inveterate smoker, and vice versa; and why we find it almost impossible to wean people from one of these stimulants as long as they persist in taking the others.

The legumes or pulses—peas, beans and lentils—are close seconds to meat in acid-producing qualities. Eggs contain considerable ready-made uric acid and a great deal of sulfur and phosphorus. These may become dangerous to the organism. For these reasons, meats, legumes and eggs are always danger foods for the child.

Children brought up on such foods will show the effects in nervousness, irritability, lack of self-control, craving for cigarettes and alcoholic stimulants. The most serious aspect of this question lies in the stimulative influence of meat poisons.
on the sex centers. It is a well known fact, verified by close
observation, that flesh foods stimulate the sexual passions to a
marked degree. This tendency is greatly increased by the use
of coffee, tea and alcoholic stimulants in the form of wines,
liquors or medicines. If the sensitive nervous organism of a
child is overwrought by these powerful irritants, there can be
but one result; precocious sexual awakening.

From the third year the child may gradually adopt with
slight appropriate modifications, a diet as outlined under Sec.
I, No. 10, and Sec. X, No.7.

SECTION XL
Exercises in Infancy

1. Exercises in Infancy. Proper exercise is important from
the very beginning of life. A baby will follow its natural
instincts for exercise if allowed to do so, by working its arms
and legs and writhing its little body in all directions, if not
unduly hampered by tight clothing and bandages. A few nude
air baths every day will afford excellent opportunity for
baby's gymnastic stunts.

After he is a few months old he may be placed on his
stomach, when he will exert himself vigorously by trying to
raise his head, to turn around, or to raise himself with his
arms. He will soon learn to roll over and to creep lie nay now
be pulled up gently by his arms and lowered again a number
of times in successiion.

When three or four months old he may be lifted by one arm
or by both arms; by the right arm and left leg, or by the left
arm and right leg. When the baby is six or eight months old,
he should be strong enough to rise from his back to a sitting
position. This may be encouraged by holding down the feet. I
have known a number of nature cure babies who at six
months of age clung tightly to a stick while being lifted a few
feet from the bed. Another good exercise greatly enjoyed
by the youngsters is to roll them back and forth on a bed.

The average healthy child will secure ample exercise while
learning to walk and run and while playing with simple toys
or with other children; but this may be supplemented to good
advantage by special exercises devised by the father and
mother. Nothing is better for the health and happiness of both
parents and children than to join in merry romp and play.

Between two and five years of age the child may be taught
more difficult stunts, performed either by himself or with the
assistance of the father or mother; but swinging the child
high overhead, throwing him up and catching and other
dangerous tricks should be avoided. They are risky and
have very little effect in developing the body of the child. The
best exercise at this age consists in outdoor play and games.
From the sixth year, the question of exercise becomes a more important one, especially since the children are confined for many hours in school rooms. If exercise at this time of life, through play and games and special gymnastics, is neglected, it may affect health, strength and efficiency of the child for life.

Those of good physique and ample strength may gradually take up and practice the exercises for adults outlined in sections XXI, XXII, XXIII, XXIV.

2. High Chair. A baby should not be put in a high chair until he is quite well able to hold the spine and head erect, and should never be left in a chair for any length of time. If a baby is forced to maintain a rigid, sitting position for a considerable time, before the bones and muscles are sufficiently developed, this may produce deformity of the spine. Maids and nurses, if not properly supervised, sometimes fasten a baby in a high chair and leave him there to take care of himself for long periods.

3. Toys. Since most babies have a habit of putting everything into their mouths, toys must be selected that can do no harm. They should have no paint, no sharp points or corners which might hurt the eyes or mouth, and must be of material which can be easily and thoroughly cleansed. Hairy and woolly playthings are unsafe, being unclean and germ carriers. Objects small enough to be swallowed must never be put within baby's reach. The simpler the playthings the better; a few clothespins, empty spools, or other simple objects are better than expensive toys.

SECTION XLI

Baby's Ailments

1. Hernia As a result of a weakly or sickly condition of the mother during pregnancy and of faulty prenatal management, many children are born ruptured. So far I have not known a single nature cure baby that was born ruptured. Such defects are due to weakness of the tissues. This results from mineral starvation. The tissue walls contain too much mortar (protein) and not enough building stone (mineral salts). Prevention of hernia, therefore, lies mainly in proper diet of the pregnant mother, but all the rest of the prenatal regimen described in these pages is of great importance in preventing this and other ailments and deformities.

There are three principal points at which rupture or hernia may take place in infancy—at the navel, in the groin, and at the line between the navel and the lower end of the sternum. Other kinds of ruptures are extremely rare.
2. **Umbilical Hernia** This is a protrusion of the intestine at the navel. It is the most common rupture in infancy. Pulling on the cord during childbirth, urging at stool or violent crying may result in rupture. The umbilical ring first expands and this forms a pouch into which one of the folds of the small intestine protrudes.

Treatment: Of primary importance is the diet as outlined herein. The baby must have plenty of fruit juices in order to reinforce the mineral salts in the milk. Cold bathing is very beneficial. The rupture itself should be cleansed several times a day with warm water. This must be followed by a wash with cold water mixed with lemon juice. Gentle, passive exercise, such as raising, lowering and twisting the limbs from side to side, also raising and lowering the body while supporting the shoulders and head, is of especial value.

The rupture must be reduced and kept from protruding by placing over it a large button or other article of similar shape, wrapped in gauze and held in place by broad strips of adhesive plaster. The adhesive tape is fastened over the button crosswise and must be applied in such a manner as to draw the skin from all sides over the rupture. Instead of the button, a compress made of gauze may be laid over the rupture and held in place by one broad adhesive strip. The covering of the rupture must be removed and renewed every day in order to allow cleansing, as before described.

When the child is old enough to exercise by himself, he should be taught special movements of the body and the limbs which develop the muscles of the abdominal region.

3. **Ventral Hernia.** This occurs along the middle line of the body between the navel and the breastbone, sometimes below the navel. The rupture may not be larger than the size of a pea or small marble, and may disappear on pressure. The treatment is the same as that of umbilical hernia.

4. **Inguinal and Scrotal Hernia** occur in infancy or in adult life; sometimes the inguinal canal does not close after the descent of the testes from the abdominal cavity into the scrotum, and the intestine descends through the open canal, thus producing the rupture. These forms of hernia become aggravated by coughing. They can be reduced immediately with gentle manipulation while the patient is lying on his back. This kind of rupture may be distinguished from hydrocele by the fact that in reducing it goes back easily with a gurgling sound. Hydrocele is not affected by coughing. A hernia is opaque to transmitted light; hydrocele, transparent.

These ruptures should be protected with a well-fitting truss. This has to be removed daily for cleansing of the parts. Appropriate exercises, passive and active, together with cooling sitz baths and washes with cold water and lemon juice are the best remedies for these, as well as of other forms of rupture.
5. **Congenital Hernia** occurs in the form of inguinal hernia and has to be treated in the same way. Ruptures of any kind must be reduced and properly supported. Constipation and consequent urging at stool may cause or aggravate any form of hernia and must, therefore, be overcome by the right treatment described under section XXVI, No.1.

6. **Colic.** This is usually caused by indigestion due to overfeeding, improper feeding, or too frequent feeding. The intestines are distended with gas, giving rise to a severe pain. The baby cries sharply, alternately drawing its legs up to the body and kicking them away. One of the quickest means of relief is a small enema of warm water and gentle circular massage of the abdomen from right to left. Food should be withheld until the symptoms have disappeared. The giving of milk or other food may quiet the attack temporarily, but the pain is apt to return with greater intensity. Warm water may be given if the baby will swallow it.

A baby managed in the natural way prenatally and postnatally is not likely to suffer from this ailment. Constipated babies are more prone to it than others.

Colic may also be caused by sudden chilling. In that case a warm bath for five or ten minutes, followed by gentle body massage will bring about a warm reaction.

7. **Convulsions.** These cause a great deal of anxiety to the fond mother. They are always reflex symptoms of some slight or serious internal disturbance due to wrong management. They commonly result from some form of auto-intoxication caused by digestive disturbances, and the resulting systemic or drug poisoning. An inactive condition of the skin, bowels or kidneys will favor auto-intoxication and convulsions. If proper care is taken to keep the system pure, and the organs of elimination in active condition, convulsions will not occur.

The best treatment during an attack is a quick, cold rub all over the body; application of a whole body or trunk pack; gentle soothing magnetic massage, and neurotherapy treatment. These treatments draw the blood into the surface and relieve congestion in the brain and nervous system.

8. **Ailments of Teething.** Many ailments of children are laid to teething, but this is a mistake. Well managed, healthy babies go through the teething period without any trouble whatsoever. This is practically always true of nature cure babies. When, however, the little body is heavily encumbered with hereditary and acquired morbid materials, food poisons and disease taints, the process of teething will not run its natural course and may precipitate any form of disease crisis.

When teething is difficult, it is frequently associated with digestive disturbances. Diarrhea may alternate with constipation and vomiting is of common occurrence. The baby may be restless and fretful. He tries continually to bite on something in order to facilitate the projection of the teeth
through the hardened gums.

No teething lotions or soothing medicines of any kind should be given for the relief of pain in teething. They all contain poisonous sedatives which benumb and paralyze the nerves and have serious after effects upon the system. They usually contain opium in some form, or other narcotic drugs.

The only way to prevent these and other infantile ailments is to keep the little body as nearly normal as possible through the natural treatment described in these pages. If this is closely adhered to, it will prevent, in many cases, the development of even measles and other common eliminative infantile ailments.

During this critical period in the baby's life the diet must be extra light; starchy food should be reduced to a minimum and replaced by raw and cooked fruits and vegetables juices. Cooling sitz baths will help to keep the bowels active and to abate internal fever.

9. Acute Catarrhal Disease. Acute catarrhal diseases of infancy such as croup, cold in the head, acute bronchitis and whooping cough, are different forms of acute elimination through which Nature tries to purify the little body from hereditary and acquired accumulations of morbid matter, systemic poisons and disease taints.

In accordance with this conception of acute diseases, as purifying, healing efforts of Nature, we would not do anything to check or suppress elimination but cooperate with Nature in her purifying, healing efforts. How we do this has been fully explained in other parts of this volume. (Section VIII)

The natural treatment is very much the same in all acute inflammatory ailments. Feeding must be reduced to a minimum. If the baby does not insist upon eating, nothing should be given except water with acid or sub-acid fruit juices, such as lime, lemon, grape fruit and orange. If the temperature does not run high, say not above 100 or 102 deg, frequent ablutions with cold water at intervals of from one to two hours will be sufficient to promote heat radiation and elimination of morbid matter through the skin and other organs of elimination. If the temperature runs' higher, say between 102 and 105 deg, wet packs must be applied, and renewed when they become hot or dry.

The wet packs are of especial value in all kinds of cough; whether it be the ordinary cough, croupy cough or whooping cough. A whole body or trunk pack, with or without a throat pack, will give almost instant relief. In many instances where baby is making the night hideous for the anxious mother, with it's coughing, a well-applied whole body pack, or a combination trunk and throat pack, will relieve the coughing almost instantly, and induce restful sleep.
In serious cases it is always advisable to call in a natural therapist or some other drugless physician, if one can be reached.

The mother should not forget that all acute diseases, after they have once developed, must run their natural course. She must, therefore, not become impatient and lose faith in the natural treatment if it takes a week or more to cure a common cold in the head or an attack of bronchitis, or if it takes from two to eight weeks to cure a case of whooping cough. Serenity, patience and cheerfulness are the primary requisites of the nature cure physician.

PART IV

BABY BOOK

Natural Therapeutics has undoubtedly solved the problem of treating human ailments. All other schools and systems will in time have to adopt the natural way. It is the hub of the healing art; all therapeutic methods radiate from it like spokes from a wheel.

Natural Therapeutics, however, has something better to give than treatment of disease, and that is prevention of disease. If children were brought into this world in the manner ordained by Nature and reared in harmony with the teachings of natural philosophy, disease would soon be a thing of the past. Human beings would then enjoy good health and be as beautiful and perfect in their kind as are animals, which live in the freedom of Nature, guided by instinct and therefore in harmony with the laws of their being.

We must begin, then, with prevention, for prevention is always easier and cheaper, than cure. But where must we begin to study the prevention of disease? Some will say, "At birth, because that is the beginning of life." Not so: that would be too late. The mould is made and the foundation laid for health or disease, for happiness or suffering, for efficiency or deficiency, before the human being in process of creation sees the light of day.

"Then," it may be said, "we must begin with prenatal influence, for the physical, mental, emotional and moral habits of the mother influence powerfully the development of the new life she is carrying." True—but we must start earlier than that. The making of the human being begins with mating and conception. All subsequent development depends upon the right start.

SECTION XXXII

Heredity

1. Importance of Correct Mating. Of primary importance in the sacred rite of procreation, as already intimated, is mating. This should take place only between descendants of the same subrace, or of closely related subraces such as the Indo-Caucasian and Celtic.

If the racial descent of the marriage partners is so far removed that it has produced pronounced differences in racial
characteristic—as in the case of the swarthy Mexican and white skinned Englishwoman, or the dark eyed Magyar and blue-eyed Scandinavian—then procreation becomes miscegenation and degenerates into mongrelization of the offspring. Everywhere in the animal and human kingdoms Nature has set the mark of disapproval on the mongrel. The offspring of miscegenation is doomed to deterioration and extinction unless assimilation of the elements of a lower race by a higher takes place sparingly and gradually.

The law of racial purity may be summed up as follows: When a member of a higher race cohabits with a descendant of a lower race, the offspring of the union loses more or less the characteristics of the higher race and reverts in physical, mental and moral traits to the level of the lower race.

The constructive results of racial purity are evident in Hindus of the higher castes; in that portion of the Jewish race which in mating has faithfully adhered to the Law of Moses, and in the blond and blue-eyed remnants of the Indo-Caucasian and Celtic races in Northern Europe and North America. The destructive results of miscegenation are plainly evident in the mongrelized population of Mexico and everywhere in the half-breed and many kinds of mixed breeds. These usually fall below the physical, mental and moral standards of the parent stock, and almost invariably revert to the customs and habits of the inferior race.

2. Use Heredity. Use heredity deals with the transmission to offspring of acquired physical, mental and moral characteristics of the parents. According to this law as it has been formulated, the chances of the offspring for long life, health, mental efficiency and moral stamina, other conditions being favorable, are better in direct ratio to the advancing age of the parents at the time of conception. While this is contrary to popular opinion, which assumes that younger parents produce more perfect offspring than older ones, the fact of use heredity is proved, both in the animal and human kingdom, by common observation and statistical evidence.

The working of the law is based on the fact that the procreative elements of the parents, or rather the microzyma of those elements, cannot contain the impress of physical, mental and psychical characteristics which at the time of procreation were not developed in the threefold organisms of father and mother.

The age of the father at conception is called the "birth age" of the offspring and determines its birth rank. While the father and previous male ancestors, for reasons hereafter explained, seem to exert greater control over the mental and physical characteristics, the mother furnishes the nutrient soil for physical growth. This does not mean that she exerts no control over the mental and psychical characteristics of the offspring; in addition to her influence through use heredity she has added opportunities through prenatal influence and postnatal training.
According to this law, then, the chances of the offspring for excellent physical, mental and moral development become better as the age of the father at the time of procreation advances beyond thirty five; while the physical condition of the mother for reproductive function is best below thirty five years.

But we must not overlook the fact that too great a discrepancy of age between the man and woman may become the cause of physical and mental incompatibility, of aversion and great unhappiness, especially on the part of the younger woman.

Extensive statistical evidence seems to prove that the birth age of the mother has been of less importance than that of the father. As will be shown in Natural Eugenics, the majority of famous men in all lines or human endeavor had old male ancestors, while the mothers and previous female ancestors were of much younger age at the time of conception.

This may be accounted for by the following reasons:

The man is usually considerably older than the woman at the time of marriage. Men, as a rule, devote much more time and effort to acquiring a scientific, professional or business education than do women. This has been true in the past more than it will be in the future. Thrown early into the competitive struggle of life men generally have had to make greater mental and physical effort than have women.

These points are of considerable importance because it has been proved that it is not inherited brain mass and mental capacity, but strenuous and persistent effort that intensifies use heredity. The earlier this begins and the longer it continues before procreation takes place, the better the chances of the offspring for physical, mental and moral capacity.

The reproductivity of the mother has usually ceased at thirty-five. Though she be capable of childbearing a few years longer, usually conception has been avoided after that age. Men under favorable conditions remain reproductive to advanced age. Some of the world's greatest men descended from fathers over sixty years old.

That intellectual and creative capacity has followed the male line of descent rather than the female line, is indicated by the fact that the high intellectual capacity of many eminent men has skipped their daughters to reappear in male descendants. This may be partly accounted for by the fact that the daughters in their limited spheres of activity have not had the opportunity to unfold inherent intellectual capacity to any conspicuous degree.

There has been a tendency in some quarters to criticize the general entrance of women into professional and commercial life and to dilate upon the adverse influence this will have
upon womanly characteristics and family life.

In the light of the knowledge we possess upon the subject of use heredity, it is safe to say that any such problematical drawbacks will be far outweighed by the general postponement of the marriage age. This will insure not only better physical fitness but also higher intellectual development and greater moral stamina on both sides of parentage.

The tremendous benefits which this increased hereditary endowment will confer upon future generations cannot be overestimated. Greater intellectual and economic equality between the sexes will emancipate woman from degrading sexual subservience. Under the old order, sex appeal was too often her only stock in trade by which to attract and hold the male and thus to secure a living. Economic independence will insure greater consideration and higher esteem for the woman on the part of the man. It will go a long ways toward solving the problem of birth control in a natural way, by leaving it more largely to the judgment of the mother.

We find the law of use heredity according to birth age verified in the intelligence and moral development or obliquity of races, nations and tribes all over the earth—The lower the average birth age of a race or nation, the lower, other things being equal, the intellectual and moral development The greatest development and efficiency is found among those nations where marriage is delayed to a later age through custom, economic necessity, professional or military training.

The following quotation from "Control of Heredity", by Casper Lavater Redfield, is of interest in this connection:

"In general it may be said that wherever there are no restraints upon the sexual propensities, as with the Digger Indians, the Fuegians, the Andamanese, the Wauraus of the Guianas, the Bushmen and the tribes along the Gabbon river, there we find reproduction taking place at the earliest possible age, and the lowest grade of intelligence. Where we find some special circumstances or customs that delay the age at which reproduction takes place, as with the Patagonians, the North American Indian and the Polynesians, there we find considerably higher grade of intelligence.

"Where we find the custom of marrying late in life, as was customary with the Greeks and the Romans, there we find a very high grade of intelligence. And where we find a fortuitous succession of very late births, there we find the very great men of the world's history.

"In other words, the longer the time in which the individuals have in which to use, develop and strengthen their brains before reproduction begins, the greater and more powerful are the brains of their descendants."

In Volume IV of this Series I shall quote elaborate and
highly interesting statistics from Redfield, which reveal the effects of the various birth ages on physical, mental and moral characteristics. I shall confine myself, for the present, to the statement that, with few exceptions, the great artists, scientists, philosophers, statesmen and philanthropists were born from fathers whose ages ranged from forty to sixty-five years at the time of the procreation of their famous offspring.

The existence of these laws and principles as facts in nature is very evident in the training of racehorses and of other animals along certain lines of proficiency.

3. Pernicious Heredity. The effects of deteriorating and destructive heredity prenatal and congenital influences have been traced and commented upon in so many different ways that I do not believe it necessary to enter deeply into this phase of the subject. Various authors have filled entire volumes with the unsavory family histories of the descendants of the Jutes, Ishmaels and other drunkards, prostitutes, degenerates and criminals, which prove positively the transmission of morbid and pernicious traits through successive generations. It has been proved statistically beyond the shadow of a doubt that youthful delinquency, pauperism and criminality are the aftermath of immature marriages.

The laws of use heredity and prenatal influence, like all other natural laws and principles, manifest along opposite lines of expression. It remains for us to determine whether we shall align ourselves with their destructive or constructive activities. The effects upon ourselves and our offspring will show accordingly.

If I succeed in arousing the consciousness of prospective fathers and mothers to the glorious privileges and enormous responsibilities which these laws of nature confer upon them, then my labor will not have been in vain and I shall feel deeply gratified.

SECTION XXXIII

1. The Creative Alchemy of Love and Affection

Procreation—as is the case with everything else pertaining to the constituents and functions of the human entity—takes place on three planes of being, the material (physical and spiritual), the mental and the psychical planes. Which of these elements shall predominate in the offspring depends upon the mixture and adjustment of qualities in the triune makeup of the mating couple. In order to fulfill the law and to draw the divine blessing upon themselves and the fruit of their union the partners in the procreative function must be united by the bonds of love, or at least by the ties of true affection.
The source of creative genius is love and wisdom, and the essence of intelligence and power is sincerity and goodness. Without these, intelligence degenerates into selfish cunning, power into self-destructive brute force. The spring cannot rise higher than its source; its water cannot be pure and wholesome when contaminated by impure admixtures from filthy surroundings.

It is not generally known that use heredity pertains to intellectual and psychical qualities, as well as to the physical material. Animalism breeds nothing but selfish animalism. The vampire who craves and absorbs the love of its victims and robs them of vital energy, without being capable of feeling or bestowing affection, is the child of a discordant union—of brute animalism on the part of the man, of secret aversion and hatred, usually, on the part of the woman. These bestial and degrading tendencies on the one side, and unrequited love craving on the other, breed sex perversion, and propagate the harpies who delight in the seductive power of superficial beauty, while gloating over the weakness and ruin of their victims.

True love and affection, paired with intelligence and goodness; liberate the creative elements necessary to the production of perfect offspring.

The finer qualities of mind and soul open the fountains of life on the higher planes, liberate and harmonize the male and female procreative fluids, and charge them with the purest and most potent intellectual, spiritual and psychical elements.

The divine fire of creative genius burns only in the love aura of truly mated couples. It is true that these are rare under our artificial, unrighteous social institutions, and that accounts for the rarity of complete manhood and womanhood.

Perfect offspring, endowed with beauty and power of body, mind and soul, destined to shed through life a radiance of health, happiness and helpfulness—to love and be loved—issues only from the union of love and affection with intelligence and goodness.

"Love lieth at the foundation" (of all that is). "Love is passion, enthusiasm, affection, heat, fire, soul—God."

To the extent that love enters into the holy rite, to that extent its attributes will be absorbed in the threefold organism of the woman and become active in the child building in her womb. While she loves her man more than ever, her most passionate affection is centered in the new being in process of development. On it she bestows the purest and best in her food and drink, in her thoughts, emotions and secret desires. Fear, worry, anxiety, jealousy and hatred are strangers to her soul; these are the emanations of the lower spheres—she lives in heaven.

Somebody endowed with deep insight into these matters has
"Whatever male and female shall truly will for, hopefully pray for and earnestly yearn for, when love pure and holy is the nuptive ascendant, in form, passional, affectional, divine and volitional, that prayer shall be granted, and the boon be given—but the prayer must precede."

What are the direct effects of the marital rite upon the participants? If the sex attraction operates on the physical material plane only, if lust instead of love presides at the matrimonial feast, then temporary gratification of erotic craving will be followed inevitably by monotony, satiety, gradual revulsion and aversion, culminating in a morbid craving for change and variety. The partners in carnal self-indulgence are intuitively aware of these tendencies to marital unfaithfulness, and, therefore, easily dominated by distrust and jealousy.

The procreative function is attended by complete satisfaction, buoyancy of body and mind and lasting happiness only when sex attraction operates on the higher and highest planes of being, as well as on the lower; when desire and impulse are operative on both sides. Thus only will the generative function fulfill its sacred purpose and confer the highest possible benefits upon parents and offspring.

The woman, being the more highly sensitized, must be responsive to the call of holy passion. To force unwilling compliance will ruin the woman, kill her love and curse her offspring. Balzac says: "He who begins with his wife by a rape is a lost man." It is impossible for a wife to love unless she is won, not forced to compliance.

2. Sexual Intercourse During Pregnancy. Sexual intercourse should be considered the most sacred function of the human entity. From the highest and best viewpoint it should be exercised only for the propagation of offspring. However, considering the present stage of ethical and moral development, temperate indulgence may not be wholly condemned. Excessive intercourse is always weakening and harmful to both participants. We must remember that the sex fluid is the carrier of the life force. It is that which constitutes strength, resistance to disease, initiative and genius. During abstinence from intercourse the sex fluids with their creative energy are absorbed through the inguinal glands into the organism and increase physical, mental, moral and spiritual capacity and energy.

Set rules for frequency of intercourse cannot be given. This must depend entirely upon individual conditions. One safe rule is that after indulgence there should be no feeling of satiety, weakness and exhaustion. The more frequent the indulgence the stronger will grow the power of habit and of passion and the greater will become the abnormal craving. It is the same with all other appetite and passions. The more frequently they are indulged, the stronger they grow, until
they attain complete control and develop into destructive habit

A free and confidential understanding in regard to these matters between those who contemplate matrimony would go far to prevent marital misery. A great deal of unhappiness arises from the fact that mates in the matrimonial union often labor under misapprehensions concerning the attitude of each toward the sex relation, and are prevented by excessive sensitiveness and delicacy from frankly discussing it. (For further discussion of this subject, see page 390, Volume I.)

There is no problem of married life that needs more thorough mutual consideration and understanding than this one. Lack of it accounts for a great deal of "incompatibility," loss of love, revulsion, hatred, and the final tragedy in the divorce court.

Among animals, no female allows intercourse after conception. In this respect as in many others, man has sunk below the natural standards of the animals. No greater crime can be committed against the woman and the unborn life.

It is a sad commentary on our system of education, scholastic as well as religious, that our young people are not instructed before and after marriage in these all important laws of Nature. To do this should be the province of the priest who unites them in marriage, or of the family physician, if the parents have failed in their duty.

It is well known (notwithstanding the denials of medical skeptics) that the unborn infant may be "marked" by transitory impressions, especially by strong emotions; that even insignificant parental characteristics are reproduced in the offspring. Is it any wonder, then, that the most powerful of human emotions should leave its impress on the growing brain and sex centers of the fetus, causing abnormal and precocious sex consciousness?

All too often is sex perversion born and bred in bone and flesh, before the child sees the light of day. The mother cannot be blamed for this "slaughter of the innocents"; she has not been instructed on the subject. Though she intuitively senses the horror of it, she submits, in order to maintain her hold upon the man—and many a life is thus cursed before it is born. The fault lies primarily with those of the medical profession who teach our young men that the free indulgence of sexual passion is not only legitimate, but a necessity to manly vigor.

This dictum of pseudo-science is almost universally concurred in by spiritual guardians. No greater lie was ever promulgated from the blackest abyss of Hades. If our young men were taught that greater happiness is to be attained by the exchange of tender affection than by the indulgence of the coarser animal appetites, that the creative forces thus preserved develop and strengthen their own finest capacities
of body, mind or soul, they would wisely and chivalrously protect mother and child, at the same time conserving their own physical and moral integrity.

In no other way is it possible to call forth the deepest gratitude and unfailing esteem of a true woman. Many a man whom we have thus advised has become a lifelong friend in consequence.

3. Limitation of Offspring. I believe that the unlimited production of offspring, encouraged in some quarters for swelling the ranks of religious bodies or for increasing tax paying and cannon-fodder material, is a misfortune, both to the family and to society. Limitation of offspring, in accordance with the means and circumstances of the parents, is not only justified but should be encouraged. In any case, the production of offspring entails great responsibility upon the parents and if they cannot properly comply with the needs and rights of their children, they fail in their responsibility and duty.

Any method, however, which interrupts intercourse or prevents conception in an artificial way, is absolutely to be condemned, because this has very harmful and positively destructive effects upon the physical, nervous and mental organism of those who thus try to cheat nature by the suppression of a natural process. In our professional work we frequently meet the victims of such pernicious practices. The ordinary contrivances for prevention make of intercourse something akin to masturbation. This is also true of intercourse without orgasm which is strongly advocated under various guises. The use of poisonous antiseptics and germ killers in warm water douches is not essential for prevention, and is highly injurious. These chemicals have a tendency to poison the sexual organs and to produce in time atrophy, many kinds of female disorders, and tumors. Undoubtedly the greater number of so called female troubles and malignant tumors in later life are caused by curetments, antiseptic douches and the use of poisonous drugs, for producing abortion. The only legitimate methods of birth control are abstinence or common cleanliness.

There is nothing more conducive to the physical, mental and spiritual health and development of a woman than childbearing and child rearing in harmony with Nature's laws, as outlined in these volumes. Under favorable conditions it is not a thing to be dreaded, but to be looked upon as the greatest of blessings and opportunities in the life of a woman. Natural philosophy and practice takes these problems of progeneration, childbearing and childrearing out of the domain of uncertainty and haphazard management with its dire consequences, and makes eugenics the most exact of all sciences and the sublimest and most enjoyable of all the arts.

4. Determination of Sex. Numerous theories have been advanced concerning this interesting subject. Many attempts have been made to wrest from Nature the secret of sex
determination and numerous more or less ingenious methods have been recommended for sex control.

I know of one method only which seems to have a rational basis and which has proved of practical value. Observations seem to prove that the right ovary liberates male ova only, while the left ovary discharges female ova. The two ovaries discharge ova only at alternate menstruations.

With this data at hand, it is possible to determine the sex of a child after one birth has taken place. Suppose the first child was a boy. By consulting our pregnancy table (page 377) we can determine when the last menstrual discharge took place. This menstruation liberated a male ovum; the next menstruation would liberate a female ovum, the next a male, etc.

Thus, using the last menstruation period before the last conception as a fixed point, it would be possible, figuring from period to period, to determine the sex nature of the ovum to be discharged at each following menstrual period. Account is taken of all regular periods during the time menstruation is suspended in pregnancy. Thus, conception may be timed in such a way as to impregnate at will a male or female ovum.

This solves in a simple, rational manner another of Nature's riddles, namely, the reason for the practically equal division of the sexes.

SECTION XXXIV

Prenatal Influence

There exists just as much diversity of opinion among scientists concerning the reality of prenatal influence as about race heredity, use heredity, disease heredity and many other mooted problems of science and philosophy, which we shall study in Vol. IV of this series. In the following I shall present and examine impartially the various theories and opinions concerning prenatal influence; then we shall be better prepared to draw our own conclusions.

1. Medical Science Denies Prenatal Influence. Medical men, as usual cocksure of the correctness of their theories and hypotheses based on the "latest discoveries", deny and ridicule the possibility of prenatal influence, and relegate it to the rubbish heap of popular superstitions. They base their judgment on the fact that no nerves pass from the body of the mother through the umbilical cord into the growing fetus in the placenta, which forms the soft protecting nest of the new life within the womb. They claim that since no direct nerve connection exists between the two, mental and emotional vibrations cannot be transmitted from the brain of the mother to the brain and nervous organism of the fetus.
Are there no other means of communication between the mind of the mother and the brain of the unborn!

In the volume dealing with Eugenics we shall learn how universal intelligence and creative will become individual intelligence and personal will.

Cosmic vibrations do not flow into the gray matter of the human brain over coarse physical nerve tracts. They come over the psychical wireless which connects the human soul with the world Soul, the individual intelligence with the universal or cosmic intelligence the human will with the divine will.

Since, as proved by modern brain and nerve anatomy, immaterial cosmic intelligence and "power to will" fashion the brain of the mother into physical material centers for the expression of human intellectual faculties, capacities and powers, why cannot these cosmic vibrations act in like manner over the psychic wireless through the soul and mind of the mother on the brain and nervous system of the fetal organism?*

These epoch making discoveries and revelations of modern brain anatomy are explained in Vol. IV of this Series, *Natural Eugenics—Man Building on the Physical, Mental and Moral Planes.*

Why should the wireless, which transmits impulses of intuitive intelligence from the great source of all intelligence and creative energy into the soul of the mother, cease to operate at that point, and fail to transmit its message to the brain and nervous system of the fetus which is most intimately related and connected with the organism of the mother?

What about the phenomena of hypnotism? Absolute control of the subject's mind, through the intelligence and will of the hypnotist does not depend upon the existence of an umbilical cord and physical nerve connection between the two. The hypnotist, by silent command, may call his subject from a distance, far beyond the reach of his voice.

People telepathically attuned may communicate in like manner, spontaneously, or by conscious intent. Why then should we doubt the possibility of vibratory correspondence between the mental and emotional conditions of the mother and the plastic nervous organism in process of development within her womb?

If a complexity of sound can impress itself permanently upon the wax cylinder of a phonograph, or what is still more marvelous, if the photographic rays of passing scenes can be fixed and retained in the picture film, why should it be impossible for the mental and emotional vibrations of the mother to impress and modulate the molecular and cellular constituents of the fetal brain and nervous organism?
I have compared this creative power of the mother mind to the process of electrotyping. As the particles of metal in suspension in the fluid adhere to the spoon that is to be coated with silver, so the atoms and molecules in the gray matter of the brain of the fetus group themselves in harmony with the thought forms and emotional vibrations of the mind and soul of the mother. While this mental and psychical electrotyping takes place automatically, the mother's brain and nerve molding power can be greatly strengthened and intensified by the conscious and voluntary operation of the psychical wireless that establishes vibratory oneness between her and the human entity in process of development within her own body.

Thus it is revealed how a brain prenatally refined, organized and fashioned may endow the nascent individuality with certain aptitudes and talents along established paths of cerebration. There surely will be less resistance along such lines of physical, mental and moral endeavor than along other lines not prenatally influenced and molded. Therefore I strongly advise mothers, pregnant with new life holding marvelous possibilities for good or evil, not to be influenced by the superficial reasoning of materialistic science, but to follow the sacred intuition and impulse of their own creative genius in this, the most holy function of their being. Every normally constituted mother is intuitively aware of this wonderful power, and is willing and anxious to exercise it when her consciousness has been aroused to the great possibilities and responsibilities which the divine privilege of motherhood confers upon her.

It is natural for us to admire a great artist who portrays the human form, true to life, on the painted canvas, or who fashions it from inanimate stone, metal or marble; how much more grand and godlike is the creative power of truly mated parents whose privilege it is to bring into the world, and to fashion according to their highest ideals, a human being endowed with life and intelligence, with the infinite possibilities of a new center of creative activity.

Yet many mothers, totally ignorant of their divine creative privileges and possibilities, victims of physically and morally degrading marriage relations, and often filled with secret aversion or open hatred for their marital companions, pass unwillingly through pregnancy and not infrequently seek to destroy the new life. When the unfortunate victim of such marital incompatibility, conceived in passion and developing under the worst possible influences of mental and emotional discord, comes to arouse the maternal instincts of affection and devotion, then fear, anxiety and worry, like a continual nightmare, haunt the unhappy mind of the mother and impress their discordant vibrations upon the sensitive films of infant consciousness.

Compare this condition of fear, apprehension and gloom in the mind and soul of an unhappy and unwilling mother, with the joyful and ecstatic state of mind of a mother conscious of
the creative power of her intelligent will, who, from the time of mating and procreation, with accurate prescience prepares the most favorable conditions, astrologically, prenatally and postnatally for the finest development of the physical, mental and moral characteristics of the future world citizen.

The loftiest exaltation of a creative genius working in dead clay and cold marble cannot approach the ecstasy of a mother who has acquired a knowledge of the great laws which make possible the development of a perfect human being, the embryo of a master, an angel, a being destined to be godlike in its faculties, capacities and powers!

In place of fear and anguish of soul, what joy to the mother who knows that it lies within her power to prevent disease and degeneracy in her offspring; that the development of the child depends solely upon her own intelligent effort! Nothing is left to accident. Child bearing becomes an exact science, the most beautiful and inspiring of all arts and professions. Under such conditions motherhood, instead of being the greatest of hazards and hardships, becomes a divine privilege and the highest achievement of human existence and endeavor. It falls short only of the creative work of the great Universal Intelligence whose instrument of creation is the mother.

2. An Example from History. Let us consider the oft-quoted example of Napoleon Bonaparte. His mother, Lutitia Bonaparte, while pregnant with the future military genius, accompanied her husband on a military expedition, sharing with him the hardships and excitement of camp life, and the marches and battles of a military campaign. If there be nothing in prenatal influence, is it not singular that Napoleon should have become one of the greatest military geniuses of all ages, while not one of his many brothers ever exhibited enough military ability to make an efficient corporal? What was it that favored or determined the birth of the great military prodigy under these circumstances? The ancestors of Napoleon's father were not professional soldiers, nor was the father especially interested in military matters before the conception of his gifted offspring.

The dominant influences, therefore, must have operated through the singular occupation and surroundings of the mother during this particular pregnancy.

Many similar striking examples have been cited in works on prenatal influence. I myself might add many convincing proofs from an extensive experience in medical practice; but time and space do not permit. Contributory evidence may be secured from many excellent works dealing with this vital problem in human life. I may be permitted to say that use heredity and prenatal influence are distinctly manifest in the physical and mental characteristics of our three children who were born at intervals of seven and five years. Each one of them clearly mirrors in his or her physical, mental and emotional peculiarities the predominant mental tendencies, occupation and surroundings of the parents during the
respective prenatal periods. Similar manifestations of prenatal influence may be observed in almost any family.

3. Birthmarks. Medical men of late deny also the possibility of "marking" the offspring by sudden fear or shock on the part of the mother during pregnancy. Incidents of this kind, however, are of such common occurrence that it is a waste of time to refute these flippant denials.

There are good reasons for believing that such marking is more likely to occur during the periods when the menstrual flow should take place, but is suspended.

It may be argued that to mention the possibility of marking to a pregnant woman will greatly increase the probability of electrotyping violent emotions upon her offspring; in other words, that the fear of the thing will help to materialize it. This may be true to a certain extent, but we must remember that sudden shock through fear or disgust may cause the mischief anyway, whether or not the expectant mother is aware of the possibility. Understanding a danger and being prepared for it seems the best protection. The pregnant woman should study carefully section XXX, dealing with mental and emotional causes of nervous diseases, and should learn to relax to any sudden surprise and thus neutralize unpleasant and fear arousing impressions. Self-control is the royal remedy and the key to mastership.

4. Physical Influence. Now that we have studied some of the more important hereditary mental and psychical prenatal and postnatal influences, let us see how the physical condition of the mother's organism influences the brain and nerve matter of the fetus in its last stages of development, and after birth.

Materialistic science teaches that brain matter exudes thoughts and feelings, as the liver excretes bile, or the stomach pepsin. Natural science proves that mind is superior to matter, that the new born ego, by the power of intelligent volition, must fashion in the gray matter of the brain the molecular groupings or centers for the expression of intellectual and emotional activities, such as language, music, numbers, scientific and philosophic speculation.

This means that active cerebration and brain molding do not begin until after birth. But it stands to reason that the work of the nascent intelligence may be greatly facilitated or impeded by the physical condition of the brain. It is reasonable to assume that intellectual and emotional vibrations will more easily shape the gray matter of the brain into new configurations when it has been prenatally refined, organized and developed along certain lines of cerebration by use heredity and by constructive prenatal influences.

There exists a remarkable similarity between the brain molding and memory building activities of the intelligent ego and the making of phonographic records and moving picture
films. Lifelike impressions of sounds and passing scenes can be made upon the phonographic and photographic mediums only when wax and film are in a highly refined and plastic condition. When impure of substance and coarse of texture they, are not sensitive and plastic enough to register and retain the subtle and highly complex vibrations of sounds and passing scenes. In order to receive and register a great variety and complexity of sounds, the wax on the phonograph cylinder must possess a certain degree of refinement, softness and plasticity. If it is too hard and coarse it registers the loud and coarse sounds only. Such a record cylinder, exposed to a beautiful symphony executed by a great orchestra, would register and reproduce only the shrill cries of the trumpet, the rattle of the snare drum and the booming of the big horns and bass drums. The softer sounds of string, wood and wind instruments and finer shadings of tone and rhythm would be lost. With increasing refinement and plasticity, more subtle and delicate sound vibrations will be retained and reproduced.

In like manner the sensitive gray matter of the cortex of the brain must be in a pure and plastic condition in order to receive and register the impressions and impulses coming through the sensory organs, the psychic intuition and the intellectual and emotional activities of the mind. Anything in the way of physical impurity or foreign matter that tends to clog the brain, or to feed it with waste and morbid materials, or with corroding poisons, will lessen the atomic and molecular motility of brain and nerve matter, and will interfere with, or impede, the groupings and subtle transformations involved in the fashioning of brain centers through mental and emotional influences.

If the nutrient blood which feeds the brain substance of the fetus be saturated with CO₂, the benumbing, paralyzing carbon-dioxide, with clogging uric acid or the destructive acids of phosphorus and sulfur, the gray matter cannot respond to the subtle and complex impressions and impulses from without and within.

The purity or impurity of the plastic matrix of the cortex depends upon the materials absorbed from food and drink. If these are so constituted as to create in the system excessive amounts of clogging and corroding substances, then these food and drink poisons will have a benumbing and deteriorating effect upon the sensitive gray matter of the brain, as well as upon the coarser tissues in the joints, muscles and vital organs. There is a rheumatism of the mind as well as of the joints.

A brain asphyxiated and clogged with pathogenic materials cannot be alert and active; it is too dull and lazy to think; it would much rather sleep than work; it is incapable of doing its best when its tiny blood and lymph vessels are obstructed with waste and morbid deposits which prevent the oxygenation and drainage of its delicately organized cellular tissues.
This, of course, is true postnatally as well as prenatally. A brain originally capable of the highest and finest achievements of the human mind may become utterly worthless, and may degenerate into idiocy through food, drink and drug poisoning.

Medical men tell mothers they need not worry over prenatal feeding, because the placenta, the vascular bag which forms the nest of the new life, acts as a filter which purifies the blood before it reaches the fetus. Common sense and every day experience tell another story. Even the best in the blood of many mothers is bad enough to serve as food for the new life.

The placenta does not filter out of the blood of the mother all food, disease and drug poisons. This is proved by the wretched condition of many infants, suffering from malnutrition, anemia and rachitis, after delivery. If the vital fluids of the mother are deficient in the mineral elements, or in other important nutritive substances, how can they deliver them to the fetus?

Occurrences like the following, quite common in our institutional practice, prove positively that the placenta is not a perfect filter for systemic poisons and for disease taints circulating in the blood of the mother.

One of the most pitiable cases of eczema in a little child less than one year old we traced to the fact that the mother, during her first year of marriage, had traveled with her husband through Eastern European and Asiatic countries, and during her pregnancy had been vaccinated five times while passing through localities where smallpox was prevalent. Both she and her husband had always enjoyed perfect health. The family record was excellent as far as traceable; still the body of the infant soon after birth, was covered with open bleeding sores, presenting a revolting sight. We could find no explanation for this strange phenomenon other than the many vaccinations during pregnancy. These had contaminated the blood of the mother, and through her the body of the fetus, with a filthy scrofulous taint.

The baby suffered terribly. For many months it slept but little, because of the excruciating pains. The eczematous eruptions were of a very stubborn nature; they broke forth again and again. Finally, however, after eighteen months of natural treatment, we succeeded in purifying the little body of the horrible infection. The child is now a little over three years old, in perfect health, and during the last twelve months has shown no signs of the morbid taint.

Under another section I shall describe the influence of food upon character and sex life.

To recapitulate: Purity, plasticity and motility of the highly refined and sensitive materials which make up the gray matter of the brain depend upon pure food, plenty of fresh air and exercise, and upon all other natural methods of living
1. Conception takes place whenever the male spermatozoon joins the female ovum (egg) within the woman's womb. Normally the female organism liberates from its ovaries but one ovum each month, usually during menstruation, while the male discharges millions of spermatozoa at each orgasm.

Conception does not always follow copulation. The ovum remains in the womb and is capable of impregnation for about five days after menstruation. The spermatozoon on entering the womb may meet an ovum which has been discharged at a previous menstruation, or it may remain alive in the womb for a number of days and finally come in contact with a newly discharged ovum at the following menstruation.

The spermatozoon retains its ability to impregnate the ovum for from ten to fifteen days after its discharge into the womb. When the male and female germs merge into one another, conception or impregnation takes place. As soon as this has happened, the impregnated ovum becomes attached to the inner lining or mucous membrane of the womb and begins its new life as an embryo. The period comprising the time from the impregnation of the ovum until the beginning of labor or childbirth is called pregnancy.

The table of pregnancy on page 377 indicates the probable date of normal termination of a pregnancy, calculated from the last menstruation.

2. Exercise During Pregnancy. Unfortunately a great many expectant mothers labor under the idea that they must rest and be relieved from work and exercise. This of course is a great mistake. Light housework is good exercise. There is nothing more harmful during pregnancy than nursing "that tired feeling" by lounging idly about the house and coddling one's real or imaginary aches and troubles.

Of great benefit to the pregnant woman are all outdoor sports such as tennis, golf and other games which require vigorous exercise without straining or overworking the body. The great benefit of walking and other outdoor exercises, aside from their general invigorating effects, lies in the strengthening of the abdominal muscles and ligaments, which at delivery will greatly facilitate expulsion of the fetus.

The walk should be brisk and rhythmical, body erect, head thrown back, chest forward; the breathing at the same time should be deep and regular. These walks should be continued as long as time and endurance permit. Nothing, of course,
must be pushed to the point of exhaustion. One good long walk every day is necessary; two are better.

We all understand the necessity for a plentiful supply of oxygen under ordinary conditions, and especially in time of illness. During pregnancy the demand for oxygen, as well as for mineral salts, is doubled or trebled on account of the needs of the rapidly developing organism in the womb of the mother.

These extra demands for oxygen and ozone must be supplied by systematic deep breathing, cold bathing, outdoor walks, etc. If circumstances do not permit the taking of outdoor exercise, deep breathing should be practiced as often as feasible, at the open window.

Next in importance among gymnastic exercises is the internal massage described under section XXI, No.16.

Those exercises are especially valuable which bring into play the abdominal muscles and the muscles and ligaments of the genital organs.

3. Clothing. Clothing and the manner of wearing it profoundly influences the normal or abnormal development of the fetus, the health of the mother, labor and delivery.

At no time should the waistline be constricted by a corset or even by the ordinary skirt band. All clothing should be as loose and light as possible—one-piece under and outer garments, with the weight suspended from the shoulders, are best. If skirts are worn they should be fastened to skeleton waists of some thin cotton material. The close, heavy texture of the material from which the corset or so called "reform waist" is made is injurious because it interferes with skin elimination.

Even the slightest constriction of the waist line interferes with the free circulation and the normal blood supply to the abdominal organs, which is of especial importance in pregnancy; it also hinders the free expansion and movement of the uterus during the various stages of pregnancy.

Within the waistline are located a dozen or more important vital organs of the body. Any sort of constriction compresses these organs and pushes them out of their normal position. While this is extremely injurious to the body of a woman under ordinary conditions, it is doubly so to the pregnant mother and to the rapidly growing fetus. Undoubtedly many deformities and monstrosities are produced by unnatural constriction of the blood vessels and vital organs in the abdomen and pelvis of the pregnant woman.

If due attention is paid to the foregoing influences, labor and delivery will be brief and easy. This we have proved in hundreds of cases which have come under our management. The reason why women of civilized countries spend many
hours and sometimes days in dreadful agony of childbirth while those of primitive or savage races, as we call them, produce their young easily and painlessly as the animals do, is that primitive women live more simple and natural lives, while "civilized" mothers violate practically every law of Nature in their daily habits of living.

Civilization unfortunately stands in many respects for that which is artificial, unnatural and therefore productive of disease and suffering in all domains of life, not only as regards physical health, but social and political health as well.

SECTION XXXVI

Danger Signs During Pregnancy

1. Dropsical Swelling. Swelling of the limbs and distention of the veins of the legs during pregnancy may be caused by a tendency towards varicosity, intensified by obstruction of the circulation due to the enlarged uterus. Such a condition requires, aside from the natural regimen, careful and competent treatment.

Swelling of the limbs or other parts of the body may also be caused by incipient or advanced Bright's disease. The urine should be examined from time to time, especially if there is a swelling of the feet and ankles, or if there are dropsical symptoms in other parts of the body.

Such dangerous conditions are usually brought about through the excessive intake of starchy and protein foods which overwork the liver and kidneys and cause pathogenic dogging of the capillary circulation. This may result in uremia attended by violent and sometimes fatal Convulsions.

2. Uremia is the result of retention in the system of waste materials and poisons that should be eliminated through the kidneys and skin. Medical treatment for such conditions, aside from the administration of stimulating drags, consists in hot bathing with the idea of opening the pores of the skin.

We understand that all hot water treatment gives only temporary relief and is followed by greater enervation and inactivity of the skin. The best water treatment for systemic poisoning of any kind consists in the application of wet packs followed by cold ablutions as described in section XV.

The addition to the packs, dry friction rubs, air bath, good massage and neurotherapy treatment will aid in restoring the normal activity of skin, bowels and kidneys.

Whenever the urine contains sugar or albumen, fasting, alternating with raw food diet, is indicated. Suitable regimens are outlined in sections X, XI.
The giving of heavy food to the mother with the idea of increasing the flow of milk is all-wrong. We have found in all cases that the diet outlined in section X will produce a more copious flow of rich milk than lie "nourishing" meat diet. The best remedy for a scanty flow of milk is slow and thorough mastication of a few spoonfuls of raw crushed wheat every day.

3. Morning Sickness. One of the common disorders experienced during pregnancy is that known as Morning Sickness. One suffering from this ailment, though following a natural diet, should sip a cup of hot postum while remaining in bed. If this does not have the desired effect and if the patient has not been accustomed to drinking coffee, half a cup of black coffee with a few drops of lemon juice will quiet the irritated nerves. It is necessary after taking the hot drink to remain in bed for at least thirty minutes. It is understood that this is only an emergency measure. If continued, it will lose its good effect and work injury.

SECTION XXXVII

Labor and Delivery

At about forty weeks, exactly nine solar months, from the period of conception the fetus reaches full maturity, and labor begins. Labor is divided into three stages. During the first stage the neck of the womb becomes slowly and gradually distended and the orifice of the womb opens widely. When this has taken place, the fetal membranes burst and the amniotic liquid surrounding the fetus escapes.

During the second stage the fetus emerges from the womb.

After expulsion of the fetus, the placenta is expelled from the uterine cavity. This constitutes the third stage of labor.

The first stage usually begins with more or less radiating pains in the abdomen, accompanied by dull pain in the small of the back and a drawing pain in the limbs. Sometimes women with the first baby feel these pains weeks in advance of the actual commencement of labor. At first they occur at long intervals and are of short duration, but gradually become more prolonged and more frequent. The pains are due to a cramp-like contraction of the muscular apparatus of the uterus forcing its contents downward.

Under this pressure from above, the neck and mouth of the uterus distend to their limits, and the walls become thinner and thinner. First the inner, then the outer orifice of the neck of the womb opens and the fetal membranes protrude and finally rupture, allowing the amniotic fluid to escape. Shortly after this the part of the fetus nearest the orifice, normally the
head, makes its appearance. At the present time the average duration of the first stage of labor is six hours, but it may last twenty-four hours or longer, depending upon the plasticity and elasticity of the bony structures of mother and infant, the rigidity of the cervix, and the vigor or lack of vigor of the muscular apparatus of the uterus.

While the foregoing is true of the average delivery under ordinary ways of living, we find that after the enforcement of a natural regimen of living during and, better still, before pregnancy, the entire period of labor and delivery does not cover more than half an hour, or at the utmost from one to two hours. Even the disadvantages of slight build and smallness of pelvis can be overcome by the natural regimen outlined in section X. When our youngest child was born, the mother gave the first sign of pain at about midnight. I rose from bed instantly, but had not time to finish clothing when the membranes broke. Within twenty minutes after the commencement of labor the infant was resting in my hands.

The wife of a prominent lawyer in a western city had experienced three difficult deliveries. Each time surgical instruments had to be used and she had suffered untold agonies lasting from 24 to 36 hours. When she became pregnant the fourth time the most prominent physicians in her home city assured husband and wife that it was not safe for her to go through another delivery, that the womb was in worse condition than ever before therefore they recommended surgical removal. For conscientious reasons, however, the husband and wife did not follow the advice of the doctors, but decided to try natural methods of treatment.

The lady placed herself under our care during the fifth month of pregnancy. From that time on she followed strictly the natural regimen of living and received daily the usual hydropathic and manipulative treatments. This was continued until a few weeks before delivery. In this case the baby was born within an hour from the first contraction, and the mother of the patient, who was in an adjoining room, had not heard a sound. Many similar experiences refute the idea that it is unsafe and injurious for pregnant women to undergo the ordinary methods of natural treatment, such as hydropathic sprays, sitz baths, massage, Swedish movement and other forms of manipulation.

1. Preparation for Delivery. The diet during the last week before the beginning of labor should be very light, consisting mostly of fruits and vegetables. From the commencement of labor no food at all should be given, until at least twenty-four hours after delivery; a three-day fast is better.

In addition to a competent physician, a nurse or midwife should be engaged. If a good neurotherapist, who has had sufficient experience in obstetrical work, can be procured, he should be preferred, because he can assist delivery and make it much easier by manipulative treatment.
The nurse will make the necessary preparations and provide the various supplies needed in labor. With the first sign of approaching labor, the physician in charge should be summoned. A rectal enema of one pint or more of warm salt water (See. XVIII, No.4) should be administered. The woman should be given a vigorous cold rub and her genitals thoroughly cleansed. She may then remain on her feet and walk about, comfortably dressed, until actual labor commences.

2. **No Anesthetics.** The attending physician should not be impatient to hasten delivery with drugs or instruments. The use of anesthetics should be avoided insofar as this is possible. They should be employed only when absolutely necessary—that is, when excessive pain must be allayed or when surgical delivery is unavoidable.

3. **Breaking of Water Bag.** When the bag of water is about ready to break, the patient is placed in bed. Premature discharge of the amniotic fluid must be guarded against. An escape of the liquid at an early stage means difficult and prolonged labor, commonly known as "dry labor". Usually the membranes burst when the orifice is fully dilated. A large sponge is held in readiness to catch the out-flowing liquid.

3 a. **Umbilical Cord.** When the infant has been delivered, the umbilical cord should not be severed at once. Plenty of time should be allowed for the blood to transfuse itself from the body of the mother to that of the child. This is important. If the connection is severed too soon, the child begins life in an anemic condition.

The newborn baby usually greets the world with a lusty cry. It should be placed on its right side with its face turned away from the mother, care being taken that the cord is not stretched tight. As soon as the cord stops pulsating, plenty of time being allowed for blood transfusion, it is tied about two inches away from the baby's abdomen and cut a little above the ligature. The baby is now wrapped in a warm blanket and put in its crib.

4. **After Delivery.** Immediately after the baby is born, the nurse or attending physician gently compresses the abdomen and womb of the mother, kneading and rubbing it occasionally in order to secure complete contraction and thus prevent hemorrhage. After delivery the mother enjoys a period of rest and recuperation which usually lasts for about half an hour.

5. **Afterbirth.** Meanwhile the placenta becomes detached, and when the pains set in again a few contractions usually suffice to expel it with all the membranes.

The attending physician must make sure that none of it is left in the body, since this might result in putrefaction of the remains and blood poisoning. The woman's genitals should be washed with clean sterilized water.
The exhausted woman should now enjoy a deep, wholesome sleep and awaken from it in a few hours refreshed and strengthened.

In the foregoing I have not gone into the details of obstetrics and of technical management because this must be left to a competent obstetrician. I have called attention only to those points which are of special importance from the viewpoint of Natural Therapeutics and to the differences in treatment between the conventional and natural methods.

6. The Lying-In Period. The lying-in period varies from five to twelve days, according to the constitution of the mother and the care that she has taken during pregnancy. The greatest danger of the lying-in period is puerperal sepsis or blood poisoning. This condition is the result of infection occurring during labor, or it may result from the retention of parts of the placenta.

The only way to prevent this is by observing the most scrupulous cleanliness during the entire process of childbirth and during the lying-in period. When blood poisoning has developed it must be treated the same as all other acute inflammatory diseases (see section IX).

7. Care of the Newborn. The child should begin to breathe immediately after the cord is cut. If it fails to do this, the physician should lift the baby by its feet to facilitate the escape of mucous from the trachea and throat. If necessary the mucous must be removed from the throat by the insertion of the little finger, or by means of a tiny stick covered with gauze.

Breathing may be accelerated effectively by a few sharp taps on shoulders and buttocks. If this fails to bring the desired result, artificial respiration must be resorted to at once. The attendant grasps the child by its shoulders, its head resting between his palms and the two index fingers being hooked under the child's armpits. It is now swung between the physician's legs and lifted high above his head so as to be turned upside down. This is repeated from fifteen to twenty times, after which it is placed in a basin containing a few inches of warm water. Its body should then be rubbed briskly with cold water.

Father Kneipp used to take the newborn babe by the nape of the neck and the feet and submerge it quickly in cold water. This, a few times repeated, is probably the quickest way of resuscitating an asphyxiated baby.

In order to soften the cheesy deposit which frequently covers the body of the newborn, it is well to rub the skin with warm olive oil. After the greasy covering has sufficiently softened it may be removed with bits of gauze. This is followed by a cleansing bath with warm water and castile soap.
After the warm cleansing bath, the little body should be quickly rubbed down with cold water, wrapped in a soft, warm blanket and laid away to sleep until it wakens of its own accord. A normal baby should sleep for about twelve hours, and must not be disturbed to force food on it before it is ready to take it.

8. Bathing. From the first day, the baby must have a morning and evening bath. This consists, as before described, in a quick, cleansing bath of warm water and castile soap, followed immediately by a brisk cold rub. In the course of a few weeks the baby can be placed, for the cleansing bath, in a small bathtub containing a few inches of warm water. Immediately after the cleansing bath the warm water is replaced by cold water. This is taken up in the hollow of the hand and briskly applied to the little body. In this fashion the child, within a few months time, will enjoy its cold rub just as much as an adult. I have seen several such nature cure babies, but a few months old, object most vigorously to a warm bath. The cold rub is the best preventive of chilling; but care must be taken that the temperature of the room where the bath is given is not below 70 deg.

The olive oil bath or rub, often recommended for premature babies or infants suffering from malnutrition, is very injurious, because it occludes the pores of the skin and prevents the elimination of poisonous gases and other morbid materials from the body. The skin is not an organ of digestion. Olive oil, like all other foods, must enter the body through the alimentary canal where, under the action of digestive ferments, it is broken down into its component elements which are then assimilated through the intestinal membranes. Oil absorbed through the skin is not digested, and it circulates in the body as foreign matter which in this state cannot be assimilated and utilized in the system.

9. Powdering after the bath is fully as injurious as the rubbing with oils or massage creams. Powders and creams tend to clog the pores, and most of them contain poisonous antiseptics which lower the vitality of the skin and prevent or suppress elimination in the form of skin eruptions, eczemas, etc. For chafing use nothing but cold water. In case the chafing should become unusually severe and painful, through neglect by the caretaker, a soothing and healing lotion composed of one part lemon juice to two parts olive oil, may be applied a few times, until the irritation is under control.

10. Air Baths. Next to cold water, there is nothing that will invigorate baby’s skin and nervous system as will the air and sun bath. If the season will not allow the outdoor air bath, the baby should be allowed to lie nude several times a day, for thirty minutes or more, in a warm, well ventilated and sunny room.

11. Constipation. Glycerin and suppositories should never be used; neither laxatives nor cathartics. Oat extract and cooling sitz baths will produce natural movements.
12. **Diarrhea** is a form of morbid elimination, and must never be suppressed by drugs. If it is habitual, bailey or wheat extract prepared in the same manner as oat extract, is a good remedy. If the diarrhea is persistent and of a violent nature, no food at all must be given, except water with dilute acid fruit juices, until the purging ceases. Even then plenty of time must be allowed for the rebuilding of the sloughed intestinal membranes.

13. **Bandages.** Until the umbilical cord dries up and falls off, it is necessary to cover the navel with a gauze compress dipped in olive oil. This is held in place by an abdominal bandage made of soft cotton material. These strips should not be hemmed, merely torn or cut. They should be drawn just snugly enough to hold the compress in place, but not tightly enough to interfere with circulation. The navel must be cleansed and the compress renewed twice each day. After the umbilical cord has dropped off we no longer apply the abdominal bandage. This is contrary to common usage, but is the best practice. The abdominal bandage overheats the body and interferes with the free movement of the diaphragm and the circulation of the blood.

14. **Clothing.** The clothing of the infant should be loose and light and as simple as possible. Freedom of movement is very important; binding or pressure upon any part cannot help but interfere with the circulation, and otherwise produce injurious results. The clothes should be short, in order to allow the feet and legs free play. Light weight, porous cotton materials are best for both under and outer garments. A lightweight wool petticoat may be worn when absolutely necessary to provide sufficient protection for the baby. Cotton hose and bootees may be used, but under no circumstances should such articles be of wool, because it prevents free elimination from the skin. The baby's head should not be covered out of doors, except in severe weather. At no time should a veil be placed over the face, as it will cause the infant to reabsorb the poisonous exhalations from its own lungs. All clothing should be changed each day. No garment should be starched—such a practice is not only useless but harmful.

15. **Diapers** must be provided in sufficient number to allow thorough cleansing and drying. The wet diapers should be scalded in hot water and very thoroughly rinsed in several waters afterwards. They should then be dried in the open air and sunshine. Soiled diapers must be well washed and boiled. Washing powders, soda, ammonia and other chemicals should never be used. They have an extremely irritating effect upon the delicate skin of a baby. In order to save labor and to facilitate the cleansing of the diapers, small squares of clean old linen or muslin rags, or pieces of absorbent gauze, may be placed inside. These inserts will absorb all or most of the bowel movement and may then be burned. If the skin is irritated or chafed, the parts should be sponged off with clean cold water at each change, paying special attention to cleansing of the genitals. Oils or powders must not be used to soothe the sore places, because they clog the pores and
Interfere with natural elimination.

**16. A wet nurse** is to be preferred to artificial feeding. She should be thoroughly healthy, not over thirty years of age, of equitable temper, not excitable or nervous and her diet should be that prescribed for the mother.

**17. Care of the Nipples.** They should be thoroughly cleansed before and after nursing; not with carbolic acid, but with water and dilute lemon juice. The lemon juice tends also to harden the nipples. Treatment of the nipples may begin before the birth of the child.

**18. Care of the Eyes.** The baby's eyes, whether awake or asleep, should always be shielded from strong light, either sun or artificial, and from dust and wind. The eyes should be washed with cold water after every cleansing bath. If they show any tendency to weakness or disease, slight vibratory massage over the closed eyelids should be given after the cold eye bath.

**19. Care of the Mouth.** A healthy baby's mouth needs no cleaning before the arrival of teeth. As a matter of fact, the teeth of a perfectly healthy adult would not need cleaning any more than do those of an animal living in the freedom of nature. The saliva is a sterilizing fluid, under normal living, intended by Nature to keep the mouth clean and healthy. Cleansing of the mouth of an infant with the finger or with a cloth may injure its delicate membranes. If the mouth must be washed, in case of disease, a swab made by twisting a piece of sterilized absorbent cotton on the end of a smooth stick should be used. The swab should be dipped in warm boiled water, and the interior of the mouth washed thoroughly, the cotton then being burned.

**20. Care of the Ears.** The external ear should be cleansed with a soft rag or swab as before described. Never use a hard instrument inside the ear.

**21. Care of the Nose.** A baby's nose should be cleansed as a part of the daily toilet, in the same way as the ears. A swab may be made by twisting a piece of gauze to a cone. As soon as the child becomes old enough, it should be taught to sniff up cold water through the nostrils and the nasal passages. This is the best way to keep the nasal membranes in a clean, healthy condition.

**22. Care of the Genital Organs.** The genital organs of both sexes must be kept scrupulously clean with as little handling as possible. The foreskin of the penis of the male baby should be drawn back at bathing time and the organ thoroughly cleansed, always finishing with cold water.

**23. Phimosis.** The treatment of phimosis is fully described under Sec. XXVIII, No. 1.

**24. How to Lift the Baby.** The best way to lift a young
baby is to slip the left hand under the back beneath the shoulder, spreading out the fingers in such a way as to support the neck and head. Then lift the feet and legs with the right hand. Never lift an infant without first supporting the spine.

When a baby has grown strong enough to hold up its head and has gained considerable strength in the muscles of the back and neck, he may be lifted by grasping him with outspread fingers under the armpits; the body must be held firmly so that the entire strain does not come on the shoulders. A baby should never be lifted by the arms. This may dislocate the shoulder joints.

SECTION XXXVIII

Prenatal Feeding

1. Effects of Diet During Pregnancy. The problem of infant nutrition begins before birth. Prenatal feeding determines the physical start in life. On it depends not only the condition of the mother's health during pregnancy, but also the size and weight of the fetus, pliability of the bony structures, ease or difficulty of delivery, and the quality of the mother's milk.

The fleshier and heavier the newborn infant, the prouder and happier are the parents and the doctor. Yet, excessive size and weight of the child constitute the most prominent cause of difficult and painful childbirth and frequent necessity for instrumental delivery.

The biblical saying, "In sorrow thou shalt bring forth children"; has led many to believe that woman's dreadful suffering is a necessity, God ordained; but is not man's ignorance, rather than the cruelty of an avenging God, to blame?

This latter view is confirmed by the fact that other mammalia literally cast their young, without pain or difficulty; and the labor pains of primitive mothers are insignificant, their delivery presenting little more difficulty than that of the lower animals. A squaw on the Western Plains stops a few hours by the wayside to deliver her papoose and then resumes her journey as though nothing had happened.

Women among the European peasantry, who wear no corsets, live on black bread and vegetables, and have plenty of exercise in the fields and in the home to the last day of pregnancy, have their babies without help of midwife or physician and resume their usual routine of work within a few days after delivery.

Thousands of mothers who have adopted natural ways of
living have learned to dispense with anesthetics and the
surgeon's instruments; they now bring forth their offspring
without excessive pain.

2. Results of Faulty Diet. It is significant that the offspring
of the lower animals, at birth, consist of little more than skin
and bones, while the newborn human is often abnormally
large and fat. This is especially true of babies born of weak
and anemic mothers. As before stated, excessive size and
weight of the infant is not a matter for congratulation, but is a
pathological condition. It indicates fatty degeneration of the
fetus, due to the anemic watery condition of the blood of the
mother, and the cause of this hydremia of mother and child
lies in the faulty dietetic habits of the former.

The ordinary diet of American women consists almost
entirely of meat, fish, fowl, potatoes, white bread, pastry,
coffee, tea and refined white sugar. The few vegetable, which
enter into the daily dietary are first deprived of their all
important organic salts by faulty cooking; fruits are looked
upon as luxuries and frequently are regarded as harmful

The anemic, watery condition of the blood of mother and
child is not due to a lack of starchy, protein and fatty materials
in food and blood, but to a deficiency of organic mineral
elements. Neither is the anemic condition, as the regular
school of medicine assumes, caused by lack of iron. Any
ordinary food mixture, as well as the blood and milk of
anemic mothers, usually contains a sufficient amount of iron.
The actual cause of the anemia is a deficiency of other
mineral elements.

As I have explained in Volume III of this Series, carbonic
acid poisoning and the resulting sluggishness of the surface
circulation, coldness of the extremities and congestion of the
inner organs is not caused so much by a lack of the oxygen-
carrying iron as by a deficiency of the carbonic acid
neutralizing and eliminating sodium and magnesium.

If the blood is deficient in lime, phosphates, silicon and
fluorine, rachitic conditions, softening of the bones, deformed
spines and legs, and decay of the teeth, are inevitable results.

It is an easy matter to supply the daily needs of the
organism for proteids, starches, fats and sugars; the difficulty
lies in supplying a sufficient amount of the organic mineral
elements.

The deficiency of sodium in human blood, Dr. Lahmann
proved in the following table of comparative blood analyses.
In a hundred parts of ash he found in the

The percentages of lime and of other positive mineral elements in the human blood are also much lower than in the blood of cows, oxen and sheep.

While the blood of cattle and sheep raised on pasture is very uniform in composition, hardly any two samples of human blood are alike. It is for this reason that Dr. Lahmann adopted cow's milk instead of human milk as the standard elementary food combination.

In the following table, he compares the percentages of minerals in the ash of cow's milk with the percentages of mineral elements in the ash of various other food materials.

A daily dietary consisting largely of meats, eggs, white bread, potatoes, peas and beans, though excessively rich in proteids, fats and starches, will, on account of its deficiency in sodium, lime and magnesium, inevitably result in carbonic acid poisoning, anemia, rachitis, premature decay of the teeth and a multitude of other acute and chronic ailments.

If, however, the daily dietary contains a liberal amount of green vegetables and fruits, a normal food mixture resembling that of cow's milk can easily be obtained. It must be remembered that fruits and vegetables are not only rich in the most important mineral salts, but that they are relatively poor in proteids and carbohydrates.

For this reason fruits and vegetables facilitate the establishment of an equilibrium between proteids and carbohydrates on the one hand and organic mineral salts on the other.

3. Excessive Fat Formation. We can now understand why the ordinary faulty diet of pregnant mothers causes anemia, softening of the bones, sluggish circulation, carbonic acid poisoning and fatty degeneration in mother and offspring.

Lack of sodium causes excessive accumulation of carbonic acid, and oxygen starvation. This results in defective
oxidation of food and waste materials; in other words, in fat formation.

Defective draft prevents the complete consumption of coal, and chokes the furnace with the products of imperfect combustion. Similarly, lack of oxygen in the tissues (due to carbonic acid poisoning) causes an incomplete combustion of food materials and waste products, resulting in fat formation and in the generation of poisonous byproducts.

Lack of sodium also prevents the neutralization and elimination of uric and other acids and ptomaines (pathogenic matter) which accumulate in the tissues, block the circulation and assist in the smothering of the vital processes.

In order to eliminate these pathogenic materials, there arises an abnormal craving for water—"the anemic thirst"—which is closely related to the thirst of fever patients and of diabetics. Excessive water drinking is encouraged by the popular "flushing" fad.

To make things worse, the anemic, for reasons before stated, usually suffers from weak heart action and sluggish circulation. This means defective elimination of water through the skin and kidneys, resulting in a watery (dropsical) condition of the tissues and fatty degeneration.

Not all anemic, carbonic-acid-poisoned mothers, however, develop a tendency to obesity. On the contrary, under certain constitutional conditions, they may become exceedingly lean, like the anemic, carbonic-acid-poisoned consumptive. Briefly stated, sluggish heart action and weak kidneys favor retention of carbonic acid and water in the tissues and thus make for fatty degeneration. Good circulation and normal activity of the kidneys may keep the system free from excess of water and carbonic acid, but excessive proteids in the diet may result in sulfuric and phosphoric acid poisoning. These destructive acids break down the tissues, rob them of their mineral constituents, and thus cause excessive loss of flesh and fat.

In both types of dysemia the blood of the pregnant mother is overloaded with poisonous gases, waste matter and the debris of broken-down tissues. The oxygen supply to the fetus is therefore very much impeded and we find that both fleshy and lean mothers produce babies of abnormal size and weight, ranging from eight to twelve pounds, while the normal weight of the newborn should not be more than six pounds.

4. Advantages of Natural Regimen. We know of many instances where mothers, after having given birth to heavy, fleshy babies, in subsequent births have reduced the weight of the new born to normal, and the pain of delivery to a minimum, by the adoption of a natural diet, plenty of exercise in the fresh air and systematic deep breathing.
The effects of a natural regimen are manifested in various other ways. The bony and muscular structures of mother and child are much more pliable and elastic, making parturition and delivery much easier. Pure blood, normal nutrition and abdominal exercises, walking and special gymnastics, greatly strengthen the abdominal and uterine muscles, thus facilitating expulsion of the fetus.

The morning cold rub, systematic deep breathing and general exercises, every day outdoor walks and right mental and emotional attitude are all of paramount importance in the regimen of pregnancy.

The Regimen for Wholesome Living, section I, is admirably adapted for all the needs of the pregnant mother.

SECTION XXXIX

Postnatal Feeding

Thanks to the educational influence of nature cure propaganda, a decided change for the better in baby feeding has taken place during the past ten years. Up to that time the "top cream mixture" was universally recommended by allopathic physicians and given to babies by trained nurses.

While in the meantime many physicians and nurses have adopted more natural methods, the "top cream mixture" is still too common and must be entirely abolished in order to safeguard the health of our little ones.

In the February, 1909, issue of the Nature Cure Magazine, I commented upon this subject as follows:

1. Bottle-fed Babies. Our food analyses disclose the interesting fact that the elementary composition of the ash of the milk of an animal is about the same as the composition of the ash of its body.

They also show that good cow's milk when normal comes closer to the requirements of the infant body than does inferior human milk.

Our tables of food analyses show that chemically the composition of cow's milk and of human milk is very much the same. Human milk contains a little less proteid and a little more sugar than cow's milk, and the latter is much richer in organic salts than the former. There is much more of the all-important sodium in cow's milk than in human milk and about twice as much calcium (lime) and iron (table p.100). This explains why rachitis is so common among babies, while never found among calves.

As we have learned, the elimination of poisonous acids
from the body depends on sodium. The building of the bony structures depends on lime; the oxygenation of the blood, on iron.

Many years of practical experience in the care of babies has convinced me that milk fresh from a healthy cow is greatly to be preferred, as nourishment for infants, to the impoverished milk of scrofulous mothers.* In this connection it is significant that one-half of all "civilized" mothers, thanks to unnatural food and drink, vaccination and poisonous drugs, are incapacitated for nursing their offspring.

* This may not be true in the future if our milk cows continue to be regularly subjected to tuberculin tests.

To one who has studied the comparative analyses of cow's milk and human milk, it is incomprehensible why the former, when given to infants, should be diluted and spoiled by large quantities of water, salt, soda and inorganic mineral lime (in the form of lime water).

This procedure, however, is still frequently recommended by physicians of the regular school. Undoubtedly, the great frequency of anemic and rachitic diseases, the darkening of the iris, appearance of scurf rim, and the signs of catarrhal conditions in stomach and bowels are caused by such unnatural feeding.

The following extracts are taken from an article entitled "Bottle-fed Babies", in the Ladies' Home Journal. It was written by Dr. Emelyn Lincoln Coolidge, of the Babies' hospital, New York. Thousands of mothers, on account of the high standing and excellent reputation of this family journal, undoubtedly have followed, without question or misgiving, the advice presented.

The formulas given below are for the average healthy baby, and are called "cream" or "top milk" mixtures.

"Food for the first month. With a spoon, or a tiny dipper which comes for this purpose, carefully skim off the top six ounces from a quart bottle of milk; to this add twenty-four ounces of water which has been boiled and cooled, and in which has been dissolved three teaspoonfuls of granulated or six of milk sugar; next add a pinch of bicarbonate of soda and a small pinch of salt; mix this all thoroughly, and pour enough for each feeding into ten separate bottle& Then cork the bottles family with cotton and either Pasteurize the milk or stand it on the ice.

"For the second month. Skim off six ounces of cream, then pour off three ounces of milk; add twenty-four ounces of water and the same amount of sugar, salt and soda as above; mix and bottle.

"For the third and fourth months. Cream, six ounces; milk, six Ounces; water, twelve ounces; barley or oatmeal gruel, twelve ounces; sugar, salt and soda as usual, etc.

Plain Milk Formulas

"Pour the entire quart of bottled milk out into a clean pitcher and then back into the bottle several times, thus thoroughly mixing the milk; then take:
"For the first month. Six ounces of milk, twenty-four ounces of barley-water, half a tablespoonful of granulated or one of milk sugar, a pinch of bicarbonate of soda; mix all well together and pour the proper number of ounces into separate bottles, and either Pasteurize or place on ice.

"For the second month. Nine ounces of milk, twenty-one ounces of barley-water, one tablespoonful of sugar, and a pinch of soda."

Physicians would never think of giving such advice as this, if they were acquainted with natural dietetics founded on exact and complete analyses made by food chemists of the nature cure school.

I have already called attention to the fact that food chemistry, whether practiced in allopathic colleges, in great sanitariums or by vegetarian food reformers, deals with proteids, starches, fats and sugars only, and leaves entirely out of consideration the all important mineral elements or organic salts of potassium, sodium, iron, lime and magnesium.*

*This was true at the time this article was published in the Nature Cure Magazine.

On these five positive mineral salts, as we have shown, depend all the important vital functions of the human organism, while proteids, starches, fats and sugars serve only as building and fuel material.

The digestion of the proteid and carbohydrate foods, as well as the elimination of the waste matter resulting there from, depends upon the positive organic mineral salts.

Study carefully these recipes for baby feeding, taken from the Ladies' Home Journal, and compare the mixtures with the analyses of cow's milk and human milk in the accompanying tables.

Let us consider the "top milk" mixture, prescribed for the first month. The cream rising to the top is almost pure fat. The all-important mineral elements plus the nourishing milk sugar and proteids remain in the skimmed milk, which is looked upon as worthless and fed to the pigs.

Our food analyses (see tables in Volume III, Cook Book) show that the ordinary brands of flour are almost devoid of mineral elements. Furthermore, one teaspoonful of barley to one pint of hot water does not mean much in food values. Where in these six ounces of cream (fat) and twenty-four ounces of barley water is baby to get the necessary amount of sugar for fuel material, of proteid for tissue-building, of lime for bone-building, of iron for oxygen-carrying, and of sodium, magnesium and potassium for the processes of elimination?

It seems that these deficiencies are intended to be overcome by baking soda, mineral table salt and the lime water, so generally prescribed by physicians. Many times I have demonstrated that inorganic mineral salts, with the possible exception of a little table salt, should not enter the animal or human organism, that these salts must first be organized,
made alive in the plant or animal cell, before they are wholesome food for animals or human beings. I have shown that, taken habitually in the mineral form, these salts accumulate in the human body, act as irritants and poisons and reveal their presence in the iris of the eye.

I fail to understand why the tender and sensitive organism of the newborn infant should be encumbered with inorganic minerals while cow's milk contains them in ideal form, made alive first in the grasses and grains, then still more highly organized and magnetized in the body of the animal.

It is bad enough to give mineral sodium, lime and table salt to an adult, but it is little short of criminal to give them to babies under the guise of foods and medicines.

The cream mixtures are readily digested, because there is not much to digest. The fact that infants thus fed cry for food continually is good evidence that their needs are not satisfied. Babies fed with this sort of slop grow fat for a while. The watery food inevitably produces fatty degeneration. This for a season swamps the little body with unhealthy fat. But the first crisis which happens along often takes away not only the unnatural fat, but the baby also.

The artificial mixtures contain entirely too much water in proportion to nourishing elements. The resulting malnutrition and the constant irritation caused by the inorganic minerals result in chronic diarrhea or constipation.

**The Right Way**

The best food for the newborn and growing infant is undoubtedly the mother's milk, provided that she is herself in fairly good health. Unfortunately, many mothers are unable to nurse their offspring, and if a healthy wet nurse cannot be secured, other food must be provided.

The best substitute for human milk, without question, is cow's milk, fresh, pure and undiluted, as it comes from the animal.

"Why", indignantly exclaims the trained nurse, when we give these instructions, "undiluted cow's milk is altogether too rich, it is indigestible for baby; if the milk is not boiled or pasteurized, germs and bacilli will surely create infectious diseases".

To this we answer: Our analyses show that the difference in composition between cow's milk and human milk is not enough to affect the infant. The danger lies not so much in overfeeding on "rich" cow's milk as in underfeeding on watery milk and cereal dilutions, and in poisoning the little body with inorganic minerals.

As regards germ infection and the necessity for pasteurizing the milk, the menace to health and life is greater through
malnutrition than through germs and bacteria. Germs we cannot escape, not even if we were surrounded on all sides by walls of air-purifying and antiseptic materials.\

*Since the foregoing was written we have learned that low vitality and morbid soil will develop perfectly normal microzyma into so called disease germs.

One of the foremost French bacteriologists claims that in the mouths of infants shortly after birth he has found almost every disease bacillus known to medical science.

William Osler; M.D., to whom the English language is indebted for the verb "to oslerize," says in The Principals and Practice of Medicine on page 151, in the chapter on Diphtheria:

"The presence of the Klebs-Loeffler bacillus is regarded by bacteriologists as the sole criterion of true diphtheria, and as this organism may be associated with all grades of throat affections, from a simple catarrh to a sloughing, gangrenous process, it is evident that in many instances there will be a striking discrepancy between the clinical and the bacteriological diagnosis."

In the first part of this sentence he states that bacteriologists regard as the sole criterion for the diagnosis of diphtheria the Klebs-Loeffler, or diphtheria, bacillus; in the last part of the sentence he admits that this bacillus is found in even slight catarrhal conditions, and he might add that it is found just as frequently in the mouth and throat of healthy infants and adults. This is a good example of "orthodox" scientific reasoning.

If germs and bacilli of themselves could destroy health and life, the human race would in a short time become extinct. Disease germs are omnipresent. They permeate the tissues of our bodies and in the intestinal tract swarm by millions. Whether they prevail depends upon natural resistance, or reserve force, and upon the disease soils in the system. The air we breathe is saturated with all sorts of disease germs or their microzyma.

Since baby cannot escape germ invasion, the real problem is how to increase the resistance of the little organism and how to purify it of morbid matter so that disease germs will not find anything to feed on.

Resistance depends largely upon proper nutrition. Diluted, watery milk, contaminated by inorganic minerals, is not a good nutrient; its nutritive value is still more reduced by pasteurizing or boiling. Heating milk or any other proteid food above 1500 F. coagulates the albumen, disorganizes organic compounds, precipitates salts and dissipates the life elements. This reduces the nourishing value and digestibility of the milk.

Nature does not provide the young animal with boiled or
pasteurized milk, and we should not lower food values by such methods.*

* It is now admitted that pasteurization and boiling kills "newly discovered vitamins" which are the "life elements" constantly referred to in my earlier writings.

I do not wish to intimate, however, that scrupulous care and cleanliness should not be exercised in the selection and handling of the milk.

Wherever possible, secure the milk of a single healthy cow that grazes on green pastures or is fed on normal clean food mixtures. Milk from cows kept in stables and fed on brewery and distillery slops and other refuse should not be used.

Every vessel and utensil with which the milk comes in contact must be carefully scoured, submerged in boiling water, drained and kept in a light, airy place.

The nursing bottle, after each feeding, must be taken apart and carefully scrubbed, inside and out, in hot water with an addition of a little soda. It should then be left in pure, cold water, until the next feeding time.

2. When to Feed. Physicians quite generally recommend feedings at stated hours, in fixed quantities.

This is altogether wrong, it establishes at once the stuffing habit, does not permit the development of natural desire and its regulation. The infant very soon becomes accustomed to eating at certain times, whether it really needs the food or not.

Food should not be given until there is an actual demand for it, which will express itself in real hunger. By careful observation and experiment the mother will soon learn to distinguish the ordinary crying of the baby and the desire for food expressed by it. If this practice of feeding only when there is a natural desire for food is strictly followed, the infant will soon establish its own regular feeding times, usually at intervals of about three or four hours in the daytime. The stomach digestion of a feeding of milk will require about three hours, therefore a minimum of that much time should be allowed between feedings after the first few weeks.

If the mother can nurse her baby, it should be put to the breast upon awakening from its first sleep, either before or after bathing and dressing.

The first secretion of the breasts (colostrum) is not really a food, but performs an important function in cleansing the intestinal tract and preparing the digestive system to properly digest and assimilate the milk when it comes, usually about the third day.

3. How to Feed. If artificial feeding must be resorted to, no food at all should be given, except a few teaspoonfuls of water, during the first twenty-four hours after birth. During
the next few days, cow's milk should be given, well diluted—about one-half milk and one-half filtered or boiled water. From week to week the amount of water should be reduced until at the end of the second month the baby takes cow's milk undiluted.

4. Night Feeding. In the nighttime feeding should not be encouraged. During the first four months it is advisable to feed not more than once during the night. After that the child should be weaned from the habit entirely. This will be facilitated by giving a drink of water instead of milk.

5. Amount of Food. Discretion should be observed in determining the amount of food. Do not induce the baby to take as much as possible, rather as little as possible. Its welfare does not depend upon the amount of food consumed, but upon the amount which it can easily digest and assimilate.

When more food is given than the digestive organs can take care of, the entire mass may ferment and sour.

6. Grain Extracts. If undiluted milk proves too rich, grain water may be added. In order to prepare this, take clean grain as it comes from the field, crush it in a hand grain mill or a new coffee mill, take three tablespoonfuls of the crushed grain to one pint of cold water, and boil on the stove for one hour; or in the fireless cooker for two or three hours, in which ease use a little more water at the start. While the gruel is boiling over the fire, add enough water to allow for evaporation and absorption. When thoroughly cooked, strain the gruel through a fine cloth or sieve. Add one tablespoonful, or more if necessary, to each milk feeding.

When baby is constipated, add to the milk, grain extract made from oats, and frequently cool the bowels with cold water. This will cure the most stubborn constipation. If the bowels are too loose, add to the milk, extract made from barley or wheat.

The small particles of hulls in the grain extracts improve digestion and evacuation, in a mechanical manner. They permeate the curds and keep them from coagulating too solidly, thereby facilitating the penetration of digestive juices; they also exert a mild stimulation on the walls of the intestines, thereby increasing the peristalsis of the bowels and evacuation of feces.

7. Baby's Natural Medicines. Fruit juices and scraped raw ripe pear or apple and the pulp of cooked fruits such as prunes or figs without addition of sugar or sweetening of any kind, are baby's finest medicines. They increase the supply of organic salts for blood, nerve and bone building and for purposes of elimination. They are nature's own cholangogues, laxatives, tonics and antiseptics. They keep the little body sweet and wholesome. All babies under our care receive fruit juices beginning with the second week.
During the first two months, give one teaspoonful of orange juice, grape fruit juice or prune juice, one hour before or after each nursing. After the second month, gradually increase the amounts of fruit juices and begin to add raw pear or apple scraped with a spoon or dull knife, or the mashed pulp of fully ripened peach or grapes.

8. Weaning the Baby. Nursing infants should be weaned from the breast after the eighth or ninth month. From the sixth or seventh month, both nursing and bottle-fed babies should begin to take some solid food. The best of these to begin with are whole-grain cereals, gruels, raw and cooked fruits and tender vegetables in small amounts. Mealy baked potato is one of the best foods, better than the cereals.

9. Feeding After First Year. After the lapse of the first year, the solid foods are gradually increased and the milk reduced in quantity. Eggs should not be given before the eighteenth month, then soft-boiled or poached. During the second and third year half an egg twice or three times a week is sufficient; after that an egg at a time may be given once or twice a week.

Meat and all other foods prepared from the dead animal carcass are bad enough for adults, but it is inexcusable to give them to tender infants and children.

Dog fanciers, when they sell a valuable canine, usually advise the buyer not to give the animal any meat before the second year, lest it become a victim of distemper; and dogs are naturally meat eaters.

Well informed physicians now generally advise not to give meat to children before the fifth or sixth year. They have learned this much from the nature cure people.

Foods undoubtedly have a powerful influence, not only on the physical body, but also on the mentality and the emotions. These problems will be interesting subjects of investigation for the food chemist and psychologist of the future. In general, we may say that flesh foods are stimulating and feed the passional nature, while fruits and tender vegetables refine and stimulate brain and nerve matter as well as the intellectual, emotional and spiritual activities. Cereals, nuts and pulses build and repair the physical body and supply the body with heat and muscular energy.

The majority of animals adhere strictly to one kind of food, and therefore faithfully exhibit in their mental and emotional characteristics the effects of different food materials. Ferociousness we find personified in the carnivorous bulldog, lion, tiger and panther (that is why soldiers are fed on meat three times a day); gluttony and omnivorous voraciousness in the hog, chicken and hyena; cold-blooded cunning in the fox, and cruelty in the cat. The intelligence of the carnivorous animals displays itself mainly in the cruel cunning with which they stalk their living prey. It resembles in quality the low
intelligence of the human criminal.

Personifications of great physical strength, intelligence, endurance, patience, gentleness, fidelity, affection and self-control, we find among the vegetarian animals. The beaver, the arboreal ape and the elephant are especially noted for their intelligence; deer, antelope and sheep for gentleness; the horse for its almost human intelligence, affection and fidelity; oxen, elephants and camels for their great strength and endurance.

**Meat is detrimental to the child in every way**, physically, mentally and morally. The poisonous acids and alkaloids which it contains clog the capillary circulation, causing anemia, coldness of the extremities and defective elimination through the skin. This results in congestion in the interior organs, high blood pressure in brain and heart, headaches, nervousness, irritability, tendency to fevers, inflammations and catarrhal conditions.

With the meat, the child often absorbs the eggs of worms, tubercular bacilli, and other parasites and disease germs. Certain forms of epilepsy, St. Vitus' dance and hysterical conditions are due to uric acid poisoning and to other pathogenic materials and ptomains contained in flesh foods. Such patients, in times of crises, frequently emit pronounced odors of raw meat or uric acid. Strictly vegetarian diet, combined with other eliminative natural methods of treatment, cures the majority of these cases.

Most of these poisonous acids, alkaloids and ptomains contained in the flesh of dead animals are powerful stimulants. I have frequently noticed that people who have abstained from meat for a long time, when they first partake of it again experience sensations and exhibit symptoms resembling those of alcoholic intoxication.

We have learned that these stimulating extractives of flesh foods chemically closely resemble caffeine, thein and nicotine. The use of one or more of these stimulants invariably creates a craving for the others. This explains why a heavy meat eater is usually a confirmed coffee drinker or inveterate smoker, and vice versa; and why we find it almost impossible to wean people from one of these stimulants as long as they persist in taking the others.

The legumes or pulses—peas, beans and lentils—are close seconds to meat in acid-producing qualities. Eggs contain considerable ready-made uric acid and a great deal of sulfur and phosphorus. These may become dangerous to the organism. For these reasons, meats, legumes and eggs are always danger foods for the child.

Children brought up on such foods will show the effects in nervousness, irritability, lack of self-control, craving for cigarettes and alcoholic stimulants. The most serious aspect of this question lies in the stimulative influence of meat poisons
on the sex centers. It is a well known fact, verified by close
observation, that flesh foods stimulate the sexual passions to a
marked degree. This tendency is greatly increased by the use
of coffee, tea and alcoholic stimulants in the form of wines,
liquors or medicines. If the sensitive nervous organism of a
child is overwrought by these powerful irritants, there can be
but one result; precocious sexual awakening.

From the third year the child may gradually adopt with
slight appropriate modifications, a diet as outlined under Sec.
I, No. 10, and Sec. X, No.7.

SECTION XL

Exercises in Infancy

1. Exercises in Infancy. Proper exercise is important from
the very beginning of life. A baby will follow its natural
instincts for exercise if allowed to do so, by working its arms
and legs and writhing its little body in all directions, if not
unduly hampered by tight clothing and bandages. A few nude
air baths every day will afford excellent opportunity for
baby's gymnastic stunts.

After he is a few months old he may be placed on his
stomach, when he will exert himself vigorously by trying to
raise his head, to turn around, or to raise himself with his
arms. He will soon learn to roll over and to creep lie nay now
be pulled up gently by his arms and lowered again a number
of times in succession.

When three or four months old he may be lifted by one arm
or by both arms; by the right arm and left leg, or by the left
arm and right leg. When the baby is six or eight months old,
he should be strong enough to rise from his back to a sitting
position. This may be encouraged by holding down the feet. I
have known a number of nature cure babies who at six
months of age clung tightly to a stick while being lifted a few
feet from the bed. Another good exercise greatly enjoyed
by the youngsters is to roll them back and forth on a bed.

The average healthy child will secure ample exercise while
learning to walk and run and while playing with simple toys
or with other children; but this may be supplemented to good
advantage by special exercises devised by the father and
mother. Nothing is better for the health and happiness of both
parents and children than to join in merry romp and play.

Between two and five years of age the child may be taught
more difficult stunts, performed either by himself or with the
assistance of the father or mother; but swinging the child
high overhead, throwing him up and catching and other
dangerous tricks should be avoided. They are risky and
have very little effect in developing the body of the child. The
best exercise at this age consists in outdoor play and games.
From the sixth year, the question of exercise becomes a more important one, especially since the children are confined for many hours in school rooms. If exercise at this time of life, through play and games and special gymnastics, is neglected, it may affect health, strength and efficiency of the child for life.

Those of good physique and ample strength may gradually take up and practice the exercises for adults outlined in sections XXI, XXII, XXIII, XXIV.

2. High Chair. A baby should not be put in a high chair until he is quite well able to hold the spine and head erect, and should never be left in a chair for any length of time. If a baby is forced to maintain a rigid, sitting position for a considerable time, before the bones and muscles are sufficiently developed, this may produce deformity of the spine. Maids and nurses, if not properly supervised, sometimes fasten a baby in a high chair and leave him there to take care of himself for long periods.

3. Toys. Since most babies have a habit of putting everything into their mouths, toys must be selected that can do no harm. They should have no paint, no sharp points or corners which might hurt the eyes or mouth, and must be of material which can be easily and thoroughly cleansed. Hairy and woolly playthings are unsafe, being unclean and germ carriers. Objects small enough to be swallowed must never be put within baby's reach. The simpler the playthings the better; a few clothespins, empty spools, or other simple objects are better than expensive toys.

SECTION XLI

Baby's Ailments

1. Hernia As a result of a weakly or sickly condition of the mother during pregnancy and of faulty prenatal management, many children are born ruptured. So far I have not known a single nature cure baby that was born ruptured. Such defects are due to weakness of the tissues. This results from mineral starvation. The tissue walls contain too much mortar (protein) and not enough building stone (mineral salts). Prevention of hernia, therefore, lies mainly in proper diet of the pregnant mother, but all the rest of the prenatal regimen described in these pages is of great importance in preventing this and other ailments and deformities.

There are three principal points at which rupture or hernia may take place in infancy—at the navel, in the groin, and at the line between the navel and the lower end of the sternum. Other kinds of ruptures are extremely rare.
2. **Umbilical Hernia** This is a protrusion of the intestine at the navel. It is the most common rupture in infancy. Pulling on the cord during childbirth, urging at stool or violent crying may result in rupture. The umbilical ring first expands and this forms a pouch into which one of the folds of the small intestine protrudes.

Treatment: Of primary importance is the diet as outlined herein. The baby must have plenty of fruit juices in order to reinforce the mineral salts in the milk. Cold bathing is very beneficial. The rupture itself should be cleansed several times a day with warm water. This must be followed by a wash with cold water mixed with lemon juice. Gentle, passive exercise, such as raising, lowering and twisting the limbs from side to side, also raising and lowering the body while supporting the shoulders and head, is of especial value.

The rupture must be reduced and kept from protruding by placing over it a large button or other article of similar shape, wrapped in gauze and held in place by broad strips of adhesive plaster. The adhesive tape is fastened over the button crosswise and must be applied in such a manner as to draw the skin from all sides over the rupture. Instead of the button, a compress made of gauze may be laid over the rupture and held in place by one broad adhesive strip. The covering of the rupture must be removed and renewed every day in order to allow cleansing, as before described.

When the child is old enough to exercise by himself, he should be taught special movements of the body and the limbs which develop the muscles of the abdominal region.

3. **Ventral Hernia.** This occurs along the middle line of the body between the navel and the breastbone, sometimes below the navel. The rupture may not be larger than the size of a pea or small marble, and may disappear on pressure. The treatment is the same as that of umbilical hernia.

4. **Inguinal and Scrotal Hernia** occur in infancy or in adult life; sometimes the inguinal canal does not close after the descent of the testes from the abdominal cavity into the scrotum, and the intestine descends through the open canal, thus producing the rupture. These forms of hernia become aggravated by coughing. They can be reduced immediately with gentle manipulation while the patient is lying on his back. This kind of rupture may be distinguished from hydrocele by the fact that in reducing it goes back easily with a gurgling sound. Hydrocele is not affected by coughing. A hernia is opaque to transmitted light; hydrocele, transparent.

These ruptures should be protected with a well-fitting truss. This has to be removed daily for cleansing of the parts. Appropriate exercises, passive and active, together with cooling sitz baths and washes with cold water and lemon juice are the best remedies for these, as well as of other forms of rupture.
5. **Congenital Hernia** occurs in the form of inguinal hernia and has to be treated in the same way. Ruptures of any kind must be reduced and properly supported. Constipation and consequent urging at stool may cause or aggravate any form of hernia and must, therefore, be overcome by the right treatment described under section XXVI, No.1.

6. **Colic.** This is usually caused by indigestion due to overfeeding, improper feeding, or too frequent feeding. The intestines are distended with gas, giving rise to a severe pain. The baby cries sharply, alternately drawing its legs up to the body and kicking them away. One of the quickest means of relief is a small enema of warm water and gentle circular massage of the abdomen from right to left. Food should be withheld until the symptoms have disappeared. The giving of milk or other food may quiet the attack temporarily, but the pain is apt to return with greater intensity. Warm water may be given if the baby will swallow it.

A baby managed in the natural way prenatally and postnatally is not likely to suffer from this ailment. Constipated babies are more prone to it than others.

Colic may also be caused by sudden chilling. In that case a warm bath for five or ten minutes, followed by gentle body massage will bring about a warm reaction.

7. **Convulsions.** These cause a great deal of anxiety to the fond mother. They are always reflex symptoms of some slight or serious internal disturbance due to wrong management. They commonly result from some form of auto-intoxication caused by digestive disturbances, and the resulting systemic or drug poisoning. An inactive condition of the skin, bowels or kidneys will favor auto-intoxication and convulsions. If proper care is taken to keep the system pure, and the organs of elimination in active condition, convulsions will not occur.

The best treatment during an attack is a quick, cold rub all over the body; application of a whole body or trunk pack; gentle soothing magnetic massage, and neurotherapy treatment. These treatments draw the blood into the surface and relieve congestion in the brain and nervous system.

8. **Ailments of Teething.** Many ailments of children are laid to teething, but this is a mistake. Well managed, healthy babies go through the teething period without any trouble whatsoever. This is practically always true of nature cure babies. When, however, the little body is heavily encumbered with hereditary and acquired morbid materials, food poisons and disease taints, the process of teething will not run its natural course and may precipitate any form of disease crisis.

When teething is difficult, it is frequently associated with digestive disturbances. Diarrhea may alternate with constipation and vomiting is of common occurrence. The baby may be restless and fretful. He tries continually to bite on something in order to facilitate the projection of the teeth.
through the hardened gums.

No teething lotions or soothing medicines of any kind should be given for the relief of pain in teething. They all contain poisonous sedatives which benumb and paralyze the nerves and have serious after effects upon the system. They usually contain opium in some form, or other narcotic drugs.

The only way to prevent these and other infantile ailments is to keep the little body as nearly normal as possible through the natural treatment described in these pages. If this is closely adhered to, it will prevent, in many cases, the development of even measles and other common eliminative infantile ailments.

During this critical period in the baby's life the diet must be extra light; starchy food should be reduced to a minimum and replaced by raw and cooked fruits and vegetables juices. Cooling sitz baths will help to keep the bowels active and to abate internal fever.

9. Acute Catarrhal Disease. Acute catarrhal diseases of infancy such as croup, cold in the head, acute bronchitis and whooping cough, are different forms of acute elimination through which Nature tries to purify the little body from hereditary and acquired accumulations of morbid matter, systemic poisons and disease taints.

In accordance with this conception of acute diseases, as purifying, healing efforts of Nature, we would not do anything to check or suppress elimination but cooperate with Nature in her purifying, healing efforts. How we do this has been fully explained in other parts of this volume. (Section VIII)

The natural treatment is very much the same in all acute inflammatory ailments. Feeding must be reduced to a minimum. If the baby does not insist upon eating, nothing should be given except water with acid or sub-acid fruit juices, such as lime, lemon, grape fruit and orange. If the temperature does not run high, say not above 100 or 102 deg, frequent ablutions with cold water at intervals of from one to two hours will be sufficient to promote heat radiation and elimination of morbid matter through the skin and other organs of elimination. If the temperature runs' higher, say between 102 and 105 deg, wet packs must be applied, and renewed when they become hot or dry.

The wet packs are of especial value in all kinds of cough; whether it be the ordinary cough, croupy cough or whooping cough. A whole body or trunk pack, with or without a throat pack, will give almost instant relief. In many instances where baby is making the night hideous for the anxious mother, with it's coughing, a well-applied whole body pack, or a combination trunk and throat pack, will relieve the coughing almost instantly, and induce restful sleep.
In serious cases it is always advisable to call in a natural therapist or some other drugless physician, if one can be reached.

The mother should not forget that all acute diseases, after they have once developed, must run their natural course. She must, therefore, not become impatient and lose faith in the natural treatment if it takes a week or more to cure a common cold in the head or an attack of bronchitis, or if it takes from two to eight weeks to cure a case of whooping cough. Serenity, patience and cheerfulness are the primary requisites of the nature cure physician.

PART IV

BABY BOOK

Natural Therapeutics has undoubtedly solved the problem of treating human ailments. All other schools and systems will in time have to adopt the natural way. It is the hub of the healing art; all therapeutic methods radiate from it like spokes from a wheel.

Natural Therapeutics, however, has something better to give than treatment of disease, and that is prevention of disease. If children were brought into this world in the manner ordained by Nature and reared in harmony with the teachings of natural philosophy, disease would soon be a thing of the past. Human beings would then enjoy good health and be as beautiful and perfect in their kind as are animals, which live in the freedom of Nature, guided by instinct and therefore in harmony with the laws of their being.

We must begin, then, with prevention, for prevention is always easier and cheaper, than cure. But where must we begin to study the prevention of disease? Some will say, "At birth, because that is the beginning of life." Not so: that would be too late. The mould is made and the foundation laid for health or disease, for happiness or suffering, for efficiency or deficiency, before the human being in process of creation sees the light of day.

"Then," it may be said, "we must begin with prenatal influence, for the physical, mental, emotional and moral habits of the mother influence powerfully the development of the new life she is carrying." True—but we must start earlier than that. The making of the human being begins with mating and conception. All subsequent development depends upon the right start.

SECTION XXXII

Heredity

1. Importance of Correct Mating. Of primary importance in the sacred rite of procreation, as already intimated, is mating. This should take place only between descendants of the same subrace, or of closely related subraces such as the Indo-Caucasian and Celtic.

If the racial descent of the marriage partners is so far removed that it has produced pronounced differences in racial
characteristic—as in the case of the swarthy Mexican and white skinned Englishwoman, or the dark eyed Magyar and blue-eyed Scandinavian—then procreation becomes miscegenation and degenerates into mongrelization of the offspring. Everywhere in the animal and human kingdoms Nature has set the mark of disapproval on the mongrel. The offspring of miscegenation is doomed to deterioration and extinction unless assimilation of the elements of a lower race by a higher takes place sparingly and gradually.

The law of racial purity may be summed up as follows: When a member of a higher race cohabits with a descendant of a lower race, the offspring of the union loses more or less the characteristics of the higher race and reverts in physical, mental and moral traits to the level of the lower race.

The constructive results of racial purity are evident in Hindus of the higher castes; in that portion of the Jewish race which in mating has faithfully adhered to the Law of Moses, and in the blond and blue-eyed remnants of the Indo-Caucasian and Celtic races in Northern Europe and North America. The destructive results of miscegenation are plainly evident in the mongrelized population of Mexico and everywhere in the half-breed and many kinds of mixed breeds. These usually fall below the physical, mental and moral standards of the parent stock, and almost invariably revert to the customs and habits of the inferior race.

2. Use Heredity. Use heredity deals with the transmission to offspring of acquired physical, mental and moral characteristics of the parents. According to this law as it has been formulated, the chances of the offspring for long life, health, mental efficiency and moral stamina, other conditions being favorable, are better in direct ratio to the advancing age of the parents at the time of conception. While this is contrary to popular opinion, which assumes that younger parents produce more perfect offspring than older ones, the fact of use heredity is proved, both in the animal and human kingdom, by common observation and statistical evidence.

The working of the law is based on the fact that the procreative elements of the parents, or rather the microzyma of those elements, cannot contain the impress of physical, mental and psychical characteristics which at the time of procreation were not developed in the threefold organisms of father and mother.

The age of the father at conception is called the "birth age" of the offspring and determines its birth rank. While the father and previous male ancestors, for reasons hereafter explained, seem to exert greater control over the mental and physical characteristics, the mother furnishes the nutrient soil for physical growth. This does not mean that she exerts no control over the mental and psychical characteristics of the offspring; in addition to her influence through use heredity she has added opportunities through prenatal influence and postnatal training.
According to this law, then, the chances of the offspring for excellent physical, mental and moral development become better as the age of the father at the time of procreation advances beyond thirty five; while the physical condition of the mother for reproductive function is best below thirty five years.

But we must not overlook the fact that too great a discrepancy of age between the man and woman may become the cause of physical and mental incompatibility, of aversion and great unhappiness, especially on the part of the younger woman.

Extensive statistical evidence seems to prove that the birth age of the mother has been of less importance than that of the father. As will be shown in Natural Eugenics, the majority of famous men in all lines or human endeavor had old male ancestors, while the mothers and previous female ancestors were of much younger age at the time of conception.

This may be accounted for by the following reasons:

The man is usually considerably older than the woman at the time of marriage. Men, as a rule, devote much more time and effort to acquiring a scientific, professional or business education than do women. This has been true in the past more than it will be in the future. Thrown early into the competitive struggle of life men generally have had to make greater mental and physical effort than have women.

These points are of considerable importance because it has been proved that it is not inherited brain mass and mental capacity, but strenuous and persistent effort that intensifies use heredity. The earlier this begins and the longer it continues before procreation takes place, the better the chances of the offspring for physical, mental and moral capacity.

The reproductivity of the mother has usually ceased at thirty-five. Though she be capable of childbearing a few years longer, usually conception has been avoided after that age. Men under favorable conditions remain reproductive to advanced age. Some of the world's greatest men descended from fathers over sixty years old.

That intellectual and creative capacity has followed the male line of descent rather than the female line, is indicated by the fact that the high intellectual capacity of many eminent men has skipped their daughters to reappear in male descendants. This may be partly accounted for by the fact that the daughters in their limited spheres of activity have not had the opportunity to unfold inherent intellectual capacity to any conspicuous degree.

There has been a tendency in some quarters to criticize the general entrance of women into professional and commercial life and to dilate upon the adverse influence this will have
upon womanly characteristics and family life.

In the light of the knowledge we possess upon the subject of use heredity, it is safe to say that any such problematical drawbacks will be far outweighed by the general postponement of the marriage age. This will insure not only better physical fitness but also higher intellectual development and greater moral stamina on both sides of parentage.

The tremendous benefits which this increased hereditary endowment will confer upon future generations cannot be overestimated. Greater intellectual and economic equality between the sexes will emancipate woman from degrading sexual subservience. Under the old order, sex appeal was too often her only stock in trade by which to attract and hold the male and thus to secure a living. Economic independence will insure greater consideration and higher esteem for the woman on the part of the man. It will go a long way toward solving the problem of birth control in a natural way, by leaving it more largely to the judgment of the mother.

We find the law of use heredity according to birth age verified in the intelligence and moral development or obliquity of races, nations and tribes all over the earth—The lower the average birth age of a race or nation, the lower, other things being equal, the intellectual and moral development The greatest development and efficiency is found among those nations where marriage is delayed to a later age through custom, economic necessity, professional or military training.

The following quotation from "Control of Heredity", by Casper Lavater Redfield, is of interest in this connection:

"In general it may be said that wherever there are no restraints upon the sexual propensities, as with the Digger Indians, the Fuegians, the Andamanese, the Wauraus of the Guianas, the Bushmen and the tribes along the Gabbon river, there we find reproduction taking place at the earliest possible age, and the lowest grade of intelligence. Where we find some special circumstances or customs that delay the age at which reproduction takes place, as with the Patagonians, the North American Indian and the Polynesians, there we find considerably higher grade of intelligence.

"Where we find the custom of marrying late in life, as was customary with the Greeks and the Romans, there we find a very high grade of intelligence. And where we find a fortuitous succession of very late births, there we find the very great men of the world's history.

"In other words, the longer the time in which the individuals have in which to use, develop and strengthen their brains before reproduction begins, the greater and more powerful are the brains of their descendants."

In Volume IV of this Series I shall quote elaborate and
highly interesting statistics from Redfield, which reveal the effects of the various birth ages on physical, mental and moral characteristics. I shall confine myself, for the present, to the statement that, with few exceptions, the great artists, scientists, philosophers, statesmen and philanthropists were born from fathers whose ages ranged from forty to sixty-five years at the time of the procreation of their famous offspring.

The existence of these laws and principles as facts in nature is very evident in the training of racehorses and of other animals along certain lines of proficiency.

3. Pernicious Heredity. The effects of deteriorating and destructive heredity prenatal and congenital influences have been traced and commented upon in so many different ways that I do not believe it necessary to enter deeply into this phase of the subject. Various authors have filled entire volumes with the unsavory family histories of the descendants of the Jutes, Ishmaels and other drunkards, prostitutes, degenerates and criminals, which prove positively the transmission of morbid and pernicious traits through successive generations. It has been proved statistically beyond the shadow of a doubt that youthful delinquency, pauperism and criminality are the aftermath of immature marriages.

The laws of use heredity and prenatal influence, like all other natural laws and principles, manifest along opposite lines of expression. It remains for us to determine whether we shall align ourselves with their destructive or constructive activities. The effects upon ourselves and our offspring will show accordingly.

If I succeed in arousing the consciousness of prospective fathers and mothers to the glorious privileges and enormous responsibilities which these laws of nature confer upon them, then my labor will not have been in vain and I shall feel deeply gratified.

SECTION XXXIII

1. The Creative Alchemy of Love and Affection

Procreation—as is the case with everything else pertaining to the constituents and functions of the human entity—takes place on three planes of being, the material (physical and spiritual), the mental and the psychical planes. Which of these elements shall predominate in the offspring depends upon the mixture and adjustment of qualities in the triune makeup of the mating couple. In order to fulfill the law and to draw the divine blessing upon themselves and the fruit of their union the partners in the procreative function must be united by the bonds of love, or at least by the ties of true affection.
The source of creative genius is love and wisdom, and the essence of intelligence and power is sincerity and goodness. Without these, intelligence degenerates into selfish cunning, power into self-destructive brute force. The spring cannot rise higher than its source; its water cannot be pure and wholesome when contaminated by impure admixtures from filthy surroundings.

It is not generally known that use heredity pertains to intellectual and psychical qualities, as well as to the physical material. Animalism breeds nothing but selfish animalism. The vampire who craves and absorbs the love of its victims and robs them of vital energy, without being capable of feeling or bestowing affection, is the child of a discordant union—of brute animalism on the part of the man, of secret aversion and hatred, usually, on the part of the woman. These bestial and degrading tendencies on the one side, and unrequited love craving on the other, breed sex perversion, and propagate the harpies who delight in the seductive power of superficial beauty, while gloating over the weakness and ruin of their victims.

True love and affection, paired with intelligence and goodness; liberate the creative elements necessary to the production of perfect offspring.

The finer qualities of mind and soul open the fountains of life on the higher planes, liberate and harmonize the male and female procreative fluids, and charge them with the purest and most potent intellectual, spiritual and psychical elements.

The divine fire of creative genius burns only in the love aura of truly mated couples. It is true that these are rare under our artificial, unrighteous social institutions, and that accounts for the rarity of complete manhood and womanhood.

Perfect offspring, endowed with beauty and power of body, mind and soul, destined to shed through life a radiance of health, happiness and helpfulness—to love and be loved—issues only from the union of love and affection with intelligence and goodness.

"Love lieth at the foundation" (of all that is). "Love is passion, enthusiasm, affection, heat, fire, soul—God."

To the extent that love enters into the holy rite, to that extent its attributes will be absorbed in the threefold organism of the woman and become active in the child building in her womb. While she loves her man more than ever, her most passionate affection is centered in the new being in process of development. On it she bestows the purest and best in her food and drink, in her thoughts, emotions and secret desires. Fear, worry, anxiety, jealousy and hatred are strangers to her soul; these are the emanations of the lower spheres—she lives in heaven.

Somebody endowed with deep insight into these matters has
said:

"Whatever male and female shall truly will for, hopefully pray for and earnestly yearn for, when love pure and holy is the nuptive ascendant, in form, passional, affectional, divine and volitional, that prayer shall be granted, and the boon be given—but the prayer must precede."

What are the direct effects of the marital rite upon the participants? If the sex attraction operates on the physical material plane only, if lust instead of love presides at the matrimonial feast, then temporary gratification of erotic craving will be followed inevitably by monotony, satiety, gradual revulsion and aversion, culminating in a morbid craving for change and variety. The partners in carnal self-indulgence are intuitively aware of these tendencies to marital unfaithfulness, and, therefore, easily dominated by distrust and jealousy.

The procreative function is attended by complete satisfaction, buoyancy of body and mind and lasting happiness only when sex attraction operates on the higher and highest planes of being, as well as on the lower, when desire and impulse are operative on both sides. Thus only will the generative function fulfill its sacred purpose and confer the highest possible benefits upon parents and offspring.

The woman, being the more highly sensitized, must be responsive to the call of holy passion. To force unwilling compliance will ruin the woman, kill her love and curse her offspring. Balzac says: "He who begins with his wife by a rape is a lost man." It is impossible for a wife to love unless she is won, not forced to compliance.

2. Sexual Intercourse During Pregnancy. Sexual intercourse should be considered the most sacred function of the human entity. From the highest and best viewpoint it should be exercised only for the propagation of offspring. However, considering the present stage of ethical and moral development, temperate indulgence may not be wholly condemned. Excessive intercourse is always weakening and harmful to both participants. We must remember that the sex fluid is the carrier of the life force. It is that which constitutes strength, resistance to disease, initiative and genius. During abstinence from intercourse the sex fluids with their creative energy are absorbed through the inguinal glands into the organism and increase physical, mental, moral and spiritual capacity and energy.

Set rules for frequency of intercourse cannot be given. This must depend entirely upon individual conditions. One safe rule is that after indulgence there should be no feeling of satiety, weakness and exhaustion. The more frequent the indulgence the stronger will grow the power of habit and of passion and the greater will become the abnormal craving. It is the same with all other appetite and passions. The more frequently they are indulged, the stronger they grow, until
they attain complete control and develop into destructive habit

A free and confidential understanding in regard to these matters between those who contemplate matrimony would go far to prevent marital misery. A great deal of unhappiness arises from the fact that mates in the matrimonial union often labor under misapprehensions concerning the attitude of each toward the sex relation, and are prevented by excessive sensitiveness and delicacy from frankly discussing it. (For further discussion of this subject, see page 390, Volume I.)

There is no problem of married life that needs more thorough mutual consideration and understanding than this one. Lack of it accounts for a great deal of "incompatibility," loss of love, revulsion, hatred, and the final tragedy in the divorce court.

Among animals, no female allows intercourse after conception. In this respect as in many others, man has sunk below the natural standards of the animals. No greater crime can be committed against the woman and the unborn life.

It is a sad commentary on our system of education, scholastic as well as religious, that our young people are not instructed before and after marriage in these all important laws of Nature. To do this should be the province of the priest who unites them in marriage, or of the family physician, if the parents have failed in their duty.

It is well known (notwithstanding the denials of medical skeptics) that the unborn infant may be "marked" by transitory impressions, especially by strong emotions; that even insignificant parental characteristics are reproduced in the offspring. Is it any wonder, then, that the most powerful of human emotions should leave its impress on the growing brain and sex centers of the fetus, causing abnormal and precocious sex consciousness?

All too often is sex perversion born and bred in bone and flesh, before the child sees the light of day. The mother cannot be blamed for this "slaughter of the innocents"; she has not been instructed on the subject. Though she intuitively senses the horror of it, she submits, in order to maintain her hold upon the man—and many a life is thus cursed before it is born. The fault lies primarily with those of the medical profession who teach our young men that the free indulgence of sexual passion is not only legitimate, but a necessity to manly vigor.

This dictum of pseudo-science is almost universally concurred in by spiritual guardians. **No greater lie was ever promulgated from the blackest abyss of Hades.** If our young men were taught that greater happiness is to be attained by the exchange of tender affection than by the indulgence of the coarser animal appetites, that the creative forces thus preserved develop and strengthen their own finest capacities.
of body, mind or soul, they would wisely and chivalrously protect mother and child, at the same time conserving their own physical and moral integrity.

In no other way is it possible to call forth the deepest gratitude and unfailing esteem of a true woman. Many a man whom we have thus advised has become a lifelong friend in consequence.

3. Limitation of Offspring. I believe that the unlimited production of offspring, encouraged in some quarters for swelling the ranks of religious bodies or for increasing tax paying and cannon-fodder material, is a misfortune, both to the family and to society. Limitation of offspring, in accordance with the means and circumstances of the parents, is not only justified but should be encouraged. In any case, the production of offspring entails great responsibility upon the parents and if they cannot properly comply with the needs and rights of their children, they fail in their responsibility and duty.

Any method, however, which interrupts intercourse or prevents conception in an artificial way, is absolutely to be condemned, because this has very harmful and positively destructive effects upon the physical, nervous and mental organism of those who thus try to cheat nature by the suppression of a natural process. In our professional work we frequently meet the victims of such pernicious practices. The ordinary contrivances for prevention make of intercourse something akin to masturbation. This is also true of intercourse without orgasm which is strongly advocated under various guises. The use of poisonous antiseptics and germ killers in warm water douches is not essential for prevention, and is highly injurious. These chemicals have a tendency to poison the sexual organs and to produce in time atrophy, many kinds of female disorders, and tumors. Undoubtedly the greater number of so called female troubles and malignant tumors in later life are caused by curetments, antiseptic douches and the use of poisonous drugs, for producing abortion. The only legitimate methods of birth control are abstinence or common cleanliness.

There is nothing more conducive to the physical, mental and spiritual health and development of a woman than childbearing and child rearing in harmony with Nature's laws, as outlined in these volumes. Under favorable conditions it is not a thing to be dreaded, but to be looked upon as the greatest of blessings and opportunities in the life of a woman. Natural philosophy and practice takes these problems of progeneration, childbearing and childrearing out of the domain of uncertainty and haphazard management with its dire consequences, and makes eugenics the most exact of all sciences and the sublimest and most enjoyable of all the arts.

4. Determination of Sex. Numerous theories have been advanced concerning this interesting subject. Many attempts have been made to wrest from Nature the secret of sex
determination and numerous more or less ingenious methods have been recommended for sex control.

I know of one method only which seems to have a rational basis and which has proved of practical value. Observations seem to prove that the right ovary liberates male ova only, while the left ovary discharges female ova. The two ovaries discharge ova only at alternate menstruations.

With this data at hand, it is possible to determine the sex of a child after one birth has taken place. Suppose the first child was a boy. By consulting our pregnancy table (page 377) we can determine when the last menstrual discharge took place. This menstruation liberated a male ovum; the next menstruation would liberate a female ovum, the next a male, etc.

Thus, using the last menstruation period before the last conception as a fixed point, it would be possible, figuring from period to period, to determine the sex nature of the ovum to be discharged at each following menstrual period. Account is taken of all regular periods during the time menstruation is suspended in pregnancy. Thus, conception may be timed in such a way as to impregnate at will a male or female ovum.

This solves in a simple, rational manner another of Nature's riddles, namely, the reason for the practically equal division of the sexes.

SECTION XXXIV

Prenatal Influence

There exists just as much diversity of opinion among scientists concerning the reality of prenatal influence as about race heredity, use heredity, disease heredity and many other mooted problems of science and philosophy, which we shall study in Vol. IV of this series. In the following I shall present and examine impartially the various theories and opinions concerning prenatal influence; then we shall be better prepared to draw our own conclusions.

1. Medical Science Denies Prenatal Influence. Medical men, as usual cocksure of the correctness of their theories and hypotheses based on the "latest discoveries", deny and ridicule the possibility of prenatal influence, and relegate it to the rubbish heap of popular superstitions. They base their judgment on the fact that no nerves pass from the body of the mother through the umbilical cord into the growing fetus in the placenta, which forms the soft protecting nest of the new life within the womb. They claim that since no direct nerve connection exists between the two, mental and emotional vibrations cannot be transmitted from the brain of the mother to the brain and nervous organism of the fetus.
Are there no other means of communication between the mind of the mother and the brain of the unborn!

In the volume dealing with Eugenics we shall learn how universal intelligence and creative will become individual intelligence and personal will.

Cosmic vibrations do not flow into the gray matter of the human brain over coarse physical nerve tracts. They come over the psychical wireless which connects the human soul with the world Soul, the individual intelligence with the universal or cosmic intelligence the human will with the divine will.

Since, as proved by modern brain and nerve anatomy, immaterial cosmic intelligence and "power to will" fashion the brain of the mother into physical material centers for the expression of human intellectual faculties, capacities and powers, why cannot these cosmic vibrations act in like manner over the psychic wireless through the soul and mind of the mother on the brain and nervous system of the fetal organism?*

These epoch making discoveries and revelations of modern brain anatomy are explained in Vol. IV of this Series, Natural Eugenics—Man Building on the Physical, Mental and Moral Planes.

Why should the wireless, which transmits impulses of intuitive intelligence from the great source of all intelligence and creative energy into the soul of the mother, cease to operate at that point, and fail to transmit its message to the brain and nervous system of the fetus which is most intimately related and connected with the organism of the mother?

What about the phenomena of hypnotism? Absolute control of the subject's mind, through the intelligence and will of the hypnotist does not depend upon the existence of an umbilical cord and physical nerve connection between the two. The hypnotist, by silent command, may call his subject from a distance, far beyond the reach of his voice.

People telepathically attuned may communicate in like manner, spontaneously, or by conscious intent. Why then should we doubt the possibility of vibratory correspondence between the mental and emotional conditions of the mother and the plastic nervous organism in process of development within her womb?

If a complexity of sound can impress itself permanently upon the wax cylinder of a phonograph, or what is still more marvelous, if the photographic rays of passing scenes can be fixed and retained in the picture film, why should it be impossible for the mental and emotional vibrations of the mother to impress and modulate the molecular and cellular constituents of the fetal brain and nervous organism?
I have compared this creative power of the mother mind to the process of electrotyping. As the particles of metal in suspension in the fluid adhere to the spoon that is to be coated with silver, so the atoms and molecules in the gray matter of the brain of the fetus group themselves in harmony with the thought forms and emotional vibrations of the mind and soul of the mother. While this mental and psychical electrotyping takes place automatically, the mother’s brain and nerve molding power can be greatly strengthened and intensified by the conscious and voluntary operation of the psychical wireless that establishes vibratory oneness between her and the human entity in process of development within her own body.

Thus it is revealed how a brain prenatally refined, organized and fashioned may endow the nascent individuality with certain aptitudes and talents along established paths of cerebration. There surely will be less resistance along such lines of physical, mental and moral endeavor than along other lines not prenatally influenced and molded. Therefore I strongly advise mothers, pregnant with new life holding marvelous possibilities for good or evil, not to be influenced by the superficial reasoning of materialistic science, but to follow the sacred intuition and impulse of their own creative genius in this, the most holy function of their being. Every normally constituted mother is intuitively aware of this wonderful power, and is willing and anxious to exercise it when her consciousness has been aroused to the great possibilities and responsibilities which the divine privilege of motherhood confers upon her.

It is natural for us to admire a great artist who portrays the human form, true to life, on the painted canvas, or who fashions it from inanimate stone, metal or marble; how much more grand and godlike is the creative power of truly mated parents whose privilege it is to bring into the world, and to fashion according to their highest ideals, a human being endowed with life and intelligence, with the infinite possibilities of a new center of creative activity.

Yet many mothers, totally ignorant of their divine creative privileges and possibilities, victims of physically and morally degrading marriage relations, and often filled with secret aversion or open hatred for their marital companions, pass unwillingly through pregnancy and not infrequently seek to destroy the new life. When the unfortunate victim of such marital incompatibility, conceived in passion and developing under the worst possible influences of mental and emotional discord, comes to arouse the maternal instincts of affection and devotion, then fear, anxiety and worry, like a continual nightmare, haunt the unhappy mind of the mother and impress their discordant vibrations upon the sensitive films of infant consciousness.

Compare this condition of fear, apprehension and gloom in the mind and soul of an unhappy and unwilling mother, with the joyful and ecstatic state of mind of a mother conscious of
the creative power of her intelligent will, who, from the time of mating and procreation, with accurate prescience prepares the most favorable conditions, astrologically, prenatally and postnatally for the finest development of the physical, mental and moral characteristics of the future world citizen.

The loftiest exaltation of a creative genius working in dead clay and cold marble cannot approach the ecstasy of a mother who has acquired a knowledge of the great laws which make possible the development of a perfect human being, the embryo of a master, an angel, a being destined to be godlike in its faculties, capacities and powers!

In place of fear and anguish of soul, what joy to the mother who knows that it lies within her power to prevent disease and degeneracy in her offspring; that the development of the child depends solely upon her own intelligent effort! Nothing is left to accident. Child bearing becomes an exact science, the most beautiful and inspiring of all arts and professions. Under such conditions motherhood, instead of being the greatest of hazards and hardships, becomes a divine privilege and the highest achievement of human existence and endeavor. It falls short only of the creative work of the great Universal Intelligence whose instrument of creation is the mother.

2. An Example from History. Let us consider the oft-quoted example of Napoleon Bonaparte. His mother, Lutitia Bonaparte, while pregnant with the future military genius, accompanied her husband on a military expedition, sharing with him the hardships and excitement of camp life, and the marches and battles of a military campaign. If there be nothing in prenatal influence, is it not singular that Napoleon should have become one of the greatest military geniuses of all ages, while not one of his many brothers ever exhibited enough military ability to make an efficient corporal? What was it that favored or determined the birth of the great military prodigy under these circumstances? The ancestors of Napoleon's father were not professional soldiers, nor was the father especially interested in military matters before the conception of his gifted offspring.

The dominant influences, therefore, must have operated through the singular occupation and surroundings of the mother during this particular pregnancy.

Many similar striking examples have been cited in works on prenatal influence. I myself might add many convincing proofs from an extensive experience in medical practice; but time and space do not permit. Contributory evidence may be secured from many excellent works dealing with this vital problem in human life. I may be permitted to say that use heredity and prenatal influence are distinctly manifest in the physical and mental characteristics of our three children who were born at intervals of seven and five years. Each one of them clearly mirrors in his or her physical, mental and emotional peculiarities the predominant mental tendencies, occupation and surroundings of the parents during the
respective prenatal periods. Similar manifestations of prenatal influence may be observed in almost any family.

3. Birthmarks. Medical men of late deny also the possibility of "marking" the offspring by sudden fear or shock on the part of the mother during pregnancy. Incidents of this kind, however, are of such common occurrence that it is a waste of time to refute these flippant denials.

There are good reasons for believing that such marking is more likely to occur during the periods when the menstrual flow should take place, but is suspended.

It may be argued that to mention the possibility of marking to a pregnant woman will greatly increase the probability of electrotyping violent emotions upon her offspring; in other words, that the fear of the thing will help to materialize it. This may be true to a certain extent, but we must remember that sudden shock through fear or disgust may cause the mischief anyway, whether or not the expectant mother is aware of the possibility. Understanding a danger and being prepared for it seems the best protection. The pregnant woman should study carefully section XXX, dealing with mental and emotional causes of nervous diseases, and should learn to relax to any sudden surprise and thus neutralize unpleasant and fear arousing impressions. Self-control is the royal remedy and the key to mastership.

4. Physical Influence. Now that we have studied some of the more important hereditary mental and psychical prenatal and postnatal influences, let us see how the physical condition of the mother's organism influences the brain and nerve matter of the fetus in its last stages of development, and after birth.

Materialistic science teaches that brain matter exudes thoughts and feelings, as the liver excretes bile, or the stomach pepsin. Natural science proves that mind is superior to matter, that the new born ego, by the power of intelligent volition, must fashion in the gray matter of the brain the molecular groupings or centers for the expression of intellectual and emotional activities, such as language, music, numbers, scientific and philosophic speculation.

This means that active cerebration and brain molding do not begin until after birth. But it stands to reason that the work of the nascent intelligence may be greatly facilitated or impeded by the physical condition of the brain. It is reasonable to assume that intellectual and emotional vibrations will more easily shape the gray matter of the brain into new configurations when it has been prenatally refined, organized and developed along certain lines of cerebration by use heredity and by constructive prenatal influences.

There exists a remarkable similarity between the brain molding and memory building activities of the intelligent ego and the making of phonographic records and moving picture
films. Lifelike impressions of sounds and passing scenes can be made upon the phonographic and photographic mediums only when wax and film are in a highly refined and plastic condition. When impure of substance and coarse of texture they, are not sensitive and plastic enough to register and retain the subtle and highly complex vibrations of sounds and passing scenes. In order to receive and register a great variety and complexity of sounds, the wax on the phonograph cylinder must possess a certain degree of refinement, softness and plasticity. If it is too hard and coarse it registers the loud and coarse sounds only. Such a record cylinder, exposed to a beautiful symphony executed by a great orchestra, would register and reproduce only the shrill cries of the trumpet, the rattle of the snare drum and the booming of the big horns and bass drums. The softer sounds of string, wood and wind instruments and finer shadings of tone and rhythm would be lost. With increasing refinement and plasticity, more subtle and delicate sound vibrations will be retained and reproduced.

In like manner the sensitive gray matter of the cortex of the brain must be in a pure and plastic condition in order to receive and register the impressions and impulses coming through the sensory organs, the psychic intuition and the intellectual and emotional activities of the mind. Anything in the way of physical impurity or foreign matter that tends to clog the brain, or to feed it with waste and morbid materials, or with corroding poisons, will lessen the atomic and molecular motility of brain and nerve matter, and will interfere with, or impede, the groupings and subtle transformations involved in the fashioning of brain centers through mental and emotional influences.

If the nutrient blood which feeds the brain substance of the fetus be saturated with CO₂, the benumbing, paralyzing carbon-dioxide, with clogging uric acid or the destructive acids of phosphorus and sulfur, the gray matter cannot, respond to the subtle and complex impressions and impulses from without and within.

The purity or impurity of the plastic matrix of the cortex depends upon the materials absorbed from food and drink. If these are so constituted as to create in the system excessive amounts of clogging and corroding substances, then these food and drink poisons will have a benumbing and deteriorating effect upon the sensitive gray matter of the brain, as well as upon the coarser tissues in the joints, muscles and vital organs. There is a rheumatism of the mind as well as of the joints.

A brain asphyxiated and clogged with pathogenic materials cannot be alert and active; it is too dull and lazy to think; it would much rather sleep than work; it is incapable of doing its best when its tiny blood and lymph vessels are obstructed with waste and morbid deposits which prevent the oxygenation and drainage of its delicately organized cellular tissues.
This, of course, is true postnatally as well as prenatally. A brain originally capable of the highest and finest achievements of the human mind may become utterly worthless, and may degenerate into idiocy through food, drink and drug poisoning.

Medical men tell mothers they need not worry over prenatal feeding, because the placenta, the vascular bag which forms the nest of the new life, acts as a filter which purifies the blood before it reaches the fetus. Common sense and every day experience tell another story. Even the best in the blood of many mothers is bad enough to serve as food for the new life.

The placenta does not filter out of the blood of the mother all food, disease and drug poisons. This is proved by the wretched condition of many infants, suffering from malnutrition, anemia and rachitis, after delivery. If the vital fluids of the mother are deficient in the mineral elements, or in other important nutritive substances, how can they deliver them to the fetus?

Occurrences like the following, quite common in our institutional practice, prove positively that the placenta is not a perfect filter for systemic poisons and for disease taints circulating in the blood of the mother.

One of the most pitiable cases of eczema in a little child less than one year old we traced to the fact that the mother, during her first year of marriage, had traveled with her husband through Eastern European and Asiatic countries, and during her pregnancy had been vaccinated five times while passing through localities where smallpox was prevalent. Both she and her husband had always enjoyed perfect health. The family record was excellent as far as traceable; still the body of the infant soon after birth, was covered with open bleeding sores, presenting a revolting sight. We could find no explanation for this strange phenomenon other than the many vaccinations during pregnancy. These had contaminated the blood of the mother, and through her the body of the fetus, with a filthy scrofulous taint.

The baby suffered terribly. For many months it slept but little, because of the excruciating pains. The eczematous eruptions were of a very stubborn nature; they broke forth again and again. Finally, however, after eighteen months of natural treatment, we succeeded in purifying the little body of the horrible infection. The child is now a little over three years old, in perfect health, and during the last twelve months has shown no signs of the morbid taint.

Under another section I shall describe the influence of food upon character and sex life.

To recapitulate: Purity, plasticity and motility of the highly refined and sensitive materials which make up the gray matter of the brain depend upon pure food, plenty of fresh air and exercise, and upon all other natural methods of living.
SECTION XXXV

Conception and Pregnancy

1. Conception takes place whenever the male spermatozoon joins the female ovum (egg) within the woman's womb. Normally the female organism liberates from its ovaries but one ovum each month, usually during menstruation, while the male discharges millions of spermatozoa at each orgasm.

Conception does not always follow copulation. The ovum remains in the womb and is capable of impregnation for about five days after menstruation. The spermatozoon on entering the womb may meet an ovum which has been discharged at a previous menstruation, or it may remain alive in the womb for a number of days and finally come in contact with a newly discharged ovum at the following menstruation.

The spermatozoon retains its ability to impregnate the ovum for from ten to fifteen days after its discharge into the womb. When the male and female germs merge into one another, conception or impregnation takes place. As soon as this has happened, the impregnated ovum becomes attached to the inner lining or mucous membrane of the womb and begins its new life as an embryo. The period comprising the time from the impregnation of the ovum until the beginning of labor or childbirth is called pregnancy.

The table of pregnancy on page 377 indicates the probable date of normal termination of a pregnancy, calculated from the last menstruation.

2. Exercise During Pregnancy. Unfortunately a great many expectant mothers labor under the idea that they must rest and be relieved from work and exercise. This of course is a great mistake. Light housework is good exercise. There is nothing more harmful during pregnancy than nursing "that tired feeling" by lounging idly about the house and coddling one's real or imaginary aches and troubles.

Of great benefit to the pregnant woman are all outdoor sports such as tennis, golf and other games which require vigorous exercise without straining or overworking the body. The great benefit of walking and other outdoor exercises, aside from their general invigorating effects, lies in the strengthening of the abdominal muscles and ligaments, which at delivery will greatly facilitate expulsion of the fetus.

The walk should be brisk and rhythmical, body erect, head thrown back, chest forward; the breathing at the same time should be deep and regular. These walks should be continued as long as time and endurance permit. Nothing, of course,
must be pushed to the point of exhaustion. One good long walk every day is necessary; two are better.

We all understand the necessity for a plentiful supply of oxygen under ordinary conditions, and especially in time of illness. During pregnancy the demand for oxygen, as well as for mineral salts, is doubled or trebled on account of the needs of the rapidly developing organism in the womb of the mother.

These extra demands for oxygen and ozone must be supplied by systematic deep breathing, cold bathing, outdoor walks, etc. If circumstances do not permit the taking of outdoor exercise, deep breathing should be practiced as often as feasible, at the open window.

Next in importance among gymnastic exercises is the internal massage described under section XXI, No.16.

Those exercises are especially valuable which bring into play the abdominal muscles and the muscles and ligaments of the genital organs.

3. Clothing. Clothing and the manner of wearing it profoundly influences the normal or abnormal development of the fetus, the health of the mother, labor and delivery.

At no time should the waistline be constricted by a corset or even by the ordinary skirt band. All clothing should be as loose and light as possible—one-piece under and outer garments, with the weight suspended from the shoulders, are best. If skirts are worn they should be fastened to skeleton waists of some thin cotton material. The close, heavy texture of the material from which the corset or so called "reform waist" is made is injurious because it interferes with skin elimination.

Even the slightest constriction of the waist line interferes with the free circulation and the normal blood supply to the abdominal organs, which is of especial importance in pregnancy; it also hinders the free expansion and movement of the uterus during the various stages of pregnancy.

Within the waistline are located a dozen or more important vital organs of the body. Any sort of constriction compresses these organs and pushes them out of their normal position. While this is extremely injurious to the body of a woman under ordinary conditions, it is doubly so to the pregnant mother and to the rapidly growing fetus. Undoubtedly many deformities and monstrosities are produced by unnatural constriction of the blood vessels and vital organs in the abdomen and pelvis of the pregnant woman.

If due attention is paid to the foregoing influences, labor and delivery will be brief and easy. This we have proved in hundreds of cases which have come under our management. The reason why women of civilized countries spend many
hours and sometimes days in dreadful agony of childbirth while those of primitive or savage races, as we call them, produce their young easily and painlessly as the animals do, is that primitive women live more simple and natural lives, while "civilized" mothers violate practically every law of Nature in their daily habits of living.

Civilization unfortunately stands in many respects for that which is artificial, unnatural and therefore productive of disease and suffering in all domains of life, not only as regards physical health, but social and political health as well.

SECTION XXXVI
Danger Signs During Pregnancy

1. Dropsical Swelling. Swelling of the limbs and distention of the veins of the legs during pregnancy may be caused by a tendency towards varicosity, intensified by obstruction of the circulation due to the enlarged uterus. Such a condition requires, aside from the natural regimen, careful and competent treatment.

Swelling of the limbs or other parts of the body may also be caused by incipient or advanced Bright's disease. The urine should be examined from time to time, especially if there is a swelling of the feet and ankles, or if there are dropsical symptoms in other parts of the body.

Such dangerous conditions are usually brought about through the excessive intake of starchy and protein foods which overwork the liver and kidneys and cause pathogenic dogging of the capillary circulation. This may result in uremia attended by violent and sometimes fatal Convulsions.

2. Uremia is the result of retention in the system of waste materials and poisons that should be eliminated through the kidneys and skin. Medical treatment for such conditions, aside from the administration of stimulating drags, consists in hot bathing with the idea of opening the pores of the skin.

We understand that all hot water treatment gives only temporary relief and is followed by greater enervation and inactivity of the skin. The best water treatment for systemic poisoning of any kind consists in the application of wet packs followed by cold ablutions as described in section XV.

The addition to the packs, dry friction rubs, air bath, good massage and neurotherapy treatment will aid in restoring the normal activity of skin, bowels and kidneys.

Whenever the urine contains sugar or albumen, fasting, alternating with raw food diet, is indicated. Suitable regimens are outlined in sections X, XI.
The giving of heavy food to the mother with the idea of increasing the flow of milk is all-wrong. We have found in all cases that the diet outlined in section X will produce a more copious flow of rich milk than lie "nourishing" meat diet. The best remedy for a scanty flow of milk is slow and thorough mastication of a few spoonfuls of raw crushed wheat every day.

3. Morning Sickness. One of the common disorders experienced during pregnancy is that known as Morning Sickness. One suffering from this ailment, though following a natural diet, should sip a cup of hot postum while remaining in bed. If this does not have the desired effect and if the patient has not been accustomed to drinking coffee, half a cup of black coffee with a few drops of lemon juice will quiet the irritated nerves. It is necessary after taking the hot drink to remain in bed for at least thirty minutes. It is understood that this is only an emergency measure. If continued, it will lose its good effect and work injury.

SECTION XXXVII

Labor and Delivery

At about forty weeks, exactly nine solar months, from the period of conception the fetus reaches full maturity, and labor begins. Labor is divided into three stages. During the first stage the neck of the womb becomes slowly and gradually distended and the orifice of the womb opens widely. When this has taken place, the fetal membranes burst and the amniotic liquid surrounding the fetus escapes.

During the second stage the fetus emerges from the womb.

After expulsion of the fetus, the placenta is expelled from the uterine cavity. This constitutes the third stage of labor.

The first stage usually begins with more or less radiating pains in the abdomen, accompanied by dull pain in the small of the back and a drawing pain in the limbs. Sometimes women with the first baby feel these pains weeks in advance of the actual commencement of labor. At first they occur at long intervals and are of short duration, but gradually become more prolonged and more frequent. The pains are due to a cramp-like contraction of the muscular apparatus of the uterus forcing its contents downward.

Under this pressure from above, the neck and mouth of the uterus distend to their limits, and the walls become thinner and thinner. First the inner, then the outer orifice of the neck of the womb opens and the fetal membranes protrude and finally rupture, allowing the amniotic fluid to escape. Shortly after this the part of the fetus nearest the orifice, normally the
head, makes its appearance. At the present time the average
duration of the first stage of labor is six hours, but it may last
twenty-four hours or longer, depending upon the plasticity
and elasticity of the bony structures of mother and infant, the
rigidity of the cervix, and the vigor or lack of vigor of the
muscular apparatus of the uterus.

While the foregoing is true of the average delivery under
ordinary ways of living, we find that after the enforcement of
a natural regimen of living during and, better still, before
pregnancy, the entire period of labor and delivery does not
cover more than half an hour, or at the utmost from one to
two hours. Even the disadvantages of slight build and
smallness of pelvis can be overcome by the natural regimen
outlined in section X. When our youngest child was born, the
mother gave the first sign of pain at about midnight. I rose
from bed instantly, but had not time to finish clothing when
the membranes broke. Within twenty minutes after the
commencement of labor the infant was resting in my hands.

The wife of a prominent lawyer in a western city had
experienced three difficult deliveries. Each time surgical
instruments had to be used and she had suffered untold
agonies lasting from 24 to 36 hours. When she became
pregnant the fourth time the most prominent physicians in her
home city assured husband and wife that it was not safe for
her to go through another delivery, that the womb was in
worse condition than ever before therefore they recommended
surgical removal. For conscientious reasons, however, the
husband and wife did not follow the advice of the doctors, but
decided to try natural methods of treatment.

The lady placed herself under our care during the fifth
month of pregnancy. From that time on she followed strictly
the natural regimen of living and received daily the usual
hydropathic and manipulative treatments. This was continued
until a few weeks before delivery. In this case the baby was
born within an hour from the first contraction, and the mother
of the patient, who was in an adjoining room, had not heard a
sound. Many similar experiences refute the idea that it is
unsafe and injurious for pregnant women to undergo the
ordinary methods of natural treatment, such as hydropathic
sprays, sitz baths, massage, Swedish movement and other
forms of manipulation.

1. Preparation for Delivery. The diet during the last week
before the beginning of labor should be very light, consisting
mostly of fruits and vegetables. From the commencement of
labor no food at all should be given, until at least twenty-four
hours after delivery; a three-day fast is better.

In addition to a competent physician, a nurse or midwife
should be engaged. If a good neurotherapist, who has had
sufficient experience in obstetrical work, can be procured, he
should be preferred, because he can assist delivery and make
it much easier by manipulative treatment.
The nurse will make the necessary preparations and provide the various supplies needed in labor. With the first sign of approaching labor, the physician in charge should be summoned. A rectal enema of one pint or more of warm salt water (See. XVIII, No.4) should be administered. The woman should be given a vigorous cold rub and her genitals thoroughly cleansed. She may then remain on her feet and walk about, comfortably dressed, until actual labor commences.

2. No Anesthetics. The attending physician should not be impatient to hasten delivery with drugs or instruments. The use of anesthetics should be avoided insofar as this is possible. They should be employed only when absolutely necessary—that is, when excessive pain must be allayed or when surgical delivery is unavoidable.

3. Breaking of Water Bag. When the bag of water is about ready to break, the patient is placed in bed. Premature discharge of the amniotic fluid must be guarded against. An escape of the liquid at an early stage means difficult and prolonged labor, commonly known as "dry labor". Usually the membranes burst when the orifice is fully dilated. A large sponge is held in readiness to catch the out-flowing liquid.

3 a. Umbilical Cord. When the infant has been delivered, the umbilical cord should not be severed at once. Plenty of time should be allowed for the blood to transfuse itself from the body of the mother to that of the child. This is important. If the connection is severed too soon, the child begins life in an anemic condition.

The newborn baby usually greets the world with a lusty cry. It should be placed on its right side with its face turned away from the mother, care being taken that the cord is not stretched tight. As soon as the cord stops pulsating, plenty of time being allowed for blood transfusion, it is tied about two inches away from the baby's abdomen and cut a little above the ligature. The baby is now wrapped in a warm blanket and put in its crib.

4. After Delivery. Immediately after the baby is born, the nurse or attending physician gently compresses the abdomen and womb of the mother, kneading and rubbing it occasionally in order to secure complete contraction and thus prevent hemorrhage. After delivery the mother enjoys a period of rest and recuperation which usually lasts for about half an hour.

5. Afterbirth. Meanwhile the placenta becomes detached, and when the pains set in again a few contractions usually suffice to expel it with all the membranes.

The attending physician must make sure that none of it is left in the body, since this might result in putrefaction of the remains and blood poisoning. The woman's genitals should be washed with clean sterilized water.
The exhausted woman should now enjoy a deep, wholesome sleep and awaken from it in a few hours refreshed and strengthened.

In the foregoing I have not gone into the details of obstetrics and of technical management because this must be left to a competent obstetrician. I have called attention only to those points which are of special importance from the viewpoint of Natural Therapeutics and to the differences in treatment between the conventional and natural methods.

6. The Lying-In Period. The lying-in period varies from five to twelve days, according to the constitution of the mother and the care that she has taken during pregnancy. The greatest danger of the lying-in period is puerperal sepsis or blood poisoning. This condition is the result of infection occurring during labor, or it may result from the retention of parts of the placenta.

The only way to prevent this is by observing the most scrupulous cleanliness during the entire process of childbirth and during the lying-in period. When blood poisoning has developed it must be treated the same as all other acute inflammatory diseases (see section IX).

7. Care of the Newborn. The child should begin to breathe immediately after the cord is cut. If it fails to do this, the physician should lift the baby by its feet to facilitate the escape of mucous from the trachea and throat. If necessary the mucous must be removed from the throat by the insertion of the little finger, or by means of a tiny stick covered with gauze.

Breathing may be accelerated effectively by a few sharp taps on shoulders and buttocks. If this fails to bring the desired result, artificial respiration must be resorted to at once. The attendant grasps the child by its shoulders, its head resting between his palms and the two index fingers being hooked under the child's armpits. It is now swung between the physician's legs and lifted high above his head so as to be turned upside down. This is repeated from fifteen to twenty times, after which it is placed in a basin containing a few inches of warm water. Its body should then be rubbed briskly with cold water.

Father Kneipp used to take the newborn babe by the nape of the neck and the feet and submerge it quickly in cold water. This, a few times repeated, is probably the quickest way of resuscitating an asphyxiated baby.

In order to soften the cheesy deposit which frequently covers the body of the newborn, it is well to rub the skin with warm olive oil. After the greasy covering has sufficiently softened it may be removed with bits of gauze. This is followed by a cleansing bath with warm water and castile soap.
After the warm cleansing bath, the little body should be quickly rubbed down with cold water, wrapped in a soft, warm blanket and laid away to sleep until it awakens of its own accord. A normal baby should sleep for about twelve hours, and must not be disturbed to force food on it before it is ready to take it.

8. Bathing. From the first day, the baby must have a morning and evening bath. This consists, as before described, in a quick, cleansing bath of warm water and castile soap, followed immediately by a brisk cold rub. In the course of a few weeks the baby can be placed, for the cleansing bath, in a small bathtub containing a few inches of warm water. Immediately after the cleansing bath the warm water is replaced by cold water. This is taken up in the hollow of the hand and briskly applied to the little body. In this fashion the child, within a few months time, will enjoy its cold rub just as much as an adult. I have seen several such nature cure babies, but a few months old, object most vigorously to a warm bath. The cold rub is the best preventive of chilling; but care must be taken that the temperature of the room where the bath is given is not below 70 deg.

The olive oil bath or rub, often recommended for premature babies or infants suffering from malnutrition, is very injurious, because it occludes the pores of the skin and prevents the elimination of poisonous gases and other morbid materials from the body. The skin is not an organ of digestion. Olive oil, like all other foods, must enter the body through the alimentary canal where, under the action of digestive ferments, it is broken down into its component elements which are then assimilated through the intestinal membranes. Oil absorbed through the skin is not digested, and it circulates in the body as foreign matter which in this state cannot be assimilated and utilized in the system.

9. Powdering after the bath is fully as injurious as the rubbing with oils or massage creams. Powders and creams tend to clog the pores, and most of them contain poisonous antiseptics which lower the vitality of the skin and prevent or suppress elimination in the form of skin eruptions, eczemas, etc. For chafing use nothing but cold water. In case the chafing should become unusually severe and painful, through neglect by the caretaker, a soothing and healing lotion composed of one part lemon juice to two parts olive oil, may be applied a few times, until the irritation is under control.

10. Air Baths. Next to cold water, there is nothing that will invigorate baby's skin and nervous system as will the air and sun bath. If the season will not allow the outdoor air bath, the baby should be allowed to lie nude several times a day, for thirty minutes or more, in a warm, well ventilated and sunny room.

11. Constipation. Glycerin and suppositories should never be used; neither laxatives nor cathartics. Oat extract and cooling sitz baths will produce natural movements.
12. **Diarrhea** is a form of morbid elimination, and must never be suppressed by drugs. If it is habitual, bailey or wheat extract prepared in the same manner as oat extract, is a good remedy. If the diarrhea is persistent and of a violent nature, no food at all must be given, except water with dilute acid fruit juices, until the purging ceases. Even then plenty of time must be allowed for the rebuilding of the sloughed intestinal membranes.

13. **Bandages.** Until the umbilical cord dries up and falls off, it is necessary to cover the navel with a gauze compress dipped in olive oil. This is held in place by an abdominal bandage made of soft cotton material. These strips should not be hemmed, merely torn or cut. They should be drawn just snugly enough to hold the compress in place, but not tightly enough to interfere with circulation. The, navel must be cleansed and the compress renewed twice each day. After the umbilical cord has dropped off we no longer apply the abdominal bandage. This is contrary to common usage, but is the best practice. The abdominal bandage overheats the body and interferes with the free movement of the diaphragm and the circulation of the blood.

14. **Clothing.** The clothing of the infant should be loose and light and as simple as possible. Freedom of movement is very important; binding or pressure upon any part cannot help but interfere with the circulation, and otherwise produce injurious results. The clothes should be short, in order to allow the feet and legs free play. Light weight, porous cotton materials are best for both under and outer garments. A lightweight wool petticoat may be worn when absolutely necessary to provide sufficient protection for the baby. Cotton hose and bootees may be used, but under no circumstances should such articles be of wool, because it prevents free elimination from the skin. The baby's head should not be covered out of doors, except in severe weather. At no time should a veil be placed over the face, as it will cause the infant to reabsorb the poisonous exhalations from its own lungs. All clothing should be changed each day. No garment should be starched—such a practice is not only useless but harmful.

15. **Diapers** must be provided in sufficient number to allow thorough cleansing and drying. The wet diapers should be scalded in hot water and very thoroughly rinsed in several waters afterwards. They should then be dried in the open air and sunshine. Soiled diapers must be well washed and boiled. Washing powders, soda, ammonia and other chemicals should never be used. They have an extremely irritating effect upon the delicate skin of a baby. In order to save labor and to facilitate the cleansing of the diapers, small squares of clean old linen or muslin rags, or pieces of absorbent gauze, may be placed inside. These inserts will absorb all or most of the bowel movement and may then be burned. If the skin is irritated or chafed, the parts should be sponged off with clean cold water at each change, paying special attention to cleansing of the genitals. Oils or powders must not be used to soothe the sore places, because they clog the pores and
Interfere with natural elimination.

16. A wet nurse is to be preferred to artificial feeding. She should be thoroughly healthy, not over thirty years of age, of equitable temper, not excitable or nervous and her diet should be that prescribed for the mother.

17. Care of the Nipples. They should be thoroughly cleansed before and after nursing; not with carbolic acid, but with water and dilute lemon juice. The lemon juice tends also to harden the nipples. Treatment of the nipples may begin before the birth of the child.

18. Care of the Eyes. The baby's eyes, whether awake or asleep, should always be shielded from strong light, either sun or artificial, and from dust and wind. The eyes should be washed with cold water after every cleansing bath. If they show any tendency to weakness or disease, slight vibratory massage over the closed eyelids should be given after the cold eye bath.

19. Care of the Mouth. A healthy baby's mouth needs no cleaning before the arrival of teeth. As a matter of fact, the teeth of a perfectly healthy adult would not need cleaning any more than do those of an animal living in the freedom of nature. The saliva is a sterilizing fluid, under normal living, intended by Nature to keep the mouth clean and healthy. Cleansing of the mouth of an infant with the finger or with a cloth may injure its delicate membranes. If the mouth must be washed, in case of disease, a swab made by twisting a piece of sterilized absorbent cotton on the end of a smooth stick should be used. The swab should be dipped in warm boiled water, and the interior of the mouth washed thoroughly, the cotton then being burned.

20. Care of the Ears. The external ear should be cleansed with a soft rag or swab as before described. Never use a hard instrument inside the ear.

21. Care of the Nose. A baby's nose should be cleansed as a part of the daily toilet, in the same way as the ears. A swab may be made by twisting a, piece of gauze to a cone. As soon as the child becomes old enough, it should be taught to sniff up cold water through the nostrils and the nasal passages. This is the best way to keep the nasal membranes in a clean, healthy condition.

22. Care of the Genital Organs. The genital organs of both sexes must be kept scrupulously clean with as little handling as possible. The foreskin of the penis of the male baby should be drawn back at bathing time and the organ thoroughly cleansed, always finishing with cold water.

23. Phimosis. The treatment of phimosis is fully described under Sec. XXVIII, No.1.

24. How to Lift the Baby. The best way to lift a young
baby is to slip the left hand under the back beneath the shoulder, spreading out the fingers in such a way as to support the neck and head. Then lift the feet and legs with the right hand. Never lift an infant without first supporting the spine.

When a baby has grown strong enough to hold up its head and has gained considerable strength in the muscles of the back and neck, he may be lifted by grasping him with outspread fingers under the armpits; the body must be held firmly so that the entire strain does not come on the shoulders. A baby should never be lifted by the arms. This may dislocate the shoulder joints.

SECTION XXXVIII

Prenatal Feeding

1. Effects of Diet During Pregnancy. The problem of infant nutrition begins before birth. Prenatal feeding determines the physical start in life. On it depends not only the condition of the mother's health during pregnancy, but also the size and weight of the fetus, pliability of the bony structures, ease or difficulty of delivery, and the quality of the mother's milk.

The fleshier and heavier the newborn infant, the prouder and happier are the parents and the doctor Yet, excessive size and weight of the child constitute the most prominent cause of difficult and painful childbirth and frequent necessity for instrumental delivery.

The biblical saying, "In sorrow thou shalt bring forth children"; has led many to believe that woman's dreadful suffering is a necessity, God ordained; but is not man's ignorance, rather than the cruelty of an avenging God, to blame?

This latter view is confirmed by the fact that other mammalia literally cast their young, without pain or difficulty; and the labor pains of primitive mothers are insignificant, their delivery presenting little more difficulty than that of the lower animals. A squaw on the Western Plains stops a few hours by the wayside to deliver her papoose and then resumes her journey as though nothing had happened.

Women among the European peasantry, who wear no corsets, live on black bread and vegetables, and have plenty of exercise in the fields and in the home to the last day of pregnancy, have their babies without help of midwife or physician and resume their usual routine of work within a few days after delivery.

Thousands of mothers who have adopted natural ways of
living have learned to dispense with anesthetics and the
surgeon's instruments; they now bring forth their offspring
without excessive pain.

2. Results of Faulty Diet. It is significant that the offspring
of the lower animals, at birth, consist of little more than skin
and bones, while the newborn human is often abnormally
large and fat. This is especially true of babies born of weak
and anemic mothers. As before stated, excessive size and
weight of the infant is not a matter for congratulation, but is a
pathological condition. It indicates fatty degeneration of the
fetus, due to the anemic watery condition of the blood of the
mother, and the cause of this hydremia of mother and child
lies in the faulty dietetic habits of the former.

The ordinary diet of American women consists almost
entirely of meat, fish, fowl, potatoes, white bread, pastry,
coffee, tea and refined white sugar. The few vegetable, which
enter into the daily dietary are first deprived of their all
important organic salts by faulty cooking; fruits are looked
upon as luxuries and frequently are regarded as harmful

The anemic, watery condition of the blood of mother and
child is not due to a lack of starchy, protein and fatty materials
in food and blood, but to a deficiency of organic mineral
elements. Neither is the anemic condition, as the regular
school of medicine assumes, caused by lack of iron. Any
ordinary food mixture, as well as the blood and milk of
anemic mothers, usually contains a sufficient amount of iron.
The actual cause of the anemia is a deficiency of other
mineral elements.

As I have explained in Volume III of this Series, carbonic
acid poisoning and the resulting sluggishness of the surface
circulation, coldness of the extremities and congestion of the
inner organs is not caused so much by a lack of the oxygen-
carrying iron as by a deficiency of the carbonic acid
neutralizing and eliminating sodium and magnesium.

If the blood is deficient in lime, phosphates, silicon and
fluorine, rachitic conditions, softening of the bones, deformed
spines and legs, and decay of the teeth, are inevitable results.

It is an easy matter to supply the daily needs of the
organism for proteids, starches, fats and sugars; the difficulty
lies in supplying a sufficient amount of the organic mineral
elements.

The deficiency of sodium in human blood, Dr. Lahmann
proved in the following table of comparative blood analyses.
In a hundred parts of ash he found in the

<table>

</table>
The percentages of lime and of other positive mineral elements in the human blood are also much lower than in the blood of cows, oxen and sheep.

While the blood of cattle and sheep raised on pasture is very uniform in composition, hardly any two samples of human blood are alike. It is for this reason that Dr. Lahmann adopted cow's milk instead of human milk as the standard elementary food combination.

In the following table, he compares the percentages of minerals in the ash of cow's milk with the percentages of mineral elements in the ash of various other food materials.

A daily dietary consisting largely of meats, eggs, white bread, potatoes, peas and beans, though excessively rich in proteids, fats and starches, will, on account of its deficiency in sodium, lime and magnesium, inevitably result in carbonic acid poisoning, anemia, rachitis, premature decay of the teeth and a multitude of other acute and chronic ailments.

If, however, the daily dietary contains a liberal amount of green vegetables and fruits, a normal food mixture resembling that of cow's milk can easily be obtained. It must be remembered that fruits and vegetables are not only rich in the most important mineral salts, but that they are relatively poor in proteids and carbohydrates.

For this reason fruits and vegetables facilitate the establishment of an equilibrium between proteids and carbohydrates on the one hand and organic mineral salts on the other.

3. Excessive Fat Formation. We can now understand why the ordinary faulty diet of pregnant mothers causes anemia, softening of the bones, sluggish circulation, carbonic acid poisoning and fatty degeneration in mother and offspring.

Lack of sodium causes excessive accumulation of carbonic acid, and oxygen starvation. This results in defective...
oxidation of food and waste materials; in other words, in fat formation.

Defective draft prevents the complete consumption of coal, and chokes the furnace with the products of imperfect combustion. Similarly, lack of oxygen in the tissues (due to carbonic acid poisoning) causes an incomplete combustion of food materials and waste products, resulting in fat formation and in the generation of poisonous byproducts.

Lack of sodium also prevents the neutralization and elimination of uric and other acids and ptomaines (pathogenic matter) which accumulate in the tissues, block the circulation and assist in the smothering of the vital processes.

In order to eliminate these pathogenic materials, there arises an abnormal craving for water—"the anemic thirst"—which is closely related to the thirst of fever patients and of diabetics. Excessive water drinking is encouraged by the popular "flushing" fad.

To make things worse, the anemic, for reasons before stated, usually suffers from weak heart action and sluggish circulation. This means defective elimination of water through the skin and kidneys, resulting in a watery (dropsical) condition of the tissues and fatty degeneration.

Not all anemic, carbonic-acid-poisoned mothers, however, develop a tendency to obesity. On the contrary, under certain constitutional conditions, they may become exceedingly lean, like the anemic, carbonic-acid-poisoned consumptive. Briefly stated, sluggish heart action and weak kidneys favor retention of carbonic acid and water in the tissues and thus make for fatty degeneration. Good circulation and normal activity of the kidneys may keep the system free from excess of water and carbonic acid, but excessive proteids in the diet may result in sulfuric and phosphoric acid poisoning. These destructive acids break down the tissues, rob them of their mineral constituents, and thus cause excessive loss of flesh and fat.

In both types of dysemia the blood of the pregnant mother is overloaded with poisonous gases, waste matter and the debris of broken-down tissues. The oxygen supply to the fetus is therefore very much impeded and we find that both fleshy and lean mothers produce babies of abnormal size and weight, ranging from eight to twelve pounds, while **the normal weight of the newborn should not be more than six pounds.**

4. **Advantages of Natural Regimen.** We know of many instances where mothers, after having given birth to heavy, fleshy babies, in subsequent births have reduced the weight of the new born to normal, and the pain of delivery to a minimum, by the adoption of a natural diet, plenty of exercise in the fresh air and systematic deep breathing.
The effects of a natural regimen are manifested in various other ways. The bony and muscular structures of mother and child are much more pliable and elastic, making parturition and delivery much easier. Pure blood, normal nutrition and abdominal exercises, walking and special gymnastics, greatly strengthen the abdominal and uterine muscles, thus facilitating expulsion of the fetus.

The morning cold rub, systematic deep breathing and general exercises, every day outdoor walks and right mental and emotional attitude are all of paramount importance in the regimen of pregnancy.

The Regimen for Wholesome Living, section I, is admirably adapted for all the needs of the pregnant mother.

SECTION XXXIX

Postnatal Feeding

Thanks to the educational influence of nature cure propaganda, a decided change for the better in baby feeding has taken place during the past ten years. Up to that time the "top cream mixture" was universally recommended by allopathic physicians and given to babies by trained nurses.

While in the meantime many physicians and nurses have adopted more natural methods, the "top cream mixture" is still too common and must be entirely abolished in order to safeguard the health of our little ones.

In the February, 1909, issue of the Nature Cure Magazine, I commented upon this subject as follows:

1. Bottle-fed Babies. Our food analyses disclose the interesting fact that the elementary composition of the ash of the milk of an animal is about the same as the composition of the ash of its body.

They also show that good cow's milk when normal comes closer to the requirements of the infant body than does inferior human milk.

Our tables of food analyses show that chemically the composition of cow's milk and of human milk is very much the same. Human milk contains a little less proteid and a little more sugar than cow's milk, and the latter is much richer in organic salts than the former. There is much more of the all-important sodium in cow's milk than in human milk and about twice as much calcium (lime) and iron (table p.100). This explains why rachitis is so common among babies, while never found among calves.

As we have learned, the elimination of poisonous acids
from the body depends on sodium. The building of the bony structures depends on lime; the oxygenation of the blood, on iron.

Many years of practical experience in the care of babies has convinced me that milk fresh from a healthy cow is greatly to be preferred, as nourishment for infants, to the impoverished milk of scrofulous mothers.* In this connection it is significant that one-half of all "civilized" mothers, thanks to unnatural food and drink, vaccination and poisonous drugs, are incapacitated for nursing their offspring.

* This may not be true in the future if our milk cows continue to be regularly subjected to tuberculin tests.

To one who has studied the comparative analyses of cow's milk and human milk, it is incomprehensible why the former, when given to infants, should be diluted and spoiled by large quantities of water, salt, soda and inorganic mineral lime (in the form of lime water).

This procedure, however, is still frequently recommended by physicians of the regular school. Undoubtedly, the great frequency of anemic and rachitic diseases, the darkening of the iris, appearance of scurf rim, and the signs of catarrhal conditions in stomach and bowels are caused by such unnatural feeding.

The following extracts are taken from an article entitled "Bottle-fed Babies", in the Ladies' Home Journal. It was written by Dr. Emelyn Lincoln Coolidge, of the Babies' hospital, New York. Thousands of mothers, on account of the high standing and excellent reputation of this family journal, undoubtedly have followed, without question or misgiving, the advice presented.

The formulas given below are for the average healthy baby, and are called "cream" or "top milk" mixtures.

"Food for the first month. With a spoon, or a tiny dipper which comes for this purpose, carefully skim off the top six ounces from a quart bottle of milk; to this add twenty-four ounces of water which has been boiled and cooled, and in which has been dissolved three teaspoonfuls of granulated or six of milk sugar; next add a pinch of bicarbonate of soda and a small pinch of salt; mix this all thoroughly, and pour enough for each feeding into ten separate bottle& Then cork the bottles family with cotton and either Pasteurize the milk or stand it on the ice.

"For the second month. Skim off six ounces of cream, then pour off three ounces of milk; add twenty-four ounces of water and the same amount of sugar, salt and soda as above; mix and bottle.

"For the third and fourth months. Cream, six ounces; milk, six Ounces; water, twelve ounces; barley or oatmeal gruel, twelve ounces; sugar, salt and soda as usual, etc.

Plain Milk Formulas

"Pour the entire quart of bottled milk out into a clean pitcher and then back into the bottle several times, thus thoroughly mixing the milk; then take:
"For the first month. Six ounces of milk, twenty-four ounces of barley-water, half a tablespoonful of granulated or one of milk sugar, a pinch of bicarbonate of soda; mix all well together and pour the proper number of ounces into separate bottles, and either Pasteurize or place on ice.

"For the second month. Nine ounces of milk, twenty-one ounces of barley-water, one tablespoonful of sugar, and a pinch of soda."

Physicians would never think of giving such advice as this, if they were acquainted with natural dietetics founded on exact and complete analyses made by food chemists of the nature cure school.

I have already called attention to the fact that food chemistry, whether practiced in allopathic colleges, in great sanitariums or by vegetarian food reformers, deals with proteids, starches, fats and sugars only, and leaves entirely out of consideration the all important mineral elements or organic salts of potassium, sodium, iron, lime and magnesium.*

*This was true at the time this article was published in the Nature Cure Magazine.)

On these five positive mineral salts, as we have shown, depend all the important vital functions of the human organism, while proteids, starches, fats and sugars serve only as building and fuel material.

The digestion of the proteid and carbohydrate foods, as well as the elimination of the waste matter resulting there from, depends upon the positive organic mineral salts.

Study carefully these recipes for baby feeding, taken from the Ladies' Home Journal, and compare the mixtures with the analyses of cow's milk and human milk in the accompanying tables.

Let us consider the "top milk" mixture, prescribed for the first month. The cream rising to the top is almost pure fat. The all-important mineral elements plus the nourishing milk sugar and proteids remain in the skimmed milk, which is looked upon as worthless and fed to the pigs.

Our food analyses (see tables in Volume III, Cook Book) show that the ordinary brands of flour are almost devoid of mineral elements. Furthermore, one teaspoonful of barley to one pint of hot water does not mean much in food values. Where in these six ounces of cream (fat) and twenty-four ounces of barley water is baby to get the necessary amount of sugar for fuel material, of proteid for tissue-building, of lime for bone-building, of iron for oxygen-carrying, and of sodium, magnesium and potassium for the processes of elimination?

It seems that these deficiencies are intended to be overcome by baking soda, mineral table salt and the lime water, so generally prescribed by physicians. Many times I have demonstrated that inorganic mineral salts, with the possible exception of a little table salt, should not enter the animal or human organism, that these salts must first be organized,
made alive in the plant or animal cell, before they are wholesome food for animals or human beings. I have shown that, taken habitually in the mineral form, these salts accumulate in the human body, act as irritants and poisons and reveal their presence in the iris of the eye.

I fail to understand why the tender and sensitive organism of the newborn infant should be encumbered with inorganic minerals while cow's milk contains them in ideal form, made alive first in the grasses and grains, then still more highly organized and magnetized in the body of the animal.

It is bad enough to give mineral sodium, lime and table salt to an adult, but it is little short of criminal to give them to babies under the guise of foods and medicines.

The cream mixtures are readily digested, because there is not much to digest. The fact that infants thus fed cry for food continually is good evidence that their needs are not satisfied. Babies fed with this sort of slop grow fat for a while. The watery food inevitably produces fatty degeneration. This for a season swamps the little body with unhealthy fat. But the first crisis which happens along often takes away not only the unnatural fat, but the baby also.

The artificial mixtures contain entirely too much water in proportion to nourishing elements. The resulting malnutrition and the constant irritation caused by the inorganic minerals result in chronic diarrhea or constipation.

**The Right Way**

The best food for the newborn and growing infant is undoubtedly the mother's milk, provided that she is herself in fairly good health. Unfortunately, many mothers are unable to nurse their offspring, and if a healthy wet nurse cannot be secured, other food must be provided.

The best substitute for human milk, without question, is cow's milk, fresh, pure and undiluted, as it comes from the animal.

"Why", indignantly exclaims the trained nurse, when we give these instructions, "undiluted cow's milk is altogether too rich, it is indigestible for baby; if the milk is not boiled or pasteurized, germs and bacilli will surely create infectious diseases".

To this we answer: Our analyses show that the difference in composition between cow's milk and human milk is not enough to affect the infant. The danger lies not so much in overfeeding on "rich" cow's milk as in underfeeding on watery milk and cereal dilutions, and in poisoning the little body with inorganic minerals.

As regards germ infection and the necessity for pasteurizing the milk, the menace to health and life is greater through
malnutrition than through germs and bacteria. Germs we
cannot escape, not even if we were surrounded on all sides by
walls of air-purifying and antiseptic materials.*

*Since the foregoing was written we have learned that low
vitality and morbid soil will develop perfectly normal
microzyma into so called disease germs.

One of the foremost French bacteriologists claims that in the
mouths of infants shortly after birth he has found almost every
disease bacillus known to medical science.

William Osler; M.D., to whom the English language is
indebted for the verb "to oslerize," says in The Principals and
Practice of Medicine on page 151, in the chapter on
Diphtheria:

"The presence of the Klebs-Loeffler bacillus is regarded by
bacteriologists as the sole criterion of true diphtheria, and as
this organism may be associated with all grades of throat
affections, from a simple catarrh to a sloughing, gangrenous
process, it is evident that in many instances there will be a
striking discrepancy between the clinical and the
bacteriological diagnosis."

In the first part of this sentence he states that bacteriologists
regard as the sole criterion for the diagnosis of diphtheria the
Klebs-Loeffler, or diphtheria, bacillus; in the last part of the
sentence he admits that this bacillus is found in even slight
catarrhal conditions, and he might add that it is found just as
frequently in the mouth and throat of healthy infants and
adults. This is a good example of "orthodox" scientific
reasoning.

If germs and bacilli of themselves could destroy health and
life, the human race would in a short time become extinct.
Disease germs are omnipresent. They permeate the tissues of
our bodies and in the intestinal tract swarm by millions.
Whether they prevail depends upon natural resistance,
or
reserve force, and upon the disease soils in the system. The air
we breathe is saturated with all sorts of disease germs or their
microzyma.

Since baby cannot escape germ invasion, the real problem is
how to increase the resistance of the little organism and how
to purify it of morbid matter so that disease germs will not
find anything to feed on.

Resistance depends largely upon proper nutrition. Diluted,
watery milk, contaminated by inorganic minerals, is not a
good nutrient; its nutritive value is still more reduced by
pasteurizing or boiling. Heating milk or any other proteid food
above 1500 F. coagulates the albumen, disorganizes organic
compounds, precipitates salts and dissipates the life elements.
This reduces the nourishing value and digestibility of the
milk.

Nature does not provide the young animal with boiled or
pasteurized milk, and we should not lower food values by such methods.*

* It is now admitted that pasteurization and boiling kills "newly discovered vitamins" which are the "life elements" constantly referred to in my earlier writings.

I do not wish to intimate, however, that scrupulous care and cleanliness should not be exercised in the selection and handling of the milk.

Wherever possible, secure the milk of a single healthy cow that grazes on green pastures or is fed on normal clean food mixtures. Milk from cows kept in stables and fed on brewery and distillery slops and other refuse should not be used.

Every vessel and utensil with which the milk comes in contact must be carefully scoured, submerged in boiling water, drained and kept in a light, airy place.

The nursing bottle, after each feeding, must be taken apart and carefully scrubbed, inside and out, in hot water with an addition of a little soda. It should then be left in pure, cold water, until the next feeding time.

2. When to Feed. Physicians quite generally recommend feedings at stated hours, in fixed quantities.

This is altogether wrong, it establishes at once the stuffing habit, does not permit the development of natural desire and its regulation. The infant very soon becomes accustomed to eating at certain times, whether it really needs the food or not.

Food should not be given until there is an actual demand for it, which will express itself in real hunger. By careful observation and experiment the mother will soon learn to distinguish the ordinary crying of the baby and the desire for food expressed by it. If this practice of feeding only when there is a natural desire for food is strictly followed, the infant will soon establish its own regular feeding times, usually at intervals of about three or four hours in the daytime. The stomach digestion of a feeding of milk will require about three hours, therefore a minimum of that much time should be allowed between feedings after the first few weeks.

If the mother can nurse her baby, it should be put to the breast upon awakening from its first sleep, either before or after bathing and dressing.

The first secretion of the breasts (colostrum) is not really a food, but performs an important function in cleansing the intestinal tract and preparing the digestive system to properly digest and assimilate the milk when it comes, usually about the third day.

3. How to Feed. If artificial feeding must be resorted to, no food at all should be given, except a few teaspoonfuls of water, during the first twenty-four hours after birth. During
the next few days, cow's milk should be given, well diluted—about one-half milk and one-half filtered or boiled water. From week to week the amount of water should be reduced until at the end of the second month the baby takes cow's milk undiluted.

4. Night Feeding. In the nighttime feeding should not be encouraged. During the first four months it is advisable to feed not more than once during the night. After that the child should be weaned from the habit entirely. This will be facilitated by giving a drink of water instead of milk.

5. Amount of Food. Discretion should be observed in determining the amount of food. Do not induce the baby to take as much as possible, rather as little as possible. Its welfare does not depend upon the amount of food consumed, but upon the amount which it can easily digest and assimilate.

When more food is given than the digestive organs can take care of, the entire mass may ferment and sour.

6. Grain Extracts. If undiluted milk proves too rich, grain water may be added. In order to prepare this, take clean grain as it comes from the field, crush it in a hand grain mill or a new coffee mill, take three tablespoonfuls of the crushed grain to one pint of cold water, and boil on the stove for one hour; or in the fireless cooker for two or three hours, in which ease use a little more water at the start. While the gruel is boiling over the fire, add enough water to allow for evaporation and absorption. When thoroughly cooked, strain the gruel through a fine cloth or sieve. Add one tablespoonful, or more if necessary, to each milk feeding.

When baby is constipated, add to the milk, grain extract made from oats, and frequently cool the bowels with cold water. This will cure the most stubborn constipation. If the bowels are too loose, add to the milk, extract made from barley or wheat.

The small particles of hulls in the grain extracts improve digestion and evacuation, in a mechanical manner. They permeate the curds and keep them from coagulating too solidly, thereby facilitating the penetration of digestive juices; they also exert a mild stimulation on the walls of the intestines, thereby increasing the peristalsis of the bowels and evacuation of feces.

7. Baby's Natural Medicines. Fruit juices and scraped raw ripe pear or apple and the pulp of cooked fruits such as prunes or figs without addition of sugar or sweetening of any kind, are baby's finest medicines. They increase the supply of organic salts for blood, nerve and bone building and for purposes of elimination. They are nature's own cholagogues, laxatives, tonics and antiseptics. They keep the little body sweet and wholesome. All babies under our care receive fruit juices beginning with the second week.
During the first two months, give one teaspoonful of orange juice, grape fruit juice or prune juice, one hour before or after each nursing. After the second month, gradually increase the amounts of fruit juices and begin to add raw pear or apple scraped with a spoon or dull knife, or the mashed pulp of fully ripened peach or grapes.

8. Weaning the Baby. Nursing infants should be weaned from the breast after the eighth or ninth month. From the sixth or seventh month, both nursing and bottle-fed babies should begin to take some solid food. The best of these to begin with are whole-grain cereals, gruels, raw and cooked fruits and tender vegetables in small amounts. Mealy baked potato is one of the best foods, better than the cereals.

9. Feeding After First Year. After the lapse of the first year, the solid foods are gradually increased and the milk reduced in quantity. Eggs should not be given before the eighteenth month, then soft-boiled or poached. During the second and third year half an egg twice or three times a week is sufficient; after that an egg at a time may be given once or twice a week.

Meat and all other foods prepared from the dead animal carcass are bad enough for adults, but it is inexcusable to give them to tender infants and children.

Dog fanciers, when they sell a valuable canine, usually advise the buyer not to give the animal any meat before the second year, lest it become a victim of distemper; and dogs are naturally meat eaters.

Well informed physicians now generally advise not to give meat to children before the fifth or sixth year. They have learned this much from the nature cure people.

Foods undoubtedly have a powerful influence, not only on the physical body, but also on the mentality and the emotions. These problems will be interesting subjects of investigation for the food chemist and psychologist of the future. In general, we may say that flesh foods are stimulating and feed the passional nature, while fruits and tender vegetables refine and stimulate brain and nerve matter as well as the intellectual, emotional and spiritual activities. Cereals, nuts and pulses build and repair the physical body and supply the body with heat and muscular energy.

The majority of animals adhere strictly to one kind of food, and therefore faithfully exhibit in their mental and emotional characteristics the effects of different food materials. Ferociousness we find personified in the carnivorous bulldog, lion, tiger and panther (that is why soldiers are fed on meat three times a day); gluttony and omnivorous voraciousness in the hog, chicken and hyena; cold-blooded cunning in the fox, and cruelty in the cat. The intelligence of the carnivorous animals displays itself mainly in the cruel cunning with which they stalk their living prey. It resembles in quality the low
intelligence of the human criminal.

Personifications of great physical strength, intelligence, endurance, patience, gentleness, fidelity, affection and self-control, we find among the vegetarian animals. The beaver, the arboreal ape and the elephant are especially noted for their intelligence; deer, antelope and sheep for gentleness; the horse for its almost human intelligence, affection and fidelity; oxen, elephants and camels for their great strength and endurance.

**Meat is detrimental to the child in every way**, physically, mentally and morally. The poisonous acids and alkaloids which it contains clog the capillary circulation, causing anemia, coldness of the extremities and defective elimination through the skin. This results in congestion in the interior organs, high blood pressure in brain and heart, headaches, nervousness, irritability, tendency to fevers, inflammations and catarrhal conditions.

With the meat, the child often absorbs the eggs of worms, tubercular bacilli, and other parasites and disease germs. Certain forms of epilepsy, St. Vitus’ dance and hysterical conditions are due to uric acid poisoning and to other pathogenic materials and ptomaines contained in flesh foods. Such patients, in times of crises, frequently emit pronounced odors of raw meat or uric acid. Strictly vegetarian diet, combined with other eliminative natural methods of treatment, cures the majority of these cases.

Most of these poisonous acids, alkaloids and ptomaines contained in the flesh of dead animals are powerful stimulants. I have frequently noticed that people who have abstained from meat for a long time, when they first partake of it again experience sensations and exhibit symptoms resembling those of alcoholic intoxication.

We have learned that these stimulating extractives of flesh foods chemically closely resemble caffeine, thein and nicotine. The use of one or more of these stimulants invariably creates a craving for the others. This explains why a heavy meat eater is usually a confirmed coffee drinker or inveterate smoker, and vice versa; and why we find it almost impossible to wean people from one of these stimulants as long as they persist in taking the others.

The legumes or pulses—peas, beans and lentils—are close seconds to meat in acid-producing qualities. Eggs contain considerable ready-made uric acid and a great deal of sulfur and phosphorus. These may become dangerous to the organism. For these reasons, meats, legumes and eggs are always danger foods for the child.

Children brought up on such foods will show the effects in nervousness, irritability, lack of self-control, craving for cigarettes and alcoholic stimulants. The most serious aspect of this question lies in the stimulative influence of meat poisons
on the sex centers. It is a well known fact, verified by close observation, that flesh foods stimulate the sexual passions to a marked degree. This tendency is greatly increased by the use of coffee, tea and alcoholic stimulants in the form of wines, liquors or medicines. If the sensitive nervous organism of a child is overwrought by these powerful irritants, there can be but one result; precocious sexual awakening.

From the third year the child may gradually adopt with slight appropriate modifications, a diet as outlined under Sec. I, No. 10, and Sec. X, No.7.

SECTION XL

Exercises in Infancy

1. Exercises in Infancy. Proper exercise is important from the very beginning of life. A baby will follow its natural instincts for exercise if allowed to do so, by working its arms and legs and writhing its little body in all directions, if not unduly hampered by tight clothing and bandages. A few nude air baths every day will afford excellent opportunity for baby's gymnastic stunts.

After he is a few months old he may be placed on his stomach, when he will exert himself vigorously by trying to raise his head, to turn around, or to raise himself with his arms. He will soon learn to roll over and to creep lie nay now be pulled up gently by his arms and lowered again a number of times in succession.

When three or four months old he may be lifted by one arm or by both arms; by the right arm and left leg, or by the left arm and right leg. When the baby is six or eight months old, he should be strong enough to rise from his back to a sitting position. This may be encouraged by holding down the feet. I have known a number of nature cure babies who at six months of age clung tightly to a stick while being lifted a few feet from the bed. Another good exercise greatly enjoyed by the youngsters is to roll them back and forth on a bed.

The average healthy child will secure ample exercise while learning to walk and run and while playing with simple toys or with other children; but this may be supplemented to good advantage by special exercises devised by the father and mother. Nothing is better for the health and happiness of both parents and children than to join in merry romp and play.

Between two and five years of age the child may be taught more difficult stunts, performed either by himself or with the assistance of the father or mother; but **swinging the child high overhead, throwing him up and catching and other dangerous tricks should be avoided.** They are risky and have very little effect in developing the body of the child. The best exercise at this age consists in outdoor play and games.
From the sixth year, the question of exercise becomes a more important one, especially since the children are confined for many hours in school rooms. If exercise at this time of life, through play and games and special gymnastics, is neglected, it may affect health, strength and efficiency of the child for life.

Those of good physique and ample strength may gradually take up and practice the exercises for adults outlined in sections XXI, XXII, XXIII, XXIV.

2. High Chair. A baby should not be put in a high chair until he is quite well able to hold the spine and head erect, and should never be left in a chair for any length of time. If a baby is forced to maintain a rigid, sitting position for a considerable time, before the bones and muscles are sufficiently developed, this may produce deformity of the spine. Maids and nurses, if not properly supervised, sometimes fasten a baby in a high chair and leave him there to take care of himself for long periods.

3. Toys. Since most babies have a habit of putting everything into their mouths, toys must be selected that can do no harm. They should have no paint, no sharp points or corners which might hurt the eyes or mouth, and must be of material which can be easily and thoroughly cleansed. Hairy and woolly playthings are unsafe, being unclean and germ carriers. Objects small enough to be swallowed must never be put within baby's reach. The simpler the playthings the better; a few clothespins, empty spools, or other simple objects are better than expensive toys.

SECTION XLI

Baby's Ailments

1. Hernia As a result of a weakly or sickly condition of the mother during pregnancy and of faulty prenatal management, many children are born ruptured. So far I have not known a single nature cure baby that was born ruptured. Such defects are due to weakness of the tissues. This results from mineral starvation. The tissue walls contain too much mortar (protein) and not enough building stone (mineral salts). Prevention of hernia, therefore, lies mainly in proper diet of the pregnant mother, but all the rest of the prenatal regimen described in these pages is of great importance in preventing this and other ailments and deformities.

There are three principal points at which rupture or hernia may take place in infancy—at the navel, in the groin, and at the line between the navel and the lower end of the sternum. Other kinds of ruptures are extremely rare.
2. Umbilical Hernia: This is a protrusion of the intestine at the navel. It is the most common rupture in infancy. Pulling on the cord during childbirth, urging at stool or violent crying may result in rupture. The umbilical ring first expands and this forms a pouch into which one of the folds of the small intestine protrudes.

Treatment: Of primary importance is the diet as outlined herein. The baby must have plenty of fruit juices in order to reinforce the mineral salts in the milk. Cold bathing is very beneficial. The rupture itself should be cleansed several times a day with warm water. This must be followed by a wash with cold water mixed with lemon juice. Gentle, passive exercise, such as raising, lowering and twisting the limbs from side to side, also raising and lowering the body while supporting the shoulders and head, is of especial value.

The rupture must be reduced and kept from protruding by placing over it a large button or other article of similar shape, wrapped in gauze and held in place by broad strips of adhesive plaster. The adhesive tape is fastened over the button crosswise and must be applied in such a manner as to draw the skin from all sides over the rupture. Instead of the button, a compress made of gauze may be laid over the rupture and held in place by one broad adhesive strip. The covering of the rupture must be removed and renewed every day in order to allow cleansing, as before described.

When the child is old enough to exercise by himself, he should be taught special movements of the body and the limbs which develop the muscles of the abdominal region.

3. Ventral Hernia. This occurs along the middle line of the body between the navel and the breastbone, sometimes below the navel. The rupture may not be larger than the size of a pea or small marble, and may disappear on pressure. The treatment is the same as that of umbilical hernia.

4. Inguinal and Scrotal Hernia: These occur in infancy or in adult life; sometimes the inguinal canal does not close after the descent of the testes from the abdominal cavity into the scrotum, and the intestine descends through the open canal, thus producing the rupture. These forms of hernia become aggravated by coughing. They can be reduced immediately with gentle manipulation while the patient is lying on his back. This kind of rupture may be distinguished from hydrocele by the fact that in reducing it goes back easily with a gurgling sound. Hydrocele is not affected by coughing. A hernia is opaque to transmitted light; hydrocele, transparent.

These ruptures should be protected with a well-fitting truss. This has to be removed daily for cleansing of the parts. Appropriate exercises, passive and active, together with cooling sitz baths and washes with cold water and lemon juice are the best remedies for these, as well as of other forms of rupture.
5. Congenital Hernia occurs in the form of inguinal hernia and has to be treated in the same way. Ruptures of any kind must be reduced and properly supported. Constipation and consequent urging at stool may cause or aggravate any form of hernia and must, therefore, be overcome by the right treatment described under section XXVI, No.1.

6. Colic. This is usually caused by indigestion due to overfeeding, improper feeding, or too frequent feeding. The intestines are distended with gas, giving rise to a severe pain. The baby cries sharply, alternately drawing its legs up to the body and kicking them away. One of the quickest means of relief is a small enema of warm water and gentle circular massage of the abdomen from right to left. Food should be withheld until the symptoms have disappeared. The giving of milk or other food may quiet the attack temporarily, but the pain is apt to return with greater intensity. Warm water may be given if the baby will swallow it.

A baby managed in the natural way prenatally and postnatally is not likely to suffer from this ailment. Constipated babies are more prone to it than others.

Colic may also be caused by sudden chilling. In that case a warm bath for five or ten minutes, followed by gentle body massage will bring about a warm reaction.

7. Convulsions. These cause a great deal of anxiety to the fond mother. They are always reflex symptoms of some slight or serious internal disturbance due to wrong management. They commonly result from some form of auto-intoxication caused by digestive disturbances, and the resulting systemic or drug poisoning. An inactive condition of the skin, bowels or kidneys will favor auto-intoxication and convulsions. If proper care is taken to keep the system pure, and the organs of elimination in active condition, convulsions will not occur.

The best treatment during an attack is a quick, cold rub all over the body; application of a whole body or trunk pack; gentle soothing magnetic massage, and neurotherapy treatment. These treatments draw the blood into the surface and relieve congestion in the brain and nervous system.

8. Ailments of Teething. Many ailments of children are laid to teething, but this is a mistake. Well managed, healthy babies go through the teething period without any trouble whatsoever. This is practically always true of nature cure babies. When, however, the little body is heavily encumbered with hereditary and acquired morbid materials, food poisons and disease taints, the process of teething will not run its natural course and may precipitate any form of disease crisis.

When teething is difficult, it is frequently associated with digestive disturbances. Diarrhea may alternate with constipation and vomiting is of common occurrence. The baby may be restless and fretful. He tries continually to bite on something in order to facilitate the projection of the teeth
through the hardened gums.

No teething lotions or soothing medicines of any kind should be given for the relief of pain in teething. They all contain poisonous sedatives which benumb and paralyze the nerves and have serious after effects upon the system. They usually contain opium in some form, or other narcotic drugs.

The only way to prevent these and other infantile ailments is to keep the little body as nearly normal as possible through the natural treatment described in these pages. If this is closely adhered to, it will prevent, in many cases, the development of even measles and other common eliminative infantile ailments.

During this critical period in the baby's life the diet must be extra light; starchy food should be reduced to a minimum and replaced by raw and cooked fruits and vegetables juices. Cooling sitz baths will help to keep the bowels active and to abate internal fever.

9. Acute Catarrhal Disease. Acute catarrhal diseases of infancy such as croup, cold in the head, acute bronchitis and whooping cough, are different forms of acute elimination through which Nature tries to purify the little body from hereditary and acquired accumulations of morbid matter, systemic poisons and disease taints.

In accordance with this conception of acute diseases, as purifying, healing efforts of Nature, we would not do anything to check or suppress elimination but cooperate with Nature in her purifying, healing efforts. How we do this has been fully explained in other parts of this volume. (Section VIII)

The natural treatment is very much the same in all acute inflammatory ailments. Feeding must be reduced to a minimum. If the baby does not insist upon eating, nothing should be given except water with acid or sub-acid fruit juices, such as lime, lemon, grape fruit and orange. If the temperature does not run high, say not above 100 or 102 deg, frequent ablutions with cold water at intervals of from one to two hours will be sufficient to promote heat radiation and elimination of morbid matter through the skin and other organs of elimination. If the temperature runs' higher, say between 102 and 105 deg, wet packs must be applied, and renewed when they become hot or dry.

The wet packs are of especial value in all kinds of cough; whether it be the ordinary cough, croupy cough or whooping cough. A whole body or trunk pack, with or without a throat pack, will give almost instant relief. In many instances where baby is making the night hideous for the anxious mother, with it's coughing, a well-applied whole body pack, or a combination trunk and throat pack, will relieve the coughing almost instantly, and induce restful sleep.
In serious cases it is always advisable to call in a natural therapist or some other drugless physician, if one can be reached.

The mother should not forget that all acute diseases, after they have once developed, must run their natural course. She must, therefore, not become impatient and lose faith in the natural treatment if it takes a week or more to cure a common cold in the head or an attack of bronchitis, or if it takes from two to eight weeks to cure a case of whooping cough. Serenity, patience and cheerfulness are the primary requisites of the nature cure physician.

PART IV

BABY BOOK

Natural Therapeutics has undoubtedly solved the problem of treating human ailments. All other schools and systems will in time have to adopt the natural way. It is the hub of the healing art; all therapeutic methods radiate from it like spokes from a wheel.

Natural Therapeutics, however, has something better to give than treatment of disease, and that is prevention of disease. If children were brought into this world in the manner ordained by Nature and reared in harmony with the teachings of natural philosophy, disease would soon be a thing of the past. Human beings would then enjoy good health and be as beautiful and perfect in their kind as are animals, which live in the freedom of Nature, guided by instinct and therefore in harmony with the laws of their being.

We must begin, then, with prevention, for prevention is always easier and cheaper, than cure. But where must we begin to study the prevention of disease? Some will say, "At birth, because that is the beginning of life." Not so: that would be too late. The mould is made and the foundation laid for health or disease, for happiness or suffering, for efficiency or deficiency, before the human being in process of creation sees the light of day.

"Then," it may be said, "we must begin with prenatal influence, for the physical, mental, emotional and moral habits of the mother influence powerfully the development of the new life she is carrying." True—but we must start earlier than that. The making of the human being begins with mating and conception. All subsequent development depends upon the right start.

SECTION XXXII

Heredity

1. Importance of Correct Mating. Of primary importance in the sacred rite of procreation, as already intimated, is mating. This should take place only between descendants of the same subrace, or of closely related subraces such as the Indo-Caucasian and Celtic.

If the racial descent of the marriage partners is so far removed that it has produced pronounced differences in racial
characteristic—as in the case of the swarthy Mexican and white skinned Englishwoman, or the dark eyed Magyar and blue-eyed Scandinavian—then procreation becomes miscegenation and degenerates into mongrelization of the offspring. Everywhere in the animal and human kingdoms Nature has set the mark of disapproval on the mongrel. The offspring of miscegenation is doomed to deterioration and extinction unless assimilation of the elements of a lower race by a higher takes place sparingly and gradually.

The law of racial purity may be summed up as follows: When a member of a higher race cohabits with a descendant of a lower race, the offspring of the union loses more or less the characteristics of the higher race and reverts in physical, mental and moral traits to the level of the lower race.

The constructive results of racial purity are evident in Hindus of the higher castes; in that portion of the Jewish race which in mating has faithfully adhered to the Law of Moses, and in the blond and blue-eyed remnants of the Indo-Caucasian and Celtic races in Northern Europe and North America. The destructive results of miscegenation are plainly evident in the mongrelized population of Mexico and everywhere in the half-breed and many kinds of mixed breeds. These usually fall below the physical, mental and moral standards of the parent stock, and almost invariably revert to the customs and habits of the inferior race.

2. Use Heredity. Use heredity deals with the transmission to offspring of acquired physical, mental and moral characteristics of the parents. According to this law as it has been formulated, the chances of the offspring for long life, health, mental efficiency and moral stamina, other conditions being favorable, are better in direct ratio to the advancing age of the parents at the time of conception. While this is contrary to popular opinion, which assumes that younger parents produce more perfect offspring than older ones, the fact of use heredity is proved, both in the animal and human kingdom, by common observation and statistical evidence.

The working of the law is based on the fact that the procreative elements of the parents, or rather the microzyma of those elements, cannot contain the impress of physical, mental and psychical characteristics which at the time of procreation were not developed in the threefold organisms of father and mother.

The age of the father at conception is called the "birth age" of the offspring and determines its birth rank. While the father and previous male ancestors, for reasons hereafter explained, seem to exert greater control over the mental and physical characteristics, the mother furnishes the nutrient soil for physical growth. This does not mean that she exerts no control over the mental and psychical characteristics of the offspring; in addition to her influence through use heredity she has added opportunities through prenatal influence and postnatal training.
According to this law, then, the chances of the offspring for excellent physical, mental and moral development become better as the age of the father at the time of procreation advances beyond thirty five; while the physical condition of the mother for reproductive function is best below thirty five years.

But we must not overlook the fact that too great a discrepancy of age between the man and woman may become the cause of physical and mental incompatibility, of aversion and great unhappiness, especially on the part of the younger woman.

Extensive statistical evidence seems to prove that the birth age of the mother has been of less importance than that of the father. As will be shown in Natural Eugenics, the majority of famous men in all lines or human endeavor had old male ancestors, while the mothers and previous female ancestors were of much younger age at the time of conception.

This may be accounted for by the following reasons:

The man is usually considerably older than the woman at the time of marriage. Men, as a rule, devote much more time and effort to acquiring a scientific, professional or business education than do women. This has been true in the past more than it will be in the future. Thrown early into the competitive struggle of life men generally have had to make greater mental and physical effort than have women.

These points are of considerable importance because it has been proved that it is not inherited brain mass and mental capacity, but strenuous and persistent effort that intensifies use heredity. The earlier this begins and the longer it continues before procreation takes place, the better the chances of the offspring for physical, mental and moral capacity.

The reproductivity of the mother has usually ceased at thirty-five. Though she be capable of childbearing a few years longer, usually conception has been avoided after that age. Men under favorable conditions remain reproductive to advanced age. Some of the world's greatest men descended from fathers over sixty years old.

That intellectual and creative capacity has followed the male line of descent rather than the female line, is indicated by the fact that the high intellectual capacity of many eminent men has skipped their daughters to reappear in male descendants. This may be partly accounted for by the fact that the daughters in their limited spheres of activity have not had the opportunity to unfold inherent intellectual capacity to any conspicuous degree.

There has been a tendency in some quarters to criticize the general entrance of women into professional and commercial life and to dilate upon the adverse influence this will have
upon womanly characteristics and family life.

In the light of the knowledge we possess upon the subject of use heredity, it is safe to say that any such problematical drawbacks will be far outweighed by the general postponement of the marriage age. This will insure not only better physical fitness but also higher intellectual development and greater moral stamina on both sides of parentage.

The tremendous benefits which this increased hereditary endowment will confer upon future generations cannot be overestimated. Greater intellectual and economic equality between the sexes will emancipate woman from degrading sexual subservience. Under the old order, sex appeal was too often her only stock in trade by which to attract and hold the male and thus to secure a living. Economic independence will insure greater consideration and higher esteem for the woman on the part of the man. It will go a long ways toward solving the problem of birth control in a natural way, by leaving it more largely to the judgment of the mother.

We find the law of use heredity according to birth age verified in the intelligence and moral development or obliquity of races, nations and tribes all over the earth—The lower the average birth age of a race or nation, the lower, other things being equal, the intellectual and moral development The greatest development and efficiency is found among those nations where marriage is delayed to a later age through custom, economic necessity, professional or military training.

The following quotation from "Control of Heredity", by Casper Lavater Redfield, is of interest in this connection:

"In general it may be said that wherever there are no restraints upon the sexual propensities, as with the Digger Indians, the Fuegians, the Andamanese, the Wauraus of the Guianas, the Bushmen and the tribes along the Gabbon river, there we find reproduction taking place at the earliest possible age, and the lowest grade of intelligence. Where we find some special circumstances or customs that delay the age at which reproduction takes place, as with the Patagonians, the North American Indian and the Polynesians, there we find considerably higher grade of intelligence.

"Where we find the custom of marrying late in life, as was customary with the Greeks and the Romans, there we find a very high grade of intelligence. And where we find a fortuitous succession of very late births, there we find the very great men of the world's history.

"In other words, the longer the time in which the individuals have in which to use, develop and strengthen their brains before reproduction begins, the greater and more powerful are the brains of their descendants."

In Volume IV of this Series I shall quote elaborate and
highly interesting statistics from Redfield, which reveal the effects of the various birth ages on physical, mental and moral characteristics. I shall confine myself, for the present, to the statement that, with few exceptions, the great artists, scientists, philosophers, statesmen and philanthropists were born from fathers whose ages ranged from forty to sixty-five years at the time of the procreation of their famous offspring.

The existence of these laws and principles as facts in nature is very evident in the training of racehorses and of other animals along certain lines of proficiency.

3. Pernicious Heredity. The effects of deteriorating and destructive heredity prenatal and congenital influences have been traced and commented upon in so many different ways that I do not believe it necessary to enter deeply into this phase of the subject. Various authors have filled entire volumes with the unsavory family histories of the descendants of the Jutes, Ishmaels and other drunkards, prostitutes, degenerates and criminals, which prove positively the transmission of morbid and pernicious traits through successive generations. It has been proved statistically beyond the shadow of a doubt that youthful delinquency, pauperism and criminality are the aftermath of immature marriages.

The laws of use heredity and prenatal influence, like all other natural laws and principles, manifest along opposite lines of expression. It remains for us to determine whether we shall align ourselves with their destructive or constructive activities. The effects upon ourselves and our offspring will show accordingly.

If I succeed in arousing the consciousness of prospective fathers and mothers to the glorious privileges and enormous responsibilities which these laws of nature confer upon them, then my labor will not have been in vain and I shall feel deeply gratified.

SECTION XXXIII

1. The Creative Alchemy of Love and Affection

Procreation—as is the case with everything else pertaining to the constituents and functions of the human entity—takes place on three planes of being, the material (physical and spiritual), the mental and the psychical planes. Which of these elements shall predominate in the offspring depends upon the mixture and adjustment of qualities in the triune makeup of the mating couple. In order to fulfill the law and to draw the divine blessing upon themselves and the fruit of their union the partners in the procreative function must be united by the bonds of love, or at least by the ties of true affection.
The source of creative genius is love and wisdom, and the essence of intelligence and power is sincerity and goodness. Without these, intelligence degenerates into selfish cunning, power into self-destructive brute force. The spring cannot rise higher than its source; its water cannot be pure and wholesome when contaminated by impure admixtures from filthy surroundings.

It is not generally known that use heredity pertains to intellectual and psychical qualities, as well as to the physical material. Animalism breeds nothing but selfish animalism. The vampire who craves and absorbs the love of its victims and robs them of vital energy, without being capable of feeling or bestowing affection, is the child of a discordant union—of brute animalism on the part of the man, of secret aversion and hatred, usually, on the part of the woman. These bestial and degrading tendencies on the one side, and unrequited love craving on the other, breed sex perversion, and propagate the harpies who delight in the seductive power of superficial beauty, while gloating over the weakness and ruin of their victims.

True love and affection, paired with intelligence and goodness; liberate the creative elements necessary to the production of perfect offspring.

The finer qualities of mind and soul open the fountains of life on the higher planes, liberate and harmonize the male and female procreative fluids, and charge them with the purest and most potent intellectual, spiritual and psychical elements.

The divine fire of creative genius burns only in the love aura of truly mated couples. It is true that these are rare under our artificial, unrighteous social institutions, and that accounts for the rarity of complete manhood and womanhood.

Perfect offspring, endowed with beauty and power of body, mind and soul, destined to shed through life a radiance of health, happiness and helpfulness—to love and be loved—issues only from the union of love and affection with intelligence and goodness.

"Love lieth at the foundation" (of all that is). "Love is passion, enthusiasm, affection, heat, fire, soul—God."

To the extent that love enters into the holy rite, to that extent its attributes will be absorbed in the threefold organism of the woman and become active in the child building in her womb. While she loves her man more than ever, her most passionate affection is centered in the new being in process of development. On it she bestows the purest and best in her food and drink, in her thoughts, emotions and secret desires. Fear, worry, anxiety, jealousy and hatred are strangers to her soul; these are the emanations of the lower spheres—she lives in heaven.

Somebody endowed with deep insight into these matters has
said:

"Whatever male and female shall truly will for, hopefully pray for and earnestly yearn for, when love pure and holy is the nuptive ascendant, in form, passional, affectional, divine and volitional, that prayer shall be granted, and the boon be given—but the prayer must precede."

What are the direct effects of the marital rite upon the participants? If the sex attraction operates on the physical material plane only, if lust instead of love presides at the matrimonial feast, then temporary gratification of erotic craving will be followed inevitably by monotony, satiety, gradual revulsion and aversion, culminating in a morbid craving for change and variety. The partners in carnal self-indulgence are intuitively aware of these tendencies to marital unfaithfulness, and, therefore, easily dominated by distrust and jealousy.

The procreative function is attended by complete satisfaction, buoyancy of body and mind and lasting happiness only when sex attraction operates on the higher and highest planes of being, as well as on the lower; when desire and impulse are operative on both sides. Thus only will the generative function fulfill its sacred purpose and confer the highest possible benefits upon parents and offspring.

The woman, being the more highly sensitized, must be responsive to the call of holy passion. To force unwilling compliance will ruin the woman, kill her love and curse her offspring. Balzac says: "He who begins with his wife by a rape is a lost man." It is impossible for a wife to love unless she is won, not forced to compliance.

2. Sexual Intercourse During Pregnancy. Sexual intercourse should be considered the most sacred function of the human entity. From the highest and best viewpoint it should be exercised only for the propagation of offspring. However, considering the present stage of ethical and moral development, temperate indulgence may not be wholly condemned. Excessive intercourse is always weakening and harmful to both participants. We must remember that the sex fluid is the carrier of the life force. It is that which constitutes strength, resistance to disease, initiative and genius. During abstinence from intercourse the sex fluids with their creative energy are absorbed through the inguinal glands into the organism and increase physical, mental, moral and spiritual capacity and energy.

Set rules for frequency of intercourse cannot be given. This must depend entirely upon individual conditions. One safe rule is that after indulgence there should be no feeling of satiety, weakness and exhaustion. The more frequent the indulgence the stronger will grow the power of habit and of passion and the greater will become the abnormal craving. It is the same with all other appetite and passions. The more frequently they are indulged, the stronger they grow, until
they attain complete control and develop into destructive habit

A free and confidential understanding in regard to these matters between those who contemplate matrimony would go far to prevent marital misery. A great deal of unhappiness arises from the fact that mates in the matrimonial union often labor under misapprehensions concerning the attitude of each toward the sex relation, and are prevented by excessive sensitiveness and delicacy from frankly discussing it. (For further discussion of this subject, see page 390, Volume I.)

There is no problem of married life that needs more thorough mutual consideration and understanding than this one. Lack of it accounts for a great deal of "incompatibility," loss of love, revulsion, hatred, and the final tragedy in the divorce court.

Among animals, no female allows intercourse after conception. In this respect as in many others, man has sunk below the natural standards of the animals. No greater crime can be committed against the woman and the unborn life.

It is a sad commentary on our system of education, scholastic as well as religious, that our young people are not instructed before and after marriage in these all important laws of Nature. To do this should be the province of the priest who unites them in marriage, or of the family physician, if the parents have failed in their duty.

It is well known (notwithstanding the denials of medical skeptics) that the unborn infant may be "marked" by transitory impressions, especially by strong emotions; that even insignificant parental characteristics are reproduced in the offspring. Is it any wonder, then, that the most powerful of human emotions should leave its impress on the growing brain and sex centers of the fetus, causing abnormal and precocious sex consciousness?

All too often is sex perversion born and bred in bone and flesh, before the child sees the light of day. The mother cannot be blamed for this "slaughter of the innocents"; she has not been instructed on the subject. Though she intuitively senses the horror of it, she submits, in order to maintain her hold upon the man—and many a life is thus cursed before it is born. The fault lies primarily with those of the medical profession who teach our young men that the free indulgence of sexual passion is not only legitimate, but a necessity to manly vigor.

This dictum of pseudo-science is almost universally concurred in by spiritual guardians. No greater lie was ever promulgated from the blackest abyss of Hades. If our young men were taught that greater happiness is to be attained by the exchange of tender affection than by the indulgence of the coarser animal appetites, that the creative forces thus preserved develop and strengthen their own finest capacities
of body, mind or soul, they would wisely and chivalrously protect mother and child, at the same time conserving their own physical and moral integrity.

In no other way is it possible to call forth the deepest gratitude and unfailing esteem of a true woman. Many a man whom we have thus advised has become a lifelong friend in consequence.

3. Limitation of Offspring. I believe that the unlimited production of offspring, encouraged in some quarters for swelling the ranks of religious bodies or for increasing tax paying and cannon-fodder material, is a misfortune, both to the family and to society. Limitation of offspring, in accordance with the means and circumstances of the parents, is not only justified but should be encouraged. In any case, the production of offspring entails great responsibility upon the parents and if they cannot properly comply with the needs and rights of their children, they fail in their responsibility and duty.

Any method, however, which interrupts intercourse or prevents conception in an artificial way, is absolutely to be condemned, because this has very harmful and positively destructive effects upon the physical, nervous and mental organism of those who thus try to cheat nature by the suppression of a natural process. In our professional work we frequently meet the victims of such pernicious practices. The ordinary contrivances for prevention make of intercourse something akin to masturbation. This is also true of intercourse without orgasm which is strongly advocated under various guises. The use of poisonous antiseptics and germ killers in warm water douches is not essential for prevention, and is highly injurious. These chemicals have a tendency to poison the sexual organs and to produce in time atrophy, many kinds of female disorders, and tumors. Undoubtedly the greater number of so called female troubles and malignant tumors in later life are caused by curetments, antiseptic douches and the use of poisonous drugs, for producing abortion. The only legitimate methods of birth control are abstinence or common cleanliness.

There is nothing more conducive to the physical, mental and spiritual health and development of a woman than childbearing and child rearing in harmony with Nature's laws, as outlined in these volumes. Under favorable conditions it is not a thing to be dreaded, but to be looked upon as the greatest of blessings and opportunities in the life of a woman. Natural philosophy and practice takes these problems of progeneration, childbearing and childrearing out of the domain of uncertainty and haphazard management with its dire consequences, and makes eugenics the most exact of all sciences and the sublimest and most enjoyable of all the arts.

4. Determination of Sex. Numerous theories have been advanced concerning this interesting subject. Many attempts have been made to wrest from Nature the secret of sex
determination and numerous more or less ingenious methods have been recommended for sex control.

I know of one method only which seems to have a rational basis and which has proved of practical value. Observations seem to prove that the right ovary liberates male ova only, while the left ovary discharges female ova. The two ovaries discharge ova only at alternate menstruations.

With this data at hand, it is possible to determine the sex of a child after one birth has taken place. Suppose the first child was a boy. By consulting our pregnancy table (page 377) we can determine when the last menstrual discharge took place. This menstruation liberated a male ovum; the next menstruation would liberate a female ovum, the next a male, etc.

Thus, using the last menstruation period before the last conception as a fixed point, it would be possible, figuring from period to period, to determine the sex nature of the ovum to be discharged at each following menstrual period. Account is taken of all regular periods during the time menstruation is suspended in pregnancy. Thus, conception may be timed in such a way as to impregnate at will a male or female ovum.

This solves in a simple, rational manner another of Nature's riddles, namely, the reason for the practically equal division of the sexes.

SECTION XXXIV

Prenatal Influence

There exists just as much diversity of opinion among scientists concerning the reality of prenatal influence as about race heredity, use heredity, disease heredity and many other mooted problems of science and philosophy, which we shall study in Vol. IV of this series. In the following I shall present and examine impartially the various theories and opinions concerning prenatal influence; then we shall be better prepared to draw our own conclusions.

1. Medical Science Denies Prenatal Influence. Medical men, as usual cocksure of the correctness of their theories and hypotheses based on the "latest discoveries", deny and ridicule the possibility of prenatal influence, and relegate it to the rubbish heap of popular superstitious. They base their judgment on the fact that no nerves pass from the body of the mother through the umbilical cord into the growing fetus in the placenta, which forms the soft protecting nest of the new life within the womb. They claim that since no direct nerve connection exists between the two, mental and emotional vibrations cannot be transmitted from the brain of the mother to the brain and nervous organism of the fetus.
Are there no other means of communication between the mind of the mother and the brain of the unborn!

In the volume dealing with Eugenics we shall learn how universal intelligence and creative will become individual intelligence and personal will.

Cosmic vibrations do not flow into the gray matter of the human brain over coarse physical nerve tracts. They come over the psychical wireless which connects the human soul with the world Soul, the individual intelligence with the universal or cosmic intelligence the human will with the divine will.

Since, as proved by modern brain and nerve anatomy, immaterial cosmic intelligence and "power to will" fashion the brain of the mother into physical material centers for the expression of human intellectual faculties, capacities and powers, why cannot these cosmic vibrations act in like manner over the psychic wireless through the soul and mind of the mother on the brain and nervous system of the fetal organism?*

These epoch making discoveries and revelations of modern brain anatomy are explained in Vol. IV of this Series, Natural Eugenics—Man Building on the Physical, Mental and Moral Planes.

Why should the wireless, which transmits impulses of intuitive intelligence from the great source of all intelligence and creative energy into the soul of the mother, cease to operate at that point, and fail to transmit its message to the brain and nervous system of the fetus which is most intimately related and connected with the organism of the mother?

What about the phenomena of hypnotism? Absolute control of the subject's mind, through the intelligence and will of the hypnotist does not depend upon the existence of an umbilical cord and physical nerve connection between the two. The hypnotist, by silent command, may call his subject from a distance, far beyond the reach of his voice.

People telepathically attuned may communicate in like manner, spontaneously, or by conscious intent. Why then should we doubt the possibility of vibratory correspondence between the mental and emotional conditions of the mother and the plastic nervous organism in process of development within her womb?

If a complexity of sound can impress itself permanently upon the wax cylinder of a phonograph, or what is still more marvelous, if the photographic rays of passing scenes can be fixed and retained in the picture film, why should it be impossible for the mental and emotional vibrations of the mother to impress and modulate the molecular and cellular constituents of the fetal brain and nervous organism?
I have compared this creative power of the mother mind to the process of electrotyping. As the particles of metal in suspension in the fluid adhere to the spoon that is to be coated with silver, so the atoms and molecules in the gray matter of the brain of the fetus group themselves in harmony with the thought forms and emotional vibrations of the mind and soul of the mother. While this mental and psychical electrotyping takes place automatically, the mother's brain and nerve molding power can be greatly strengthened and intensified by the conscious and voluntary operation of the psychical wireless that establishes vibratory oneness between her and the human entity in process of development within her own body.

Thus it is revealed how a brain prenatally refined, organized and fashioned may endow the nascent individuality with certain aptitudes and talents along established paths of cerebration. There surely will be less resistance along such lines of physical, mental and moral endeavor than along other lines not prenatally influenced and molded. Therefore I strongly advise mothers, pregnant with new life holding marvelous possibilities for good or evil, not to be influenced by the superficial reasoning of materialistic science, but to follow the sacred intuition and impulse of their own creative genius in this, the most holy function of their being. Every normally constituted mother is intuitively aware of this wonderful power, and is willing and anxious to exercise it when her consciousness has been aroused to the great possibilities and responsibilities which the divine privilege of motherhood confers upon her.

It is natural for us to admire a great artist who portrays the human form, true to life, on the painted canvas, or who fashions it from inanimate stone, metal or marble; how much more grand and godlike is the creative power of truly mated parents whose privilege it is to bring into the world, and to fashion according to their highest ideals, a human being endowed with life and intelligence, with the infinite possibilities of a new center of creative activity.

Yet many mothers, totally ignorant of their divine creative privileges and possibilities, victims of physically and morally degrading marriage relations, and often filled with secret aversion or open hatred for their marital companions, pass unwillingly through pregnancy and not infrequently seek to destroy the new life. When the unfortunate victim of such marital incompatibility, conceived in passion and developing under the worst possible influences of mental and emotional discord, comes to arouse the maternal instincts of affection and devotion, then fear, anxiety and worry, like a continual nightmare, haunt the unhappy mind of the mother and impress their discordant vibrations upon the sensitive films of infant consciousness.

Compare this condition of fear, apprehension and gloom in the mind and soul of an unhappy and unwilling mother, with the joyful and ecstatic state of mind of a mother conscious of
the creative power of her intelligent will, who, from the time of mating and procreation, with accurate prescience prepares the most favorable conditions, astrologically, prenatally and postnatally for the finest development of the physical, mental and moral characteristics of the future world citizen.

The loftiest exaltation of a creative genius working in dead clay and cold marble cannot approach the ecstasy of a mother who has acquired a knowledge of the great laws which make possible the development of a perfect human being, the embryo of a master, an angel, a being destined to be godlike in its faculties, capacities and powers!

In place of fear and anguish of soul, what joy to the mother who knows that it lies within her power to prevent disease and degeneracy in her offspring; that the development of the child depends solely upon her own intelligent effort! Nothing is left to accident. Child bearing becomes an exact science, the most beautiful and inspiring of all arts and professions. Under such conditions motherhood, instead of being the greatest of hazards and hardships, becomes a divine privilege and the highest achievement of human existence and endeavor. It falls short only of the creative work of the great Universal Intelligence whose instrument of creation is the mother.

2. An Example from History. Let us consider the oft-quoted example of Napoleon Bonaparte. His mother, Lutitia Bonaparte, while pregnant with the future military genius, accompanied her husband on a military expedition, sharing with him the hardships and excitement of camp life, and the marches and battles of a military campaign. If there be nothing in prenatal influence, is it not singular that Napoleon should have become one of the greatest military geniuses of all ages, while not one of his many brothers ever exhibited enough military ability to make an efficient corporal? What was it that favored or determined the birth of the great military prodigy under these circumstances? The ancestors of Napoleon's father were not professional soldiers, nor was the father especially interested in military matters before the conception of his gifted offspring.

The dominant influences, therefore, must have operated through the singular occupation and surroundings of the mother during this particular pregnancy.

Many similar striking examples have been cited in works on prenatal influence. I myself might add many convincing proofs from an extensive experience in medical practice; but time and space do not permit. Contributory evidence may be secured from many excellent works dealing with this vital problem in human life. I may be permitted to say that use heredity and prenatal influence are distinctly manifest in the physical and mental characteristics of our three children who were born at intervals of seven and five years. Each one of them clearly mirrors in his or her physical, mental and emotional peculiarities the predominant mental tendencies, occupation and surroundings of the parents during the
respective prenatal periods. Similar manifestations of prenatal influence may be observed in almost any family.

3. **Birthmarks.** Medical men of late deny also the possibility of "marking" the offspring by sudden fear or shock on the part of the mother during pregnancy. Incidents of this kind, however, are of such common occurrence that it is a waste of time to refute these flippant denials.

There are good reasons for believing that such marking is more likely to occur during the periods when the menstrual flow should take place, but is suspended.

It may be argued that to mention the possibility of marking to a pregnant woman will greatly increase the probability of electrotyping violent emotions upon her offspring; in other words, that the fear of the thing will help to materialize it. This may be true to a certain extent, but we must remember that sudden shock through fear or disgust may cause the mischief anyway, whether or not the expectant mother is aware of the possibility. Understanding a danger and being prepared for it seems the best protection. The pregnant woman should study carefully section XXX, dealing with mental and emotional causes of nervous diseases, and should learn to relax to any sudden surprise and thus neutralize unpleasant and fear arousing impressions. Self-control is the royal remedy and the key to mastership.

4. **Physical Influence.** Now that we have studied some of the more important hereditary mental and psychical prenatal and postnatal influences, let us see how the physical condition of the mother's organism influences the brain and nerve matter of the fetus in its last stages of development, and after birth.

Materialistic science teaches that brain matter exudes thoughts and feelings, as the liver excretes bile, or the stomach pepsin. Natural science proves that mind is superior to matter, that the new born ego, by the power of intelligent volition, must fashion in the gray matter of the brain the molecular groupings or centers for the expression of intellectual and emotional activities, such as language, music, numbers, scientific and philosophic speculation.

This means that active cerebration and brain molding do not begin until after birth. But it stands to reason that the work of the nascent intelligence may be greatly facilitated or impeded by the physical condition of the brain. It is reasonable to assume that intellectual and emotional vibrations will more easily shape the gray matter of the brain into new configurations when it has been prenatally refined, organized and developed along certain lines of cerebration by use heredity and by constructive prenatal influences.

There exists a remarkable similarity between the brain molding and memory building activities of the intelligent ego and the making of phonographic records and moving picture
films. Lifelike impressions of sounds and passing scenes can be made upon the phonographic and photographic mediums only when wax and film are in a highly refined and plastic condition. When impure of substance and coarse of texture they, are not sensitive and plastic enough to register and retain the subtle and highly complex vibrations of sounds and passing scenes. In order to receive and register a great variety and complexity of sounds, the wax on the phonograph cylinder must possess a certain degree of refinement, softness and plasticity. If it is too hard and coarse it registers the loud and coarse sounds only. Such a record cylinder, exposed to a beautiful symphony executed by a great orchestra, would register and reproduce only the shrill cries of the trumpet, the rattle of the snare drum and the booming of the big horns and bass drums. The softer sounds of string, wood and wind instruments and finer shadings of tone and rhythm would be lost. With increasing refinement and plasticity, more subtle and delicate sound vibrations will be retained and reproduced.

In like manner the sensitive gray matter of the cortex of the brain must be in a pure and plastic condition in order to receive and register the impressions and impulses coming through the sensory organs, the psychic intuition and the intellectual and emotional activities of the mind. Anything in the way of physical impurity or foreign matter that tends to clog the brain, or to feed it with waste and morbid materials, or with corroding poisons, will lessen the atomic and molecular motility of brain and nerve matter, and will interfere with, or impede, the groupings and subtle transformations involved in the fashioning of brain centers through mental and emotional influences.

If the nutrient blood which feeds the brain substance of the fetus be saturated with CO₂, the benumbing, paralyzing carbon-dioxide, with clogging uric acid or the destructive acids of phosphorus and sulfur, the gray matter cannot, respond to the subtle and complex impressions and impulses from without and within.

The purity or impurity of the plastic matrix of the cortex depends upon the materials absorbed from food and drink. If these are so constituted as to create in the system excessive amounts of clogging and corroding substances, then these food and drink poisons will have a benumbing and deteriorating effect upon the sensitive gray matter of the brain, as well as upon the coarser tissues in the joints, muscles and vital organs. There is a rheumatism of the mind as well as of the joints.

A brain asphyxiated and clogged with pathogenic materials cannot be alert and active; it is too dull and lazy to think; it would much rather sleep than work; it is incapable of doing its best when its tiny blood and lymph vessels are obstructed with waste and morbid deposits which prevent the oxygenation and drainage of its delicately organized cellular tissues.
This, of course, is true postnatally as well as prenatally. A brain originally capable of the highest and finest achievements of the human mind may become utterly worthless, and may degenerate into idiocy through food, drink and drug poisoning.

Medical men tell mothers they need not worry over prenatal feeding, because the placenta, the vascular bag which forms the nest of the new life, acts as a filter which purifies the blood before it reaches the fetus. Common sense and every day experience tell another story. Even the best in the blood of many mothers is bad enough to serve as food for the new life.

The placenta does not filter out of the blood of the mother all food, disease and drug poisons. This is proved by the wretched condition of many infants, suffering from malnutrition, anemia and rachitis, after delivery. If the vital fluids of the mother are deficient in the mineral elements, or in other important nutritive substances, how can they deliver them to the fetus?

Occurrences like the following, quite common in our institutional practice, prove positively that the placenta is not a perfect filter for systemic poisons and for disease taints circulating in the blood of the mother.

One of the most pitiable cases of eczema in a little child less than one year old we traced to the fact that the mother, during her first year of marriage, had traveled with her husband through Eastern European and Asiatic countries, and during her pregnancy had been vaccinated five times while passing through localities where smallpox was prevalent. Both she and her husband had always enjoyed perfect health. The family record was excellent as far as traceable; still the body of the infant soon after birth, was covered with open bleeding sores, presenting a revolting sight. We could find no explanation for this strange phenomenon other than the many vaccinations during pregnancy. These had contaminated the blood of the mother, and through her the body of the fetus, with a filthy scrofulous taint.

The baby suffered terribly. For many months it slept but little, because of the excruciating pains. The eczematous eruptions were of a very stubborn nature; they broke forth again and again. Finally, however, after eighteen months of natural treatment, we succeeded in purifying the little body of the horrible infection. The child is now a little over three years old, in perfect health, and during the last twelve months has shown no signs of the morbid taint.

Under another section I shall describe the influence of food upon character and sex life.

To recapitulate: Purity, plasticity and motility of the highly refined and sensitive materials which make up the gray matter of the brain depend upon pure food, plenty of fresh air and exercise, and upon all other natural methods of living.
SECTION XXXV

Conception and Pregnancy

1. Conception takes place whenever the male spermatozoon joins the female ovum (egg) within the woman's womb. Normally the female organism liberates from its ovaries but one ovum each month, usually during menstruation, while the male discharges millions of spermatozoa at each orgasm.

Conception does not always follow copulation. The ovum remains in the womb and is capable of impregnation for about five days after menstruation. The spermatozoon on entering the womb may meet an ovum which has been discharged at a previous menstruation, or it may remain alive in the womb for a number of days and finally come in contact with a newly discharged ovum at the following menstruation.

The spermatozoon retains its ability to impregnate the ovum for from ten to fifteen days after its discharge into the womb. When the male and female germs merge into one another, conception or impregnation takes place. As soon as this has happened, the impregnated ovum becomes attached to the inner lining or mucous membrane of the womb and begins its new life as an embryo. The period comprising the time from the impregnation of the ovum until the beginning of labor or childbirth is called pregnancy.

The table of pregnancy on page 377 indicates the probable date of normal termination of a pregnancy, calculated from the last menstruation.

2. Exercise During Pregnancy. Unfortunately a great many expectant mothers labor under the idea that they must rest and be relieved from work and exercise. This of course is a great mistake. Light housework is good exercise. There is nothing more harmful during pregnancy than nursing "that tired feeling" by lounging idly about the house and coddling one's real or imaginary aches and troubles.

Of great benefit to the pregnant woman are all outdoor sports such as tennis, golf and other games which require vigorous exercise without straining or overworking the body. The great benefit of walking and other outdoor exercises, aside from their general invigorating effects, lies in the strengthening of the abdominal muscles and ligaments, which at delivery will greatly facilitate expulsion of the fetus.

The walk should be brisk and rhythmical, body erect, head thrown back, chest forward; the breathing at the same time should be deep and regular. These walks should be continued as long as time and endurance permit. Nothing, of course,
must be pushed to the point of exhaustion. One good long walk every day is necessary; two are better.

We all understand the necessity for a plentiful supply of oxygen under ordinary conditions, and especially in time of illness. During pregnancy the demand for oxygen, as well as for mineral salts, is doubled or trebled on account of the needs of the rapidly developing organism in the womb of the mother.

These extra demands for oxygen and ozone must be supplied by systematic deep breathing, cold bathing, outdoor walks, etc. If circumstances do not permit the taking of outdoor exercise, deep breathing should be practiced as often as feasible, at the open window.

Next in importance among gymnastic exercises is the internal massage described under section XXI, No.16.

Those exercises are especially valuable which bring into play the abdominal muscles and the muscles and ligaments of the genital organs.

3. Clothing. Clothing and the manner of wearing it profoundly influences the normal or abnormal development of the fetus, the health of the mother, labor and delivery.

At no time should the waistline be constricted by a corset or even by the ordinary skirt band. All clothing should be as loose and light as possible—one-piece under and outer garments, with the weight suspended from the shoulders, are best. If skirts are worn they should be fastened to skeleton waists of some thin cotton material. The close, heavy texture of the material from which the corset or so called "reform waist" is made is injurious because it interferes with skin elimination.

Even the slightest constriction of the waist line interferes with the free circulation and the normal blood supply to the abdominal organs, which is of especial importance in pregnancy; it also hinders the free expansion and movement of the uterus during the various stages of pregnancy.

Within the waistline are located a dozen or more important vital organs of the body. Any sort of constriction compresses these organs and pushes them out of their normal position. While this is extremely injurious to the body of a woman under ordinary conditions, it is doubly so to the pregnant mother and to the rapidly growing fetus. Undoubtedly many deformities and monstrosities are produced by unnatural constriction of the blood vessels and vital organs in the abdomen and pelvis of the pregnant woman.

If due attention is paid to the foregoing influences, labor and delivery will be brief and easy. This we have proved in hundreds of cases which have come under our management. The reason why women of civilized countries spend many
hours and sometimes days in dreadful agony of childbirth while those of primitive or savage races, as we call them, produce their young easily and painlessly as the animals do, is that primitive women live more simple and natural lives, while "civilized" mothers violate practically every law of Nature in their daily habits of living.

Civilization unfortunately stands in many respects for that which is artificial, unnatural and therefore productive of disease and suffering in all domains of life, not only as regards physical health, but social and political health as well.

SECTION XXXVI

Danger Signs During Pregnancy

1. Dropsical Swelling. Swelling of the limbs and distention of the veins of the legs during pregnancy may be caused by a tendency towards varicosity, intensified by obstruction of the circulation due to the enlarged uterus. Such a condition requires, aside from the natural regimen, careful and competent treatment.

Swelling of the limbs or other parts of the body may also be caused by incipient or advanced Bright's disease. The urine should be examined from time to time, especially if there is a swelling of the feet and ankles, or if there are dropsical symptoms in other parts of the body.

Such dangerous conditions are usually brought about through the excessive intake of starchy and protein foods which overwork the liver and kidneys and cause pathogenic dogging of the capillary circulation. This may result in uremia attended by violent and sometimes fatal Convulsions.

2. Uremia is the result of retention in the system of waste materials and poisons that should be eliminated through the kidneys and skin. Medical treatment for such conditions, aside from the administration of stimulating drags, consists in hot bathing with the idea of opening the pores of the skin.

We understand that all hot water treatment gives only temporary relief and is followed by greater enervation and inactivity of the skin. The best water treatment for systemic poisoning of any kind consists in the application of wet packs followed by cold ablutions as described in section XV.

The addition to the packs, dry friction rubs, air bath, good massage and neurotherapy treatment will aid in restoring the normal activity of skin, bowels and kidneys.

Whenever the urine contains sugar or albumen, fasting, alternating with raw food diet, is indicated. Suitable regimens are outlined in sections X, XI.
The giving of heavy food to the mother with the idea of increasing the flow of milk is all-wrong. We have found in all cases that the diet outlined in section X will produce a more copious flow of rich milk than lie "nourishing" meat diet. The best remedy for a scanty flow of milk is slow and thorough mastication of a few spoonfuls of raw crushed wheat every day.

3. Morning Sickness. One of the common disorders experienced during pregnancy is that known as Morning Sickness. One suffering from this ailment, though following a natural diet, should sip a cup of hot postum while remaining in bed. If this does not have the desired effect and if the patient has not been accustomed to drinking coffee, half a cup of black coffee with a few drops of lemon juice will quiet the irritated nerves. It is necessary after taking the hot drink to remain in bed for at least thirty minutes. It is understood that this is only an emergency measure. If continued, it will lose its good effect and work injury.

SECTION XXXVII

Labor and Delivery

At about forty weeks, exactly nine solar months, from the period of conception the fetus reaches full maturity, and labor begins. Labor is divided into three stages. During the first stage the neck of the womb becomes slowly and gradually distended and the orifice of the womb opens widely. When this has taken place, the fetal membranes burst and the amniotic liquid surrounding the fetus escapes.

During the second stage the fetus emerges from the womb.

After expulsion of the fetus, the placenta is expelled from the uterine cavity. This constitutes the third stage of labor.

The first stage usually begins with more or less radiating pains in the abdomen, accompanied by dull pain in the small of the back and a drawing pain in the limbs. Sometimes women with the first baby feel these pains weeks in advance of the actual commencement of labor. At first they occur at long intervals and are of short duration, but gradually become more prolonged and more frequent. The pains are due to a cramp-like contraction of the muscular apparatus of the uterus forcing its contents downward.

Under this pressure from above, the neck and mouth of the uterus distend to their limits, and the walls become thinner and thinner. First the inner, then the outer orifice of the neck of the womb opens and the fetal membranes protrude and finally rupture, allowing the amniotic fluid to escape. Shortly after this the part of the fetus nearest the orifice, normally the
head, makes its appearance. At the present time the average duration of the first stage of labor is six hours, but it may last twenty-four hours or longer, depending upon the plasticity and elasticity of the bony structures of mother and infant, the rigidity of the cervix, and the vigor or lack of vigor of the muscular apparatus of the uterus.

While the foregoing is true of the average delivery under ordinary ways of living, we find that after the enforcement of a natural regimen of living during and, better still, before pregnancy, the entire period of labor and delivery does not cover more than half an hour, or at the utmost from one to two hours. Even the disadvantages of slight build and smallness of pelvis can be overcome by the natural regimen outlined in section X. When our youngest child was born, the mother gave the first sign of pain at about midnight. I rose from bed instantly, but had not time to finish clothing when the membranes broke. Within twenty minutes after the commencement of labor the infant was resting in my hands.

The wife of a prominent lawyer in a western city had experienced three difficult deliveries. Each time surgical instruments had to be used and she had suffered untold agonies lasting from 24 to 36 hours. When she became pregnant the fourth time the most prominent physicians in her home city assured husband and wife that it was not safe for her to go through another delivery, that the womb was in worse condition than ever before therefore they recommended surgical removal. For conscientious reasons, however, the husband and wife did not follow the advice of the doctors, but decided to try natural methods of treatment.

The lady placed herself under our care during the fifth month of pregnancy. From that time on she followed strictly the natural regimen of living and received daily the usual hydropathic and manipulative treatments. This was continued until a few weeks before delivery. In this case the baby was born within an hour from the first contraction, and the mother of the patient, who was in an adjoining room, had not heard a sound. Many similar experiences refute the idea that it is unsafe and injurious for pregnant women to undergo the ordinary methods of natural treatment, such as hydropathic sprays, sitz baths, massage, Swedish movement and other forms of manipulation.

1. Preparation for Delivery. The diet during the last week before the beginning of labor should be very light, consisting mostly of fruits and vegetables. From the commencement of labor no food at all should be given, until at least twenty-four hours after delivery; a three-day fast is better.

In addition to a competent physician, a nurse or midwife should be engaged. If a good neurotherapist, who has had sufficient experience in obstetrical work, can be procured, he should be preferred, because he can assist delivery and make it much easier by manipulative treatment.
The nurse will make the necessary preparations and provide the various supplies needed in labor. With the first sign of approaching labor, the physician in charge should be summoned. A rectal enema of one pint or more of warm salt water (See. XVIII, No.4) should be administered. The woman should be given a vigorous cold rub and her genitals thoroughly cleansed. She may then remain on her feet and walk about, comfortably dressed, until actual labor commences.

2. **No Anesthetics.** The attending physician should not be impatient to hasten delivery with drugs or instruments. The use of anesthetics should be avoided insofar as this is possible. They should be employed only when absolutely necessary—that is, when excessive pain must be allayed or when surgical delivery is unavoidable.

3. **Breaking of Water Bag.** When the bag of water is about ready to break, the patient is placed in bed. Premature discharge of the amniotic fluid must be guarded against. An escape of the liquid at an early stage means difficult and prolonged labor, commonly known as "dry labor". Usually the membranes burst when the orifice is fully dilated. A large sponge is held in readiness to catch the out-flowing liquid.

3 a. **Umbilical Cord.** When the infant has been delivered, the umbilical cord should not be severed at once. Plenty of time should be allowed for the blood to transfuse itself from the body of the mother to that of the child. This is important. If the connection is severed too soon, the child begins life in an anemic condition.

The newborn baby usually greets the world with a lusty cry. It should be placed on its right side with its face turned away from the mother, care being taken that the cord is not stretched tight. As soon as the cord stops pulsating, plenty of time being allowed for blood transfusion, it is tied about two inches away from the baby's abdomen and cut a little above the ligature. The baby is now wrapped in a warm blanket and put in its crib.

4. **After Delivery.** Immediately after the baby is born, the nurse or attending physician gently compresses the abdomen and womb of the mother, kneading and rubbing it occasionally in order to secure complete contraction and thus prevent hemorrhage. After delivery the mother enjoys a period of rest and recuperation which usually lasts for about half an hour.

5. **Afterbirth.** Meanwhile the placenta becomes detached, and when the pains set in again a few contractions usually suffice to expel it with all the membranes.

The attending physician must make sure that none of it is left in the body, since this might result in putrefaction of the remains and blood poisoning. The woman's genitals should be washed with clean sterilized water.
The exhausted woman should now enjoy a deep, wholesome sleep and awaken from it in a few hours refreshed and strengthened.

In the foregoing I have not gone into the details of obstetrics and of technical management because this must be left to a competent obstetrician. I have called attention only to those points which are of special importance from the viewpoint of Natural Therapeutics and to the differences in treatment between the conventional and natural methods.

6. The Lying-In Period. The lying-in period varies from five to twelve days, according to the constitution of the mother and the care that she has taken during pregnancy. The greatest danger of the lying-in period is puerperal sepsis or blood poisoning. This condition is the result of infection occurring during labor, or it may result from the retention of parts of the placenta.

The only way to prevent this is by observing the most scrupulous cleanliness during the entire process of childbirth and during the lying-in period. When blood poisoning has developed it must be treated the same as all other acute inflammatory diseases (see section IX).

7. Care of the Newborn. The child should begin to breathe immediately after the cord is cut. If it fails to do this, the physician should lift the baby by its feet to facilitate the escape of mucous from the trachea and throat. If necessary the mucous must be removed from the throat by the insertion of the little finger, or by means of a tiny stick covered with gauze.

Breathing may be accelerated effectively by a few sharp taps on shoulders and buttocks. If this fails to bring the desired result, artificial respiration must be resorted to at once. The attendant grasps the child by its shoulders, its head resting between his palms and the two index fingers being hooked under the child's armpits. It is now swung between the physician's legs and lifted high above his head so as to be turned upside down. This is repeated from fifteen to twenty times, after which it is placed in a basin containing a few inches of warm water. Its body should then be rubbed briskly with cold water.

Father Kneipp used to take the newborn babe by the nape of the neck and the feet and submerge it quickly in cold water. This, a few times repeated, is probably the quickest way of resuscitating an asphyxiated baby.

In order to soften the cheesy deposit which frequently covers the body of the newborn, it is well to rub the skin with warm olive oil. After the greasy covering has sufficiently softened it may be removed with bits of gauze. This is followed by a cleansing bath with warm water and castile soap.
After the warm cleansing bath, the little body should be quickly rubbed down with cold water, wrapped in a soft, warm blanket and laid away to sleep until it wakens of its own accord. A normal baby should sleep for about twelve hours, and must not be disturbed to force food on it before it is ready to take it.

8. **Bathing.** From the first day, the baby must have a morning and evening bath. This consists, as before described, in a quick, cleansing bath of warm water and castile soap, followed immediately by a brisk cold rub. In the course of a few weeks the baby can be placed, for the cleansing bath, in a small bathtub containing a few inches of warm water. Immediately after the cleansing bath the warm water is replaced by cold water. This is taken up in the hollow of the hand and briskly applied to the little body. In this fashion the child, within a few months time, will enjoy its cold rub just as much as an adult. I have seen several such nature cure babies, but a few months old, object most vigorously to a warm bath. The cold rub is the best preventive of chilling; but care must be taken that the temperature of the room where the bath is given is not below 70 deg.

The olive oil bath or rub, often recommended for premature babies or infants suffering from malnutrition, is very injurious, because it occludes the pores of the skin and prevents the elimination of poisonous gases and other morbid materials from the body. The skin is not an organ of digestion. Olive oil, like all other foods, must enter the body through the alimentary canal where, under the action of digestive ferments, it is broken down into its component elements which are then assimilated through the intestinal membranes. Oil absorbed through the skin is not digested, and it circulates in the body as foreign matter which in this state cannot be assimilated and utilized in the system.

9. **Powdering after the bath** is fully as injurious as the rubbing with oils or massage creams. Powders and creams tend to clog the pores, and most of them contain poisonous antiseptics which lower the vitality of the skin and prevent or suppress elimination in the form of skin eruptions, eczemas, etc. For chafing use nothing but cold water. In case the chafing should become unusually severe and painful, through neglect by the caretaker, a soothing and healing lotion composed of one part lemon juice to two parts olive oil, may be applied a few times, until the irritation is under control.

10. **Air Baths.** Next to cold water, there is nothing that will invigorate baby’s skin and nervous system as will the air and sun bath. If the season will not allow the outdoor air bath, the baby should be allowed to lie nude several times a day, for thirty minutes or more, in a warm, well ventilated and sunny room.

11. **Constipation.** Glycerin and suppositories should never be used; neither laxatives nor cathartics. Oat extract and cooling sitz baths will produce natural movements.
12. Diarrhea is a form of morbid elimination, and must never be suppressed by drugs. If it is habitual, bailey or wheat extract prepared in the same manner as oat extract, is a good remedy. If the diarrhea is persistent and of a violent nature, no food at all must be given, except water with dilute acid fruit juices, until the purging ceases. Even then plenty of time must be allowed for the rebuilding of the sloughed intestinal membranes.

13. Bandages. Until the umbilical cord dries up and falls off, it is necessary to cover the navel with a gauze compress dipped in olive oil. This is held in place by an abdominal bandage made of soft cotton material. These strips should not be hemmed, merely torn or cut. They should be drawn just snugly enough to hold the compress in place, but not tightly enough to interfere with circulation. The, navel must be cleansed and the compress renewed twice each day. After the umbilical cord has dropped off we no longer apply the abdominal bandage. This is contrary to common usage, but is the best practice. The abdominal bandage overheats the body and interferes with the free movement of the diaphragm and the circulation of the blood.

14. Clothing. The clothing of the infant should be loose and light and as simple as possible. Freedom of movement is very important; binding or pressure upon any part cannot help but interfere with the circulation, and otherwise produce injurious results. The clothes should be short, in order to allow the feet and legs free play. Light weight, porous cotton materials are best for both under and outer garments. A lightweight wool petticoat may be worn when absolutely necessary to provide sufficient protection for the baby. Cotton hose and bootees may be used, but under no circumstances should such articles be of wool, because it prevents free elimination from the skin. The baby's head should not be covered out of doors, except in severe weather. At no time should a veil be placed over the face, as it will cause the infant to reabsorb the poisonous exhalations from its own lungs. All clothing should be changed each day. No garment should be starched—such a practice is not only useless but harmful.

15. Diapers must be provided in sufficient number to allow thorough cleansing and drying. The wet diapers should be scalded in hot water and very thoroughly rinsed in several waters afterwards. They should then be dried in the open air and sunshine. Soiled diapers must be well washed and boiled. Washing powders, soda, ammonia and other chemicals should never be used. They have an extremely irritating effect upon the delicate skin of a baby. In order to save labor and to facilitate the cleansing of the diapers, small squares of clean old linen or muslin rags, or pieces of absorbent gauze, may be placed inside. These inserts will absorb all or most of the bowel movement and may then be burned. If the skin is irritated or chafed, the parts should be sponged off with clean cold water at each change, paying special attention to cleansing of the genitals. Oils or powders must not be used to soothe the sore places, because they clog the pores and
Interfere with natural elimination.

16. A wet nurse is to be preferred to artificial feeding. She should be thoroughly healthy, not over thirty years of age, of equitable temper, not excitable or nervous and her diet should be that prescribed for the mother.

17. Care of the Nipples. They should be thoroughly cleansed before and after nursing; not with carbolic acid, but with water and dilute lemon juice. The lemon juice tends also to harden the nipples. Treatment of the nipples may begin before the birth of the child.

18. Care of the Eyes. The baby's eyes, whether awake or asleep, should always be shielded from strong light, either sun or artificial, and from dust and wind. The eyes should be washed with cold water after every cleansing bath. If they show any tendency to weakness or disease, slight vibratory massage over the closed eyelids should be given after the cold eye bath.

19. Care of the Mouth. A healthy baby's mouth needs no cleaning before the arrival of teeth. As a matter of fact, the teeth of a perfectly healthy adult would not need cleaning any more than do those of an animal living in the freedom of nature. The saliva is a sterilizing fluid, under normal living, intended by Nature to keep the mouth clean and healthy. Cleansing of the mouth of an infant with the finger or with a cloth may injure its delicate membranes. If the mouth must be washed, in case of disease, a swab made by twisting a piece of sterilized absorbent cotton on the end of a smooth stick should be used. The swab should be dipped in warm boiled water, and the interior of the mouth washed thoroughly, the cotton then being burned.

20. Care of the Ears. The external ear should be cleansed with a soft rag or swab as before described. Never use a hard instrument inside the ear.

21. Care of the Nose. A baby's nose should be cleansed as a part of the daily toilet, in the same way as the ears. A swab may be made by twisting a, piece of gauze to a cone. As soon as the child becomes old enough, it should be taught to sniff up cold water through the nostrils and the nasal passages. This is the best way to keep the nasal membranes in a clean, healthy condition.

22. Care of the Genital Organs. The genital organs of both sexes must be kept scrupulously clean with as little handling as possible. The foreskin of the penis of the male baby should be drawn back at bathing time and the organ thoroughly cleansed, always finishing with cold water.

23. Phimosis. The treatment of phimosis is fully described under Sec. XXVIII, No.1.

24. How to Lift the Baby. The best way to lift a young
baby is to slip the left hand under the back beneath the shoulder, spreading out the fingers in such a way as to support the neck and head. Then lift the feet and legs with the right hand. *Never lift an infant without first supporting the spine.*

When a baby has grown strong enough to hold up its head and has gained considerable strength in the muscles of the back and neck, he may be lifted by grasping him with outspread fingers under the armpits; the body must be held firmly so that the entire strain does not come on the shoulders. A baby should never be lifted by the arms. This may dislocate the shoulder joints.

**SECTION XXXVIII**

**Prenatal Feeding**

1. **Effects of Diet During Pregnancy.** The problem of infant nutrition begins before birth. Prenatal feeding determines the physical start in life. On it depends not only the condition of the mother's health during pregnancy, but also the size and weight of the fetus, pliability of the bony structures, ease or difficulty of delivery, and the quality of the mother's milk.

The fleshier and heavier the newborn infant, the prouder and happier are the parents and the doctor. Yet, excessive size and weight of the child constitute the most prominent cause of difficult and painful childbirth and frequent necessity for instrumental delivery.

The biblical saying, "In sorrow thou shalt bring forth children"; has led many to believe that woman's dreadful suffering is a necessity, God ordained; but is not man's ignorance, rather than the cruelty of an avenging God, to blame?

This latter view is confirmed by the fact that other mammalia literally cast their young, without pain or difficulty; and the labor pains of primitive mothers are insignificant, their delivery presenting little more difficulty than that of the lower animals. A squaw on the Western Plains stops a few hours by the wayside to deliver her papoose and then resumes her journey as though nothing had happened.

Women among the European peasantry, who wear no corsets, live on black bread and vegetables, and have plenty of exercise in the fields and in the home to the last day of pregnancy, have their babies without help of midwife or physician and resume their usual routine of work within a few days after delivery.

Thousands of mothers who have adopted natural ways of
living have learned to dispense with anesthetics and the surgeon's instruments; they now bring forth their offspring without excessive pain.

2. Results of Faulty Diet. It is significant that the offspring of the lower animals, at birth, consist of little more than skin and bones, while the newborn human is often abnormally large and fat. This is especially true of babies born of weak and anemic mothers. As before stated, excessive size and weight of the infant is not a matter for congratulation, but is a pathological condition. It indicates fatty degeneration of the fetus, due to the anemic watery condition of the blood of the mother, and the cause of this hydremia of mother and child lies in the faulty dietetic habits of the former.

The ordinary diet of American women consists almost entirely of meat, fish, fowl, potatoes, white bread, pastry, coffee, tea and refined white sugar. The few vegetable, which enter into the daily dietary are first deprived of their all important organic salts by faulty cooking; fruits are looked upon as luxuries and frequently are regarded as harmful

The anemic, watery condition of the blood of mother and child is not due to a lack of starchy, protein and fatty materials in food and blood, but to a deficiency of organic mineral elements. Neither is the anemic condition, as the regular school of medicine assumes, caused by lack of iron. Any ordinary food mixture, as well as the blood and milk of anemic mothers, usually contains a sufficient amount of iron. The actual cause of the anemia is a deficiency of other mineral elements.

As I have explained in Volume III of this Series, carbonic acid poisoning and the resulting sluggishness of the surface circulation, coldness of the extremities and congestion of the inner organs is not caused so much by a lack of the oxygen-carrying iron as by a deficiency of the carbonic acid neutralizing and eliminating sodium and magnesium.

If the blood is deficient in lime, phosphates, silicon and fluorine, rachitic conditions, softening of the bones, deformed spines and legs, and decay of the teeth, are inevitable results.

It is an easy matter to supply the daily needs of the organism for proteids, starches, fats and sugars; the difficulty lies in supplying a sufficient amount of the organic mineral elements.

The deficiency of sodium in human blood, Dr. Lahmann proved in the following table of comparative blood analyses.

<table>
<thead>
<tr>
<th>Per Cent of Sodium</th>
</tr>
</thead>
<tbody>
<tr>
<td>Blood of oxen</td>
</tr>
<tr>

<tr>
<td>Blood of cows</td>
</tr>
<tr>
<td>Blood of hogs</td>
</tr>
</tbody>
</table>
Blood of dogs | 2.02 to 5.78
Human blood | 2.03 to 6.27

The percentages of lime and of other positive mineral elements in the human blood are also much lower than in the blood of cows, oxen and sheep.

While the blood of cattle and sheep raised on pasture is very uniform in composition, hardly any two samples of human blood are alike. It is for this reason that Dr. Lahmann adopted cow's milk instead of human milk as the standard elementary food combination.

In the following table, he compares the percentages of minerals in the ash of cow's milk with the percentages of mineral elements in the ash of various other food materials.

</table>

A daily dietary consisting largely of meats, eggs, white bread, potatoes, peas and beans, though excessively rich in proteids, fats and starches, will, on account of its deficiency in sodium, lime and magnesium, inevitably result in carbonic acid poisoning, anemia, rachitis, premature decay of the teeth and a multitude of other acute and chronic ailments.

If, however, the daily dietary contains a liberal amount of green vegetables and fruits, a normal food mixture resembling that of cow's milk can easily be obtained. It must be remembered that fruits and vegetables are not only rich in the most important mineral salts, but that they are relatively poor in proteids and carbohydrates.

For this reason fruits and vegetables facilitate the establishment of an equilibrium between proteids and carbohydrates on the one hand and organic mineral salts on the other.

3. Excessive Fat Formation. We can now understand why the ordinary faulty diet of pregnant mothers causes anemia, softening of the bones, sluggish circulation, carbonic acid poisoning and fatty degeneration in mother and offspring.

Lack of sodium causes excessive accumulation of carbonic acid, and oxygen starvation. This results in defective
oxidation of food and waste materials; in other words, in fat formation.

Defective draft prevents the complete consumption of coal, and chokes the furnace with the products of imperfect combustion. Similarly, lack of oxygen in the tissues (due to carbonic acid poisoning) causes an incomplete combustion of food materials and waste products, resulting in fat formation and in the generation of poisonous byproducts.

Lack of sodium also prevents the neutralization and elimination of uric and other acids and ptomaines (pathogenic matter) which accumulate in the tissues, block the circulation and assist in the smothering of the vital processes.

In order to eliminate these pathogenic materials, there arises an abnormal craving for water—"the anemic thirst"—which is closely related to the thirst of fever patients and of diabetics. Excessive water drinking is encouraged by the popular "flushing" fad.

To make things worse, the anemic, for reasons before stated, usually suffers from weak heart action and sluggish circulation. This means defective elimination of water through the skin and kidneys, resulting in a watery (dropsical) condition of the tissues and fatty degeneration.

Not all anemic, carbonic-acid-poisoned mothers, however, develop a tendency to obesity. On the contrary, under certain constitutional conditions, they may become exceedingly lean, like the anemic, carbonic-acid-poisoned consumptive. Briefly stated, sluggish heart action and weak kidneys favor retention of carbonic acid and water in the tissues and thus make for fatty degeneration. Good circulation and normal activity of the kidneys may keep the system free from excess of water and carbonic acid, but excessive proteids in the diet may result in sulfuric and phosphoric acid poisoning. These destructive acids break down the tissues, rob them of their mineral constituents, and thus cause excessive loss of flesh and fat.

In both types of dysemia the blood of the pregnant mother is overloaded with poisonous gases, waste matter and the debris of broken-down tissues. The oxygen supply to the fetus is therefore very much impeded and we find that both fleshy and lean mothers produce babies of abnormal size and weight, ranging from eight to twelve pounds, while the normal weight of the newborn should not be more than six pounds.

4. Advantages of Natural Regimen. We know of many instances where mothers, after having given birth to heavy, fleshy babies, in subsequent births have reduced the weight of the new born to normal, and the pain of delivery to a minimum, by the adoption of a natural diet, plenty of exercise in the fresh air and systematic deep breathing.
The effects of a natural regimen are manifested in various other ways. The bony and muscular structures of mother and child are much more pliable and elastic, making parturition and delivery much easier. Pure blood, normal nutrition and abdominal exercises, walking and special gymnastics, greatly strengthen the abdominal and uterine muscles, thus facilitating expulsion of the fetus.

The morning cold rub, systematic deep breathing and general exercises, every day outdoor walks and right mental and emotional attitude are all of paramount importance in the regimen of pregnancy.

The Regimen for Wholesome Living, section I, is admirably adapted for all the needs of the pregnant mother.

SECTION XXXIX

Postnatal Feeding

Thanks to the educational influence of nature cure propaganda, a decided change for the better in baby feeding has taken place during the past ten years. Up to that time the "top cream mixture" was universally recommended by allopathic physicians and given to babies by trained nurses.

While in the meantime many physicians and nurses have adopted more natural methods, the "top cream mixture" is still too common and must be entirely abolished in order to safeguard the health of our little ones.

In the February, 1909, issue of the Nature Cure Magazine, I commented upon this subject as follows:

1. Bottle-fed Babies. Our food analyses disclose the interesting fact that the elementary composition of the ash of the milk of an animal is about the same as the composition of the ash of its body.

They also show that good cow's milk when normal comes closer to the requirements of the infant body than does inferior human milk.

Our tables of food analyses show that chemically the composition of cow's milk and of human milk is very much the same. Human milk contains a little less proteid and a little more sugar than cow's milk, and the latter is much richer in organic salts than the former. There is much more of the all-important sodium in cow's milk than in human milk and about twice as much calcium (lime) and iron (table p.100). This explains why rachitis is so common among babies, while never found among calves.

As we have learned, the elimination of poisonous acids
from the body depends on sodium. The building of the bony structures depends on lime; the oxygenation of the blood, on iron.

Many years of practical experience in the care of babies has convinced me that milk fresh from a healthy cow is greatly to be preferred, as nourishment for infants, to the impoverished milk of scrofulous mothers.* In this connection it is significant that one-half of all "civilized" mothers, thanks to unnatural food and drink, vaccination and poisonous drugs, are incapacitated for nursing their offspring.

* This may not be true in the future if our milk cows continue to be regularly subjected to tuberculin tests.

To one who has studied the comparative analyses of cow's milk and human milk, it is incomprehensible why the former, when given to infants, should be diluted and spoiled by large quantities of water, salt, soda and inorganic mineral lime (in the form of lime water).

This procedure, however, is still frequently recommended by physicians of the regular school. Undoubtedly, the great frequency of anemic and rachitic diseases, the darkening of the iris, appearance of scurf rim, and the signs of catarrhal conditions in stomach and bowels are caused by such unnatural feeding.

The following extracts are taken from an article entitled "Bottle-fed Babies", in the Ladies' Home Journal. It was written by Dr. Emelyn Lincoln Coolidge, of the Babies' hospital, New York. Thousands of mothers, on account of the high standing and excellent reputation of this family journal, undoubtedly have followed, without question or misgiving, the advice presented.

The formulas given below are for the average healthy baby, and are called "cream" or "top milk" mixtures.

"Food for the first month. With a spoon, or a tiny dipper which comes for this purpose, carefully skim off the top six ounces from a quart bottle of milk; to this add twenty-four ounces of water which has been boiled and cooled, and in which has been dissolved three teaspoonfuls of granulated or six of milk sugar; next add a pinch of bicarbonate of soda and a small pinch of salt; mix this all thoroughly, and pour enough for each feeding into ten separate bottles. Then cork the bottles family with cotton and either Pasteurize the milk or stand it on the ice.

"For the second month. Skim off six ounces of cream, then pour off three ounces of milk; add twenty-four ounces of water and the same amount of sugar, salt and soda as above; mix and bottle.

"For the third and fourth months. Cream, six ounces; milk, six Ounces; water, twelve ounces; barley or oatmeal gruel, twelve ounces; sugar, salt and soda as usual, etc.

Plain Milk Formulas

"Pour the entire quart of bottled milk out into a clean pitcher and then back into the bottle several times, thus thoroughly mixing the milk; then take:
"For the first month. Six ounces of milk, twenty-four ounces of barley-water, half a tablespoonful of granulated or one of milk sugar, a pinch of bicarbonate of soda; mix all well together and pour the proper number of ounces into separate bottles, and either Pasteurize or place on ice.

"For the second month. Nine ounces of milk, twenty-one ounces of barley-water, one tablespoonful of sugar, and a pinch of soda."

Physicians would never think of giving such advice as, this, if they were acquainted with natural dietetics founded on exact and complete analyses made by food chemists of the nature cure school.

I have already called attention to the fact that food chemistry, whether practiced in allopathic colleges, in great sanitariums or by vegetarian food reformers, deals with proteids, starches, fats and sugars only, and leaves entirely out of consideration the all important mineral elements or organic salts of potassium, sodium, iron, lime and magnesium.*

*This was true at the time this article was published in the Nature Cure Magazine.)

On these five positive mineral salts, as we have shown, depend all the important vital functions of the human organism, while proteids, starches, fats and sugars serve only as building and fuel material.

The digestion of the proteid and carbohydrate foods, as well as the elimination of the waste matter resulting there from, depends upon the positive organic mineral salts.

Study carefully these recipes for baby feeding, taken from the Ladies' Home Journal, and compare the mixtures with the analyses of cow's milk and human milk in the accompanying tables.

Let us consider the "top milk" mixture, prescribed for the first month. The cream rising to the top is almost pure fat. The all-important mineral elements plus the nourishing milk sugar and proteids remain in the skimmed milk, which is looked upon as worthless and fed to the pigs.

Our food analyses (see tables in Volume III, Cook Book) show that the ordinary brands of flour are almost devoid of mineral elements. Furthermore, one teaspoonful of barley to one pint of hot water does not mean much in food values. Where in these six ounces of cream (fat) and twenty-four ounces of barley water is baby to get the necessary amount of sugar for fuel material, of proteid for tissue-building, of lime for bone-building, of iron for oxygen-carrying, and of sodium, magnesium and potassium for the processes of elimination?

It seems that these deficiencies are intended to be overcome by baking soda, mineral table salt and the lime water, so generally prescribed by physicians. Many times I have demonstrated that inorganic mineral salts, with the possible exception of a little table salt, should not enter the animal or human organism, that these salts must first be organized,
made alive in the plant or animal cell, before they are wholesome food for animals or human beings. I have shown that, taken habitually in the mineral form, these salts accumulate in the human body, act as irritants and poisons and reveal their presence in the iris of the eye.

I fail to understand why the tender and sensitive organism of the newborn infant should be encumbered with inorganic minerals while cow's milk contains them in ideal form, made alive first in the grasses and grains, then still more highly organized and magnetized in the body of the animal.

It is bad enough to give mineral sodium, lime and table salt to an adult, but it is little short of criminal to give them to babies under the guise of foods and medicines.

The cream mixtures are readily digested, because there is not much to digest. The fact that infants thus fed cry for food continually is good evidence that their needs are not satisfied. Babies fed with this sort of slop grow fat for a while. The watery food inevitably produces fatty degeneration. This for a season swamps the little body with unhealthy fat. But the first crisis which happens along often takes away not only the unnatural fat, but the baby also.

The artificial mixtures contain entirely too much water in proportion to nourishing elements. The resulting malnutrition and the constant irritation caused by the inorganic minerals result in chronic diarrhea or constipation.

The Right Way

The best food for the newborn and growing infant is undoubtedly the mother's milk, provided that she is herself in fairly good health. Unfortunately, many mothers are unable to nurse their offspring, and if a healthy wet nurse cannot be secured, other food must be provided.

The best substitute for human milk, without question, is cow's milk, fresh, pure and undiluted, as it comes from the animal.

"Why", indignantly exclaims the trained nurse, when we give these instructions, "undiluted cow's milk is altogether too rich, it is indigestible for baby; if the milk is not boiled or pasteurized, germs and bacilli will surely create infectious diseases".

To this we answer: Our analyses show that the difference in composition between cow's milk and human milk is not enough to affect the infant. The danger lies not so much in overfeeding on "rich" cow's milk as in underfeeding on watery milk and cereal dilutions, and in poisoning the little body with inorganic minerals.

As regards germ infection and the necessity for pasteurizing the milk, the menace to health and life is greater through
malnutrition than through germs and bacteria. Germs we cannot escape, not even if we were surrounded on all sides by walls of air-purifying and antiseptic materials.*

*Since the foregoing was written we have learned that low vitality and morbid soil will develop perfectly normal microzyma into so called disease germs.

One of the foremost French bacteriologists claims that in the mouths of infants shortly after birth he has found almost every disease bacillus known to medical science.

William Osler; M.D., to whom the English language is indebted for the verb "to oslerize," says in The Principals and Practice of Medicine on page 151, in the chapter on Diphtheria:

"The presence of the Klebs-Loeffler bacillus is regarded by bacteriologists as the sole criterion of true diphtheria, and as this organism may be associated with all grades of throat affections, from a simple catarrh to a sloughing, gangrenous process, it is evident that in many instances there will be a striking discrepancy between the clinical and the bacteriological diagnosis."

In the first part of this sentence he states that bacteriologists regard as the sole criterion for the diagnosis of diphtheria the Klebs-Loeffler, or diphtheria, bacillus; in the last part of the sentence he admits that this bacillus is found in even slight catarrhal conditions, and he might add that it is found just as frequently in the mouth and throat of healthy infants and adults. This is a good example of "orthodox" scientific reasoning.

If germs and bacilli of themselves could destroy health and life, the human race would in a short time become extinct. Disease germs are omnipresent. They permeate the tissues of our bodies and in the intestinal tract swarm by millions. Whether they prevail depends upon natural resistance, or reserve force, and upon the disease soils in the system. The air we breathe is saturated with all sorts of disease germs or their microzyma.

Since baby cannot escape germ invasion, the real problem is how to increase the resistance of the little organism and how to purify it of morbid matter so that disease germs will not find anything to feed on.

Resistance depends largely upon proper nutrition. Diluted, watery milk, contaminated by inorganic minerals, is not a good nutrient; its nutritive value is still more reduced by pasteurizing or boiling. Heating milk or any other proteid food above 1500 F. coagulates the albumen, disorganizes organic compounds, precipitates salts and dissipates the life elements. This reduces the nourishing value and digestibility of the milk.

Nature does not provide the young animal with boiled or
pasteurized milk, and we should not lower food values by such methods.*

* It is now admitted that pasteurization and boiling kills "newly discovered vitamins" which are the "life elements" constantly referred to in my earlier writings.

I do not wish to intimate, however, that scrupulous care and cleanliness should not be exercised in the selection and handling of the milk.

Wherever possible, secure the milk of a single healthy cow that grazes on green pastures or is fed on normal clean food mixtures. Milk from cows kept in stables and fed on brewery and distillery slops and other refuse should not be used.

Every vessel and utensil with which the milk comes in contact must be carefully scoured, submerged in boiling water, drained and kept in a light, airy place.

The nursing bottle, after each feeding, must be taken apart and carefully scrubbed, inside and out, in hot water with an addition of a little soda. It should then be left in pure, cold water, until the next feeding time.

2. When to Feed. Physicians quite generally recommend feedings at stated hours, in fixed quantities.

This is altogether wrong, it establishes at once the stuffing habit, does not permit the development of natural desire and its regulation. The infant very soon becomes accustomed to eating at certain times, whether it really needs the food or not.

Food should not be given until there is an actual demand for it, which will express itself in real hunger. By careful observation and experiment the mother will soon learn to distinguish the ordinary crying of the baby and the desire for food expressed by it. If this practice of feeding only when there is a natural desire for food is strictly followed, the infant will soon establish its own regular feeding times, usually at intervals of about three or four hours in the daytime. The stomach digestion of a feeding of milk will require about three hours, therefore a minimum of that much time should be allowed between feedings after the first few weeks.

If the mother can nurse her baby, it should be put to the breast upon awakening from its first sleep, either before or after bathing and dressing.

The first secretion of the breasts (colostrum) is not really a food, but performs an important function in cleansing the intestinal tract and preparing the digestive system to properly digest and assimilate the milk when it comes, usually about the third day.

3. How to Feed. If artificial feeding must be resorted to, no food at all should be given, except a few teaspoonfuls of water, during the first twenty-four hours after birth. During
the next few days, cow's milk should be given, well diluted—about one-half milk and one-half filtered or boiled water. From week to week the amount of water should be reduced until at the end of the second month the baby takes cow's milk undiluted.

4. Night Feeding. In the nighttime feeding should not be encouraged. During the first four months it is advisable to feed not more than once during the night. After that the child should be weaned from the habit entirely. This will be facilitated by giving a drink of water instead of milk.

5. Amount of Food. Discretion should be observed in determining the amount of food. Do not induce the baby to take as much as possible, rather as little as possible. Its welfare does not depend upon the amount of food consumed, but upon the amount which it can easily digest and assimilate.

When more food is given than the digestive organs can take care of, the entire mass may ferment and sour.

6. Grain Extracts. If undiluted milk proves too rich, grain water may be added. In order to prepare this, take clean grain as it comes from the field, crush it in a hand grain mill or a new coffee mill, take three tablespoonfuls of the crushed grain to one pint of cold water, and boil on the stove for one hour; or in the fireless cooker for two or three hours, in which ease use a little more water at the start. While the gruel is boiling over the fire, add enough water to allow for evaporation and absorption. When thoroughly cooked, strain the gruel through a fine cloth or sieve. Add one tablespoonful, or more if necessary, to each milk feeding.

When baby is constipated, add to the milk, grain extract made from oats, and frequently cool the bowels with cold water. This will cure the most stubborn constipation. If the bowels are too loose, add to the milk, extract made from barley or wheat.

The small particles of hulls in the grain extracts improve digestion and evacuation, in a mechanical manner. They permeate the curds and keep them from coagulating too solidly, thereby facilitating the penetration of digestive juices; they also exert a mild stimulation on the walls of the intestines, thereby increasing the peristalsis of the bowels and evacuation of feces.

7. Baby's Natural Medicines. Fruit juices and scraped raw ripe pear or apple and the pulp of cooked fruits such as prunes or figs without addition of sugar or sweetening of any kind, are baby's finest medicines. They increase the supply of organic salts for blood, nerve and bone building and for purposes of elimination. They are nature's own chologogues, laxatives, tonics and antiseptics. They keep the little body sweet and wholesome. All babies under our care receive fruit juices beginning with the second week.
During the first two months, give one teaspoonful of orange juice, grape fruit juice or prune juice, one hour before or after each nursing. After the second month, gradually increase the amounts of fruit juices and begin to add raw pear or apple scraped with a spoon or dull knife, or the mashed pulp of fully ripened peach or grapes.

8. Weaning the Baby. Nursing infants should be weaned from the breast after the eighth or ninth month. From the sixth or seventh month, both nursing and bottle-fed babies should begin to take some solid food. The best of these to begin with are whole-grain cereals, gruels, raw and cooked fruits and tender vegetables in small amounts. Mealy baked potato is one of the best foods, better than the cereals.

9. Feeding After First Year. After the lapse of the first year, the solid foods are gradually increased and the milk reduced in quantity. Eggs should not be given before the eighteenth month, then soft-boiled or poached. During the second and third year half an egg twice or three times a week is sufficient; after that an egg at a time may be given once or twice a week.

Meat and all other foods prepared from the dead animal carcass are bad enough for adults, but it is inexcusable to give them to tender infants and children.

Dog fanciers, when they sell a valuable canine, usually advise the buyer not to give the animal any meat before the second year, lest it become a victim of distemper; and dogs are naturally meat eaters.

Well informed physicians now generally advise not to give meat to children before the fifth or sixth year. They have learned this much from the nature cure people.

Foods undoubtedly have a powerful influence, not only on the physical body, but also on the mentality and the emotions. These problems will be interesting subjects of investigation for the food chemist and psychologist of the future. In general, we may say that flesh foods are stimulating and feed the passional nature, while fruits and tender vegetables refine and stimulate brain and nerve matter as well as the intellectual, emotional and spiritual activities. Cereals, nuts and pulses build and repair the physical body and supply the body with heat and muscular energy.

The majority of animals adhere strictly to one kind of food, and therefore faithfully exhibit in their mental and emotional characteristics the effects of different food materials. Ferociousness we find personified in the carnivorous bulldog, lion, tiger and panther (that is why soldiers are fed on meat three times a day); gluttony and omnivorous voraciousness in the hog, chicken and hyena; cold-blooded cunning in the fox, and cruelty in the cat. The intelligence of the carnivorous animals displays itself mainly in the cruel cunning with which they stalk their living prey. It resembles in quality the low
intelligence of the human criminal.

Personifications of great physical strength, intelligence, endurance, patience, gentleness, fidelity, affection and self-control, we find among the vegetarian animals. The beaver, the arboreal ape and the elephant are especially noted for their intelligence; deer, antelope and sheep for gentleness; the horse for its almost human intelligence, affection and fidelity; oxen, elephants and camels for their great strength and endurance.

**Meat is detrimental to the child in every way**, physically, mentally and morally. The poisonous acids and alkaloids which it contains clog the capillary circulation, causing anemia, coldness of the extremities and defective elimination through the skin. This results in congestion in the interior organs, high blood pressure in brain and heart, headaches, nervousness, irritability, tendency to fevers, inflammations and catarrhal conditions.

With the meat, the child often absorbs the eggs of worms, tubercular bacilli, and other parasites and disease germs. Certain forms of epilepsy, St. Vitus' dance and hysterical conditions are due to uric acid poisoning and to other pathogenic materials and ptomains contained in flesh foods. Such patients, in times of crises, frequently emit pronounced odors of raw meat or uric acid. Strictly vegetarian diet, combined with other eliminative natural methods of treatment, cures the majority of these cases.

Most of these poisonous acids, alkaloids and ptomains contained in the flesh of dead animals are powerful stimulants. I have frequently noticed that people who have abstained from meat for a long time, when they first partake of it again experience sensations and exhibit symptoms resembling those of alcoholic intoxication.

We have learned that these stimulating extractives of flesh foods chemically closely resemble caffeine, thein and nicotine. The use of one or more of these stimulants invariably creates a craving for the others. This explains why a heavy meat eater is usually a confirmed coffee drinker or inveterate smoker, and vice versa; and why we find it almost impossible to wean people from one of these stimulants as long as they persist in taking the others.

The legumes or pulses—peas, beans and lentils—are close seconds to meat in acid-producing qualities. Eggs contain considerable ready-made uric acid and a great deal of sulfur and phosphorus. These may become dangerous to the organism. For these reasons, meats, legumes and eggs are always danger foods for the child.

Children brought up on such foods will show the effects in nervousness, irritability, lack of self-control, craving for cigarettes and alcoholic stimulants. The most serious aspect of this question lies in the stimulative influence of meat poisons.
on the sex centers. It is a well known fact, verified by close observation, that flesh foods stimulate the sexual passions to a marked degree. This tendency is greatly increased by the use of coffee, tea and alcoholic stimulants in the form of wines, liquors or medicines. If the sensitive nervous organism of a child is overwrought by these powerful irritants, there can be but one result; precocious sexual awakening.

From the third year the child may gradually adopt with slight appropriate modifications, a diet as outlined under Sec. I, No. 10, and Sec. X, No.7.

SECTION XL

Exercises in Infancy

1. Exercises in Infancy. Proper exercise is important from the very beginning of life. A baby will follow its natural instincts for exercise if allowed to do so, by working its arms and legs and writhing its little body in all directions, if not unduly hampered by tight clothing and bandages. A few nude air baths every day will afford excellent opportunity for baby's gymnastic stunts.

After he is a few months old he may be placed on his stomach, when he will exert himself vigorously by trying to raise his head, to turn around, or to raise himself with his arms. He will soon learn to roll over and to creep lie nay now be pulled up gently by his arms and lowered again a number of times in succession.

When three or four months old he may be lifted by one arm or by both arms; by the right arm and left leg, or by the left arm and right leg. When the baby is six or eight months old, he should be strong enough to rise from his back to a sitting position. This may be encouraged by holding down the feet. I have known a number of nature cure babies who at six months of age clung tightly to a stick while being lifted a few feet from the bed. Another good exercise greatly enjoyed by the youngsters is to roll them back and forth on a bed.

The average healthy child will secure ample exercise while learning to walk and run and while playing with simple toys or with other children; but this may be supplemented to good advantage by special exercises devised by the father and mother. Nothing is better for the health and happiness of both parents and children than to join in merry romp and play.

Between two and five years of age the child may be taught more difficult stunts, performed either by himself or with the assistance of the father or mother; but swinging the child high overhead, throwing him up and catching and other dangerous tricks should be avoided. They are risky and have very little effect in developing the body of the child. The best exercise at this age consists in outdoor play and games.
From the sixth year, the question of exercise becomes a more important one, especially since the children are confined for many hours in school rooms. If exercise at this time of life, through play and games and special gymnastics, is neglected, it may affect health, strength and efficiency of the child for life.

Those of good physique and ample strength may gradually take up and practice The exercises for adults outlined in sections XXI, XXII, XXIII, XXIV.

2. **High Chair.** A baby should not be put in a high chair until he is quite well able to hold the spine and head erect, and should never be left in a chair for any length of time. If a baby is forced to maintain a rigid, sitting position for a considerable time, before the bones and muscles are sufficiently developed, this may produce deformity of the spine. Maids and nurses, if not properly supervised, sometimes fasten a baby in a high chair and leave him there to take care of himself for long periods.

3. **Toys.** Since most babies have a habit of putting everything into their mouths, toys must be selected that can do no harm. They should have no paint, no sharp points or corners which might hurt the eyes or mouth, and must be of material which can be easily and thoroughly cleansed. Hairy and woolly playthings are unsafe, being unclean and germ carriers. Objects small enough to be swallowed must never be put within baby's reach. The simpler the playthings the better; a few clothespins, empty spools, or other simple objects are better than expensive toys.

**SECTION XLI**

**Baby's Ailments**

1. **Hernia.** As a result of a weakly or sickly condition of the mother during pregnancy and of faulty prenatal management, many children are born ruptured. So far I have not known a single nature cure baby that was born ruptured. Such defects are due to weakness of the tissues. This results from mineral starvation. The tissue walls contain too much mortar (protein) and not enough building stone (mineral salts). Prevention of hernia, therefore, lies mainly in proper diet of the pregnant mother, but all the rest of the prenatal regimen described in these pages is of great importance in preventing this and other ailments and deformities.

There are three principal points at which rupture or hernia may take place in infancy—at the navel, in the groin, and at the line between the navel and the lower end of the sternum. Other kinds of ruptures are extremely rare.
2. **Umbilical Hernia** This is a protrusion of the intestine at the navel. It is the most common rupture in infancy. Pulling on the cord during childbirth, urging at stool or violent crying may result in rupture. The umbilical ring first expands and this forms a pouch into which one of the folds of the small intestine protrudes.

Treatment: Of primary importance is the diet as outlined herein. The baby must have plenty of fruit juices in order to reinforce the mineral salts in the milk. Cold bathing is very beneficial. The rupture itself should be cleansed several times a day with warm water. This must be followed by a wash with cold water mixed with lemon juice. Gentle, passive exercise, such as raising, lowering and twisting the limbs from side to side, also raising and lowering the body while supporting the shoulders and head, is of especial value.

The rupture must be reduced and kept from protruding by placing over it a large button or other article of similar shape, wrapped in gauze and held in place by broad strips of adhesive plaster. The adhesive tape is fastened over the button crosswise and must be applied in such a manner as to draw the skin from all sides over the rupture. Instead of the button, a compress made of gauze may be laid over the rupture and held in place by one broad adhesive strip. The covering of the rupture must be removed and renewed every day in order to allow cleansing, as before described.

When the child is old enough to exercise by himself, he should be taught special movements of the body and the limbs which develop the muscles of the abdominal region.

3. **Ventral Hernia.** This occurs along the middle line of the body between the navel and the breastbone, sometimes below the navel. The rupture may not be larger than the size of a pea or small marble, and may disappear on pressure. The treatment is the same as that of umbilical hernia.

4. **Inguinal and Scrotal Hernia** occur in infancy or in adult life; sometimes the inguinal canal does not close after the descent of the testes from the abdominal cavity into the scrotum, and the intestine descends through the open canal, thus producing the rupture. These forms of hernia become aggravated by coughing. They can be reduced immediately with gentle manipulation while the patient is lying on his back. This kind of rupture may be distinguished from hydrocele by the fact that in reducing it goes back easily with a gurgling sound. Hydrocele is not affected by coughing. A hernia is opaque to transmitted light; hydrocele, transparent.

These ruptures should be protected with a well-fitting truss. This has to be removed daily for cleansing of the parts. Appropriate exercises, passive and active, together with cooling sitz baths and washes with cold water and lemon juice are the best remedies for these, as well as of other forms of rupture.
5. **Congenital Hernia** occurs in the form of inguinal hernia and has to be treated in the same way. Ruptures of any kind must be reduced and properly supported. Constipation and consequent urging at stool may cause or aggravate any form of hernia and must, therefore, be overcome by the right treatment described under section XXVI, No.1.

6. **Colic.** This is usually caused by indigestion due to overfeeding, improper feeding, or too frequent feeding. The intestines are distended with gas, giving rise to a severe pain. The baby cries sharply, alternately drawing its legs up to the body and kicking them away. One of the quickest means of relief is a small enema of warm water and gentle circular massage of the abdomen from right to left. Food should be withheld until the symptoms have disappeared. The giving of milk or other food may quiet the attack temporarily, but the pain is apt to return with greater intensity. Warm water may be given if the baby will swallow it.

A baby managed in the natural way prenatally and postnatally is not likely to suffer from this ailment. Constipated babies are more prone to it than others.

Colic may also be caused by sudden chilling. In that case a warm bath for five or ten minutes, followed by gentle body massage will bring about a warm reaction.

7. **Convulsions.** These cause a great deal of anxiety to the fond mother. They are always reflex symptoms of some slight or serious internal disturbance due to wrong management. They commonly result from some form of auto-intoxication caused by digestive disturbances, and the resulting systemic or drug poisoning. An inactive condition of the skin, bowels or kidneys will favor auto-intoxication and convulsions. If proper care is taken to keep the system pure, and the organs of elimination in active condition, convulsions will not occur.

The best treatment during an attack is a quick, cold rub all over the body; application of a whole body or trunk pack; gentle soothing magnetic massage, and neurotherapy treatment. These treatments draw the blood into the surface and relieve congestion in the brain and nervous system.

8. **Ailments of Teething.** Many ailments of children are laid to teething, but this is a mistake. Well managed, healthy babies go through the teething period without any trouble whatsoever. This is practically always true of nature cure babies. When, however, the little body is heavily encumbered with hereditary and acquired morbid materials, food poisons and disease taints, the process of teething will not run its natural course and may precipitate any form of disease crisis.

When teething is difficult, it is frequently associated with digestive disturbances. Diarrhea may alternate with constipation and vomiting is of common occurrence. The baby may be restless and fretful. He tries continually to bite on something in order to facilitate the projection of the teeth
through the hardened gums.

No teething lotions or soothing medicines of any kind should be given for the relief of pain in teething. They all contain poisonous sedatives which benumb and paralyze the nerves and have serious after effects upon the system. They usually contain opium in some form, or other narcotic drugs.

The only way to prevent these and other infantile ailments is to keep the little body as nearly normal as possible through the natural treatment described in these pages. If this is closely adhered to, it will prevent, in many cases, the development of even measles and other common eliminative infantile ailments.

During this critical period in the baby's life the diet must be extra light; starchy food should be reduced to a minimum and replaced by raw and cooked fruits and vegetables juices. Cooling sitz baths will help to keep the bowels active and to abate internal fever.

9. Acute Catarrhal Disease. Acute catarrhal diseases of infancy such as croup, cold in the head, acute bronchitis and whooping cough, are different forms of acute elimination through which Nature tries to purify the little body from hereditary and acquired accumulations of morbid matter, systemic poisons and disease taints.

In accordance with this conception of acute diseases, as purifying, healing efforts of Nature, we would not do anything to check or suppress elimination but cooperate with Nature in her purifying, healing efforts. How we do this has been fully explained in other parts of this volume. (Section VIII)

The natural treatment is very much the same in all acute inflammatory ailments. Feeding must be reduced to a minimum. If the baby does not insist upon eating, nothing should be given except water with acid or sub-acid fruit juices, such as lime, lemon, grape fruit and orange. If the temperature does not run high, say not above 100 or 102 deg, frequent ablutions with cold water at intervals of from one to two hours will be sufficient to promote heat radiation and elimination of morbid matter through the skin and other organs of elimination. If the temperature runs' higher, say between 102 and 105 deg, wet packs must be applied, and renewed when they become hot or dry.

The wet packs are of especial value in all kinds of cough; whether it be the ordinary cough, croupy cough or whooping cough. A whole body or trunk pack, with or without a throat pack, will give almost instant relief. In many instances where baby is making the night hideous for the anxious mother, with it's coughing, a well-applied whole body pack, or a combination trunk and throat pack, will relieve the coughing almost instantly, and induce restful sleep.
In serious cases it is always advisable to call in a natural therapist or some other drugless physician, if one can be reached.

The mother should not forget that all acute diseases, after they have once developed, must run their natural course. She must, therefore, not become impatient and lose faith in the natural treatment if it takes a week or more to cure a common cold in the head or an attack of bronchitis, or if it takes from two to eight weeks to cure a case of whooping cough. Serenity, patience and cheerfulness are the primary requisites of the nature cure physician.

PART IV

BABY BOOK

Natural Therapeutics has undoubtedly solved the problem of treating human ailments. All other schools and systems will in time have to adopt the natural way. It is the hub of the healing art; all therapeutic methods radiate from it like spokes from a wheel.

Natural Therapeutics, however, has something better to give than treatment of disease, and that is prevention of disease. If children were brought into this world in the manner ordained by Nature and reared in harmony with the teachings of natural philosophy, disease would soon be a thing of the past. Human beings would then enjoy good health and be as beautiful and perfect in their kind as are animals, which live in the freedom of Nature, guided by instinct and therefore in harmony with the laws of their being.

We must begin, then, with prevention, for prevention is always easier and cheaper, than cure. But where must we begin to study the prevention of disease? Some will say, "At birth, because that is the beginning of life." Not so: that would be too late. The mould is made and the foundation laid for health or disease, for happiness or suffering, for efficiency or deficiency, before the human being in process of creation sees the light of day.

"Then," it may be said, "we must begin with prenatal influence, for the physical, mental, emotional and moral habits of the mother influence powerfully the development of the new life she is carrying." True—but we must start earlier than that. The making of the human being begins with mating and conception. All subsequent development depends upon the right start.

SECTION XXXII

Heredity

1. Importance of Correct Mating. Of primary importance in the sacred rite of procreation, as already intimated, is mating. This should take place only between descendants of the same subrace, or of closely related subraces such as the Indo-Caucasian and Celtic.

If the racial descent of the marriage partners is so far removed that it has produced pronounced differences in racial
characteristic—as in the case of the swarthy Mexican and white skinned Englishwoman, or the dark eyed Magyar and blue-eyed Scandinavian—then procreation becomes miscegenation and degenerates into mongrelization of the offspring. Everywhere in the animal and human kingdoms Nature has set the mark of disapproval on the mongrel. The offspring of miscegenation is doomed to deterioration and extinction unless assimilation of the elements of a lower race by a higher takes place sparingly and gradually.

The law of racial purity may be summed up as follows: When a member of a higher race cohabits with a descendant of a lower race, the offspring of the union loses more or less the characteristics of the higher race and reverts in physical, mental and moral traits to the level of the lower race.

The constructive results of racial purity are evident in Hindus of the higher castes; in that portion of the Jewish race which in mating has faithfully adhered to the Law of Moses, and in the blond and blue-eyed remnants of the Indo-Caucasian and Celtic races in Northern Europe and North America. The destructive results of miscegenation are plainly evident in the mongrelized population of Mexico and everywhere in the half-breed and many kinds of mixed breeds. These usually fall below the physical, mental and moral standards of the parent stock, and almost invariably revert to the customs and habits of the inferior race.

2. Use Heredity. Use heredity deals with the transmission to offspring of acquired physical, mental and moral characteristics of the parents. According to this law as it has been formulated, the chances of the offspring for long life, health, mental efficiency and moral stamina, other conditions being favorable, are better in direct ratio to the advancing age of the parents at the time of conception. While this is contrary to popular opinion, which assumes that younger parents produce more perfect offspring than older ones, the fact of use heredity is proved, both in the animal and human kingdom, by common observation and statistical evidence.

The working of the law is based on the fact that the procreative elements of the parents, or rather the microzyma of those elements, cannot contain the impress of physical, mental and psychical characteristics which at the time of procreation were not developed in the threefold organisms of father and mother.

The age of the father at conception is called the "birth age" of the offspring and determines its birth rank. While the father and previous male ancestors, for reasons hereafter explained, seem to exert greater control over the mental and physical characteristics, the mother furnishes the nutrient soil for physical growth. This does not mean that she exerts no control over the mental and psychical characteristics of the offspring; in addition to her influence through use heredity she has added opportunities through prenatal influence and postnatal training.
According to this law, then, the chances of the offspring for excellent physical, mental and moral development become better as the age of the father at the time of procreation advances beyond thirty five; while the physical condition of the mother for reproductive function is best below thirty five years.

But we must not overlook the fact that too great a discrepancy of age between the man and woman may become the cause of physical and mental incompatibility, of aversion and great unhappiness, especially on the part of the younger woman.

Extensive statistical evidence seems to prove that the birth age of the mother has been of less importance than that of the father. As will be shown in Natural Eugenics, the majority of famous men in all lines or human endeavor had old male ancestors, while the mothers and previous female ancestors were of much younger age at the time of conception.

This may be accounted for by the following reasons:

The man is usually considerably older than the woman at the time of marriage. Men, as a rule, devote much more time and effort to acquiring a scientific, professional or business education than do women. This has been true in the past more than it will be in the future. Thrown early into the competitive struggle of life men generally have had to make greater mental and physical effort than have women.

These points are of considerable importance because it has been proved that it is not inherited brain mass and mental capacity, but strenuous and persistent effort that intensifies use heredity. The earlier this begins and the longer it continues before procreation takes place, the better the chances of the offspring for physical, mental and moral capacity.

The reproductivity of the mother has usually ceased at thirty-five. Though she be capable of childbearing a few years longer, usually conception has been avoided after that age. Men under favorable conditions remain reproductive to advanced age. Some of the world's greatest men descended from fathers over sixty years old.

That intellectual and creative capacity has followed the male line of descent rather than the female line, is indicated by the fact that the high intellectual capacity of many eminent men has skipped their daughters to reappear in male descendants. This may be partly accounted for by the fact that the daughters in their limited spheres of activity have not had the opportunity to unfold inherent intellectual capacity to any conspicuous degree.

There has been a tendency in some quarters to criticize the general entrance of women into professional and commercial life and to dilate upon the adverse influence this will have
upon womanly characteristics and family life.

In the light of the knowledge we possess upon the subject of use heredity, it is safe to say that any such problematical drawbacks will be far outweighed by the general postponement of the marriage age. This will insure not only better physical fitness but also higher intellectual development and greater moral stamina on both sides of parentage.

The tremendous benefits which this increased hereditary endowment will confer upon future generations cannot be overestimated. Greater intellectual and economic equality between the sexes will emancipate woman from degrading sexual subservience. Under the old order, sex appeal was too often her only stock in trade by which to attract and hold the male and thus to secure a living. Economic independence will insure greater consideration and higher esteem for the woman on the part of the man. It will go a long ways toward solving the problem of birth control in a natural way, by leaving it more largely to the judgment of the mother.

We find the law of use heredity according to birth age verified in the intelligence and moral development or obliquity of races, nations and tribes all over the earth—The lower the average birth age of a race or nation, the lower, other things being equal, the intellectual and moral development The greatest development and efficiency is found among those nations where marriage is delayed to a later age through custom, economic necessity, professional or military training.

The following quotation from "Control of Heredity", by Casper Lavater Redfield, is of interest in this connection:

"In general it may be said that wherever there are no restraints upon the sexual propensities, as with the Digger Indians, the Fuegians, the Andamanese, the Wauraus of the Guianas, the Bushmen and the tribes along the Gabbon river, there we find reproduction taking place at the earliest possible age, and the lowest grade of intelligence. Where we find some special circumstances or customs that delay the age at which reproduction takes place, as with the Patagonians, the North American Indian and the Polynesians, there we find considerably higher grade of intelligence.

"Where we find the custom of marrying late in life, as was customary with the Greeks and the Romans, there we find a very high grade of intelligence. And where we find a fortuitous succession of very late births, there we find the very great men of the world's history.

"In other words, the longer the time in which the individuals have in which to use, develop and strengthen their brains before reproduction begins, the greater and more powerful are the brains of their descendants."

In Volume IV of this Series I shall quote elaborate and
highly interesting statistics from Redfield, which reveal the
effects of the various birth ages on physical, mental and moral
characteristics. I shall confine myself, for the present, to the
statement that, with few exceptions, the great artists,
scientists, philosophers, statesmen and philanthropists were
born from fathers whose ages ranged from forty to sixty-five
years at the time of the procreation of their famous offspring.

The existence of these laws and principles as facts in nature
is very evident in the training of racehorses and of other
animals along certain lines of proficiency.

3. Pernicious Heredity. The effects of deteriorating and
destructive heredity prenatal and congenital influences have
been traced and commented upon in so many different ways
that I do not believe it necessary to enter deeply into this
phase of the subject. Various authors have filled entire
volumes with the unsavory family histories of the descendants
of the Jutes, Ishmaels and other drunkards, prostitutes,
degenerates and criminals, which prove positively the
transmission of morbid and pernicious traits through
successive generations. It has been proved statistically beyond
the shadow of a doubt that youthful delinquency, pauperism
and criminality are the aftermath of immature marriages.

The laws of use heredity and prenatal influence, like all
other natural laws and principles, manifest along opposite
lines of expression. It remains for us to determine whether we
shall align ourselves with their destructive or constructive
activities. The effects upon ourselves and our offspring will
show accordingly.

If I succeed in arousing the consciousness of prospective
fathers and mothers to the glorious privileges and enormous
responsibilities which these laws of nature confer upon them,
then my labor will not have been in vain and I shall feel
deeper gratified.

SECTION XXXIII

1. The Creative Alchemy of Love and Affection

Procreation—as is the case with everything else pertaining
to the constituents and functions of the human entity—takes
place on three planes of being, the material (physical and
spiritual), the mental and the psychical planes. Which of these
elements shall predominate in the offspring depends upon the
mixture and adjustment of qualities in the triune makeup of
the mating couple. In order to fulfill the law and to draw the
divine blessing upon themselves and the fruit of their union
the partners in the procreative function must be united by the
bonds of love, or at least by the ties of true affection.
The source of creative genius is love and wisdom, and the essence of intelligence and power is sincerity and goodness. Without these, intelligence degenerates into selfish cunning, power into self-destructive brute force. The spring cannot rise higher than its source; its water cannot be pure and wholesome when contaminated by impure admixtures from filthy surroundings.

It is not generally known that use heredity pertains to intellectual and psychical qualities, as well as to the physical material. Animalism breeds nothing but selfish animalism. The vampire who craves and absorbs the love of its victims and robs them of vital energy, without being capable of feeling or bestowing affection, is the child of a discordant union—of brute animalism on the part of the man, of secret aversion and hatred, usually, on the part of the woman. These bestial and degrading tendencies on the one side, and unrequited love craving on the other, breed sex perversion, and propagate the harpies who delight in the seductive power of superficial beauty, while gloating over the weakness and ruin of their victims.

True love and affection, paired with intelligence and goodness; liberate the creative elements necessary to the production of perfect offspring.

The finer qualities of mind and soul open the fountains of life on the higher planes, liberate and harmonize the male and female procreative fluids, and charge them with the purest and most potent intellectual, spiritual and psychical elements.

The divine fire of creative genius burns only in the love aura of truly mated couples. It is true that these are rare under our artificial, unrighteous social institutions, and that accounts for the rarity of complete manhood and womanhood.

Perfect offspring, endowed with beauty and power of body, mind and soul, destined to shed through life a radiance of health, happiness and helpfulness—to love and be loved—issues only from the union of love and affection with intelligence and goodness.

"Love lieth at the foundation" (of all that is). "Love is passion, enthusiasm, affection, heat, fire, soul—God."

To the extent that love enters into the holy rite, to that extent its attributes will be absorbed in the threefold organism of the woman and become active in the child building in her womb. While she loves her man more than ever, her most passionate affection is centered in the new being in process of development. On it she bestows the purest and best in her food and drink, in her thoughts, emotions and secret desires. Fear, worry, anxiety, jealousy and hatred are strangers to her soul; these are the emanations of the lower spheres—she lives in heaven.

Somebody endowed with deep insight into these matters has
said:

"Whatever male and female shall truly will for, hopefully pray for and earnestly yearn for, when love pure and holy is the nuptive ascendant, in form, passional, affectional, divine and volitional, that prayer shall be granted, and the boon be given—but the prayer must precede."

What are the direct effects of the marital rite upon the participants? If the sex attraction operates on the physical material plane only, if lust instead of love presides at the matrimonial feast, then temporary gratification of erotic craving will be followed inevitably by monotony, satiety, gradual revulsion and aversion, culminating in a morbid craving for change and variety. The partners in carnal self-indulgence are intuitively aware of these tendencies to marital unfaithfulness, and, therefore, easily dominated by distrust and jealousy.

The procreative function is attended by complete satisfaction, buoyancy of body and mind and lasting happiness only when sex attraction operates on the higher and highest planes of being, as well as on the lower, when desire and impulse are operative on both sides. Thus only will the generative function fulfill its sacred purpose and confer the highest possible benefits upon parents and offspring.

The woman, being the more highly sensitized, must be responsive to the call of holy passion. To force unwilling compliance will ruin the woman, kill her love and curse her offspring. Balzac says: "He who begins with his wife by a rape is a lost man." It is impossible for a wife to love unless she is won, not forced to compliance.

2. Sexual Intercourse During Pregnancy. Sexual intercourse should be considered the most sacred function of the human entity. From the highest and best viewpoint it should be exercised only for the propagation of offspring. However, considering the present stage of ethical and moral development, temperate indulgence may not be wholly condemned. Excessive intercourse is always weakening and harmful to both participants. We must remember that the sex fluid is the carrier of the life force. It is that which constitutes strength, resistance to disease, initiative and genius. During abstinence from intercourse the sex fluids with their creative energy are absorbed through the inguinal glands into the organism and increase physical, mental, moral and spiritual capacity and energy.

Set rules for frequency of intercourse cannot be given. This must depend entirely upon individual conditions. One safe rule is that after indulgence there should be no feeling of satiety, weakness and exhaustion. The more frequent the indulgence the stronger will grow the power of habit and of passion and the greater will become the abnormal craving. It is the same with all other appetite and passions. The more frequently they are indulged, the stronger they grow, until
they attain complete control and develop into destructive habit

A free and confidential understanding in regard to these matters between those who contemplate matrimony would go far to prevent marital misery. A great deal of unhappiness arises from the fact that mates in the matrimonial union often labor under misapprehensions concerning the attitude of each toward the sex relation, and are prevented by excessive sensitiveness and delicacy from frankly discussing it. (For further discussion of this subject, see page 390, Volume I.)

There is no problem of married life that needs more thorough mutual consideration and understanding than this one. Lack of it accounts for a great deal of "incompatibility," loss of love, revulsion, hatred, and the final tragedy in the divorce court.

Among animals, no female allows intercourse after conception. In this respect as in many others, man has sunk below the natural standards of the animals. No greater crime can be committed against the woman and the unborn life.

It is a sad commentary on our system of education, scholastic as well as religious, that our young people are not instructed before and after marriage in these all important laws of Nature. To do this should be the province of the priest who unites them in marriage, or of the family physician, if the parents have failed in their duty.

It is well known (notwithstanding the denials of medical skeptics) that the unborn infant may be "marked" by transitory impressions, especially by strong emotions; that even insignificant parental characteristics are reproduced in the offspring. Is it any wonder, then, that the most powerful of human emotions should leave its impress on the growing brain and sex centers of the fetus, causing abnormal and precocious sex consciousness?

All too often is sex perversion born and bred in bone and flesh, before the child sees the light of day. The mother cannot be blamed for this "slaughter of the innocents"; she has not been instructed on the subject. Though she intuitively senses the horror of it, she submits, in order to maintain her hold upon the man—and many a life is thus cursed before it is born. The fault lies primarily with those of the medical profession who teach our young men that the free indulgence of sexual passion is not only legitimate, but a necessity to manly vigor.

This dictum of pseudo-science is almost universally concurred in by spiritual guardians. No greater lie was ever promulgated from the blackest abyss of Hades. If our young men were taught that greater happiness is to be attained by the exchange of tender affection than by the indulgence of the coarser animal appetites, that the creative forces thus preserved develop and strengthen their own finest capacities
of body, mind or soul, they would wisely and chivalrously protect mother and child, at the same time conserving their own physical and moral integrity.

In no other way is it possible to call forth the deepest gratitude and unfailing esteem of a true woman. Many a man whom we have thus advised has become a lifelong friend in consequence.

3. Limitation of Offspring. I believe that the unlimited production of offspring, encouraged in some quarters for swelling the ranks of religious bodies or for increasing tax paying and cannon-fodder material, is a misfortune, both to the family and to society. Limitation of offspring, in accordance with the means and circumstances of the parents, is not only justified but should be encouraged. In any case, the production of offspring entails great responsibility upon the parents and if they cannot properly comply with the needs and rights of their children, they fail in their responsibility and duty.

Any method, however, which interrupts intercourse or prevents conception in an artificial way, is absolutely to be condemned, because this has very harmful and positively destructive effects upon the physical, nervous and mental organism of those who thus try to cheat nature by the suppression of a natural process. In our professional work we frequently meet the victims of such pernicious practices. The ordinary contrivances for prevention make of intercourse something akin to masturbation. This is also true of intercourse without orgasm which is strongly advocated under various guises. The use of poisonous antiseptics and germ killers in warm water douches is not essential for prevention, and is highly injurious. These chemicals have a tendency to poison the sexual organs and to produce in time atrophy, many kinds of female disorders, and tumors. Undoubtedly the greater number of so called female troubles and malignant tumors in later life are caused by curetments, antiseptic douches and the use of poisonous drugs, for producing abortion. The only legitimate methods of birth control are abstinence or common cleanliness.

There is nothing more conducive to the physical, mental and spiritual health and development of a woman than childbearing and child rearing in harmony with Nature's laws, as outlined in these volumes. Under favorable conditions it is not a thing to be dreaded, but to be looked upon as the greatest of blessings and opportunities in the life of a woman. Natural philosophy and practice takes these problems of progeneration, childbearing and childrearing out of the domain of uncertainty and haphazard management with its dire consequences, and makes eugenics the most exact of all sciences and the sublimest and most enjoyable of all the arts.

4. Determination of Sex. Numerous theories have been advanced concerning this interesting subject. Many attempts have been made to wrest from Nature the secret of sex
determination and numerous more or less ingenious methods have been recommended for sex control.

I know of one method only which seems to have a rational basis and which has proved of practical value. Observations seem to prove that the right ovary liberates male ova only, while the left ovary discharges female ova. The two ovaries discharge ova only at alternate menstruations.

With this data at hand, it is possible to determine the sex of a child after one birth has taken place. Suppose the first child was a boy. By consulting our pregnancy table (page 377) we can determine when the last menstrual discharge took place. This menstruation liberated a male ovum; the next menstruation would liberate a female ovum, the next a male, etc.

Thus, using the last menstruation period before the last conception as a fixed point, it would be possible, figuring from period to period, to determine the sex nature of the ovum to be discharged at each following menstrual period. Account is taken of all regular periods during the time menstruation is suspended in pregnancy. Thus, conception may be timed in such a way as to impregnate at will a male or female ovum.

This solves in a simple, rational manner another of Nature's riddles, namely, the reason for the practically equal division of the sexes.

SECTION XXXIV

Prenatal Influence

There exists just as much diversity of opinion among scientists concerning the reality of prenatal influence as about race heredity, use heredity, disease heredity and many other mooted problems of science and philosophy, which we shall study in Vol. IV of this series. In the following I shall present and examine impartially the various theories and opinions concerning prenatal influence; then we shall be better prepared to draw our own conclusions.

1. Medical Science Denies Prenatal Influence. Medical men, as usual cocksure of the correctness of their theories and hypotheses based on the "latest discoveries", deny and ridicule the possibility of prenatal influence, and relegate it to the rubbish heap of popular superstitions. They base their judgment on the fact that no nerves pass from the body of the mother through the umbilical cord into the growing fetus in the placenta, which forms the soft protecting nest of the new life within the womb. They claim that since no direct nerve connection exists between the two, mental and emotional vibrations cannot be transmitted from the brain of the mother to the brain and nervous organism of the fetus.
Are there no other means of communication between the mind of the mother and the brain of the unborn!

In the volume dealing with Eugenics we shall learn how universal intelligence and creative will become individual intelligence and personal will.

Cosmic vibrations do not flow into the gray matter of the human brain over coarse physical nerve tracts. They come over the psychical wireless which connects the human soul with the world Soul, the individual intelligence with the universal or cosmic intelligence the human will with the divine will.

Since, as proved by modern brain and nerve anatomy, immaterial cosmic intelligence and "power to will" fashion the brain of the mother into physical material centers for the expression of human intellectual faculties, capacities and powers, why cannot these cosmic vibrations act in like manner over the psychic wireless through the soul and mind of the mother on the brain and nervous system of the fetal organism?*

These epoch making discoveries and revelations of modern brain anatomy are explained in Vol. IV of this Series, *Natural Eugenics—Man Building on the Physical, Mental and Moral Planes.*

Why should the wireless, which transmits impulses of intuitive intelligence from the great source of all intelligence and creative energy into the soul of the mother, cease to operate at that point, and fail to transmit its message to the brain and nervous system of the fetus which is most intimately related and connected with the organism of the mother?

What about the phenomena of hypnotism? Absolute control of the subject's mind, through the intelligence and will of the hypnotist does not depend upon the existence of an umbilical cord and physical nerve connection between the two. The hypnotist, by silent command, may call his subject from a distance, far beyond the reach of his voice.

People telepathically attuned may communicate in like manner, spontaneously, or by conscious intent. Why then should we doubt the possibility of vibratory correspondence between the mental and emotional conditions of the mother and the plastic nervous organism in process of development within her womb?

If a complexity of sound can impress itself permanently upon the wax cylinder of a phonograph, or what is still more marvelous, if the photographic rays of passing scenes can be fixed and retained in the picture film, why should it be impossible for the mental and emotional vibrations of the mother to impress and modulate the molecular and cellular constituents of the fetal brain and nervous organism?
I have compared this creative power of the mother mind to the process of electrotyping. As the particles of metal in suspension in the fluid adhere to the spoon that is to be coated with silver, so the atoms and molecules in the gray matter of the brain of the fetus group themselves in harmony with the thought forms and emotional vibrations of the mind and soul of the mother. While this mental and psychical electrotyping takes place automatically, the mother's brain and nerve molding power can be greatly strengthened and intensified by the conscious and voluntary operation of the psychical wireless that establishes vibratory oneness between her and the human entity in process of development within her own body.

Thus it is revealed how a brain prenatally refined, organized and fashioned may endow the nascent individuality with certain aptitudes and talents along established paths of cerebration. There surely will be less resistance along such lines of physical, mental and moral endeavor than along other lines not prenatally influenced and molded. Therefore I strongly advise mothers, pregnant with new life holding marvelous possibilities for good or evil, not to be influenced by the superficial reasoning of materialistic science, but to follow the sacred intuition and impulse of their own creative genius in this, the most holy function of their being. Every normally constituted mother is intuitively aware of this wonderful power, and is willing and anxious to exercise it when her consciousness has been aroused to the great possibilities and responsibilities which the divine privilege of motherhood confers upon her.

It is natural for us to admire a great artist who portrays the human form, true to life, on the painted canvas, or who fashions it from inanimate stone, metal or marble; how much more grand and godlike is the creative power of truly mated parents whose privilege it is to bring into the world, and to fashion according to their highest ideals, a human being endowed with life and intelligence, with the infinite possibilities of a new center of creative activity.

Yet many mothers, totally ignorant of their divine creative privileges and possibilities, victims of physically and morally degrading marriage relations, and often filled with secret aversion or open hatred for their marital companions, pass unwillingly through pregnancy and not infrequently seek to destroy the new life. When the unfortunate victim of such marital incompatibility, conceived in passion and developing under the worst possible influences of mental and emotional discord, comes to arouse the maternal instincts of affection and devotion, then fear, anxiety and worry, like a continual nightmare, haunt the unhappy mind of the mother and impress their discordant vibrations upon the sensitive films of infant consciousness.

Compare this condition of fear, apprehension and gloom in the mind and soul of an unhappy and unwilling mother, with the joyful and ecstatic state of mind of a mother conscious of
the creative power of her intelligent will, who, from the time of mating and procreation, with accurate prescience prepares the most favorable conditions, astrologically, prenatally and postnatally for the finest development of the physical, mental and moral characteristics of the future world citizen.

The loftiest exaltation of a creative genius working in dead clay and cold marble cannot approach the ecstasy of a mother who has acquired a knowledge of the great laws which make possible the development of a perfect human being,-the embryo of a master, an angel, a being destined to be godlike in its faculties, capacities and powers!

In place of fear and anguish of soul, what joy to the mother who knows that it lies within her power to prevent disease and degeneracy in her offspring; that the development of the child depends solely upon her own intelligent effort! Nothing is left to accident. Child bearing becomes an exact science, the most beautiful and inspiring of all arts and professions. Under such conditions motherhood, instead of being the greatest of hazards and hardships, becomes a divine privilege and the highest achievement of human existence and endeavor. It falls short only of the creative work of the great Universal Intelligence whose instrument of creation is the mother.

2. An Example from History. Let us consider the oft-quoted example of Napoleon Bonaparte. His mother, Lutitia Bonaparte, while pregnant with the future military genius, accompanied her husband on a military expedition, sharing with him the hardships and excitement of camp life, and the marches and battles of a military campaign. If there be nothing in prenatal influence, is it not singular that Napoleon should have become one of the greatest military geniuses of all ages, while not one of his many brothers ever exhibited enough military ability to make an efficient corporal? What was it that favored or determined the birth of the great military prodigy under these circumstances? The ancestors of Napoleon's father were not professional soldiers, nor was the father especially interested in military matters before the conception of his gifted offspring.

The dominant influences, therefore, must have operated through the singular occupation and surroundings of the mother during this particular pregnancy.

Many similar striking examples have been cited in works on prenatal influence. I myself might add many convincing proofs from an extensive experience in medical practice; but time and space do not permit. Contributory evidence may be secured from many excellent works dealing with this vital problem in human life. I may be permitted to say that use heredity and prenatal influence are distinctly manifest in the physical and mental characteristics of our three children who were born at intervals of seven and five years. Each one of them clearly mirrors in his or her physical, mental and emotional peculiarities the predominant mental tendencies, occupation and surroundings of the parents during the
respective prenatal periods. Similar manifestations of prenatal influence may be observed in almost any family.

3. Birthmarks. Medical men of late deny also the possibility of "marking" the offspring by sudden fear or shock on the part of the mother during pregnancy. Incidents of this kind, however, are of such common occurrence that it is a waste of time to refute these flippant denials.

There are good reasons for believing that such marking is more likely to occur during the periods when the menstrual flow should take place, but is suspended.

It may be argued that to mention the possibility of marking to a pregnant woman will greatly increase the probability of electrotyping violent emotions upon her offspring; in other words, that the fear of the thing will help to materialize it. This may be true to a certain extent, but we must remember that sudden shock through fear or disgust may cause the mischief anyway, whether or not the expectant mother is aware of the possibility. Understanding a danger and being prepared for it seems the best protection. The pregnant woman should study carefully section XXX, dealing with mental and emotional causes of nervous diseases, and should learn to relax to any sudden surprise and thus neutralize unpleasant and fear arousing impressions. Self-control is the royal remedy and the key to mastership.

4. Physical Influence. Now that we have studied some of the more important hereditary mental and psychical prenatal and postnatal influences, let us see how the physical condition of the mother's organism influences the brain and nerve matter of the fetus in its last stages of development, and after birth.

Materialistic science teaches that brain matter exudes thoughts and feelings, as the liver excretes bile, or the stomach pepsin. Natural science proves that mind is superior to matter, that the new born ego, by the power of intelligent volition, must fashion in the gray matter of the brain the molecular groupings or centers for the expression of intellectual and emotional activities, such as language, music, numbers, scientific and philosophic speculation.

This means that active cerebration and brain molding do not begin until after birth. But it stands to reason that the work of the nascent intelligence may be greatly facilitated or impeded by the physical condition of the brain. It is reasonable to assume that intellectual and emotional vibrations will more easily shape the gray matter of the brain into new configurations when it has been prenatally refined, organized and developed along certain lines of cerebration by use heredity and by constructive prenatal influences.

There exists a remarkable similarity between the brain molding and memory building activities of the intelligent ego and the making of phonographic records and moving picture
films. Lifelike impressions of sounds and passing scenes can be made upon the phonographic and photographic mediums only when wax and film are in a highly refined and plastic condition. When impure of substance and coarse of texture they, are not sensitive and plastic enough to register and retain the subtle and highly complex vibrations of sounds and passing scenes. In order to receive and register a great variety and complexity of sounds, the wax on the phonograph cylinder must possess a certain degree of refinement, softness and plasticity. If it is too hard and coarse it registers the loud and coarse sounds only. Such a record cylinder, exposed to a beautiful symphony executed by a great orchestra, would register and reproduce only the shrill cries of the trumpet, the rattle of the snare drum and the booming of the big horns and bass drums. The softer sounds of string, wood and wind instruments and finer shadings of tone and rhythm would be lost. With increasing refinement and plasticity, more subtle and delicate sound vibrations will be retained and reproduced.

In like manner the sensitive gray matter of the cortex of the brain must be in a pure and plastic condition in order to receive and register the impressions and impulses coming through the sensory organs, the psychic intuition and the intellectual and emotional activities of the mind. Anything in the way of physical impurity or foreign matter that tends to clog the brain, or to feed it with waste and morbid materials, or with corroding poisons, will lessen the atomic and molecular motility of brain and nerve matter, and will interfere with, or impede, the groupings and subtle transformations involved in the fashioning of brain centers through mental and emotional influences.

If the nutrient blood which feeds the brain substance of the fetus be saturated with CO₂, the benumbing, paralyzing carbon-dioxide, with clogging uric acid or the destructive acids of phosphorus and sulfur, the gray matter cannot, respond to the subtle and complex impressions and impulses from without and within.

The purity or impurity of the plastic matrix of the cortex depends upon the materials absorbed from food and drink. If these are so constituted as to create in the system excessive amounts of clogging and corroding substances, then these food and drink poisons will have a benumbing and deteriorating effect upon the sensitive gray matter of the brain, as well as upon the coarser tissues in the joints, muscles and vital organs. There is a rheumatism of the mind as well as of the joints.

A brain asphyxiated and clogged with pathogenic materials cannot be alert and active; it is too dull and lazy to think; it would much rather sleep than work; it is incapable of doing its best when its tiny blood and lymph vessels are obstructed with waste and morbid deposits which prevent the oxygenation and drainage of its delicately organized cellular tissues.
This, of course, is true postnatally as well as prenatally. A brain originally capable of the highest and finest achievements of the human mind may become utterly worthless, and may degenerate into idiocy through food, drink and drug poisoning.

Medical men tell mothers they need not worry over prenatal feeding, because the placenta, the vascular bag which forms the nest of the new life, acts as a filter which purifies the blood before it reaches the fetus. Common sense and every day experience tell another story. Even the best in the blood of many mothers is bad enough to serve as food for the new life.

The placenta does not filter out of the blood of the mother all food, disease and drug poisons. This is proved by the wretched condition of many infants, suffering from malnutrition, anemia and rachitis, after delivery. If the vital fluids of the mother are deficient in the mineral elements, or in other important nutritive substances, how can they deliver them to the fetus?

Occurrences like the following, quite common in our institutional practice, prove positively that the placenta is not a perfect filter for systemic poisons and for disease taints circulating in the blood of the mother.

One of the most pitiable cases of eczema in a little child less than one year old we traced to the fact that the mother, during her first year of marriage, had traveled with her husband through Eastern European and Asiatic countries, and during her pregnancy had been vaccinated five times while passing through localities where smallpox was prevalent. Both she and her husband had always enjoyed perfect health. The family record was excellent as far as traceable; still the body of the infant soon after birth, was covered with open bleeding sores, presenting a revolting sight. We could find no explanation for this strange phenomenon other than the many vaccinations during pregnancy. These had contaminated the blood of the mother, and through her the body of the fetus, with a filthy scrofulous taint.

The baby suffered terribly. For many months it slept but little, because of the excruciating pains. The eczematous eruptions were of a very stubborn nature; they broke forth again and again. Finally, however, after eighteen months of natural treatment, we succeeded in purifying the little body of the horrible infection. The child is now a little over three years old, in perfect health, and during the last twelve months has shown no signs of the morbid taint.

Under another section I shall describe the influence of food upon character and sex life.

To recapitulate: Purity, plasticity and motility of the highly refined and sensitive materials which make up the gray matter of the brain depend upon pure food, plenty of fresh air and exercise, and upon all other natural methods of living.
1. Conception takes place whenever the male spermatozoon joins the female ovum (egg) within the woman's womb. Normally the female organism liberates from its ovaries but one ovum each month, usually during menstruation, while the male discharges millions of spermatozoa at each orgasm.

Conception does not always follow copulation. The ovum remains in the womb and is capable of impregnation for about five days after menstruation. The spermatozoon on entering the womb may meet an ovum which has been discharged at a previous menstruation, or it may remain alive in the womb for a number of days and finally come in contact with a newly discharged ovum at the following menstruation.

The spermatozoon retains its ability to impregnate the ovum for from ten to fifteen days after its discharge into the womb. When the male and female germs merge into one another, conception or impregnation takes place. As soon as this has happened, the impregnated ovum becomes attached to the inner lining or mucous membrane of the womb and begins its new life as an embryo. The period comprising the time from the impregnation of the ovum until the beginning of labor or childbirth is called pregnancy.

The table of pregnancy on page 377 indicates the probable date of normal termination of a pregnancy, calculated from the last menstruation.

2. Exercise During Pregnancy. Unfortunately a great many expectant mothers labor under the idea that they must rest and be relieved from work and exercise. This of course is a great mistake. Light housework is good exercise. There is nothing more harmful during pregnancy than nursing "that tired feeling" by lounging idly about the house and coddling one's real or imaginary aches and troubles.

Of great benefit to the pregnant woman are all outdoor sports such as tennis, golf and other games which require vigorous exercise without straining or overworking the body. The great benefit of walking and other outdoor exercises, aside from their general invigorating effects, lies in the strengthening of the abdominal muscles and ligaments, which at delivery will greatly facilitate expulsion of the fetus.

The walk should be brisk and rhythmical, body erect, head thrown back, chest forward; the breathing at the same time should be deep and regular. These walks should be continued as long as time and endurance permit. Nothing, of course,
must be pushed to the point of exhaustion. One good long walk every day is necessary; two are better.

We all understand the necessity for a plentiful supply of oxygen under ordinary conditions, and especially in time of illness. During pregnancy the demand for oxygen, as well as for mineral salts, is doubled or trebled on account of the needs of the rapidly developing organism in the womb of the mother.

These extra demands for oxygen and ozone must be supplied by systematic deep breathing, cold bathing, outdoor walks, etc. If circumstances do not permit the taking of outdoor exercise, deep breathing should be practiced as often as feasible, at the open window.

Next in importance among gymnastic exercises is the internal massage described under section XXI, No.16.

Those exercises are especially valuable which bring into play the abdominal muscles and the muscles and ligaments of the genital organs.

3. Clothing. Clothing and the manner of wearing it profoundly influences the normal or abnormal development of the fetus, the health of the mother, labor and delivery.

At no time should the waistline be constricted by a corset or even by the ordinary skirt band. All clothing should be as loose and light as possible—one-piece under and outer garments, with the weight suspended from the shoulders, are best. If skirts are worn they should be fastened to skeleton waists of some thin cotton material. The close, heavy texture of the material from which the corset or so called "reform waist" is made is injurious because it interferes with skin elimination.

Even the slightest constriction of the waist line interferes with the free circulation and the normal blood supply to the abdominal organs, which is of especial importance in pregnancy; it also hinders the free expansion and movement of the uterus during the various stages of pregnancy.

Within the waistline are located a dozen or more important vital organs of the body. Any sort of constriction compresses these organs and pushes them out of their normal position. While this is extremely injurious to the body of a woman under ordinary conditions, it is doubly so to the pregnant mother and to the rapidly growing fetus. Undoubtedly many deformities and monstrosities are produced by unnatural constriction of the blood vessels and vital organs in the abdomen and pelvis of the pregnant woman.

If due attention is paid to the foregoing influences, labor and delivery will be brief and easy. This we have proved in hundreds of cases which have come under our management. The reason why women of civilized countries spend many
hours and sometimes days in dreadful agony of childbirth while those of primitive or savage races, as we call them, produce their young easily and painlessly as the animals do, is that primitive women live more simple and natural lives, while "civilized" mothers violate practically every law of Nature in their daily habits of living.

Civilization unfortunately stands in many respects for that which is artificial, unnatural and therefore productive of disease and suffering in all domains of life, not only as regards physical health, but social and political health as well.

SECTION XXXVI

Danger Signs During Pregnancy

1. *Dropical Swelling*. Swelling of the limbs and distention of the veins of the legs during pregnancy may be caused by a tendency towards varicosity, intensified by obstruction of the circulation due to the enlarged uterus. Such a condition requires, aside from the natural regimen, careful and competent treatment.

   Swelling of the limbs or other parts of the body may also be caused by incipient or advanced Bright's disease. The urine should be examined from time to time, especially if there is a swelling of the feet and ankles, or if there are dropical symptoms in other parts of the body.

   Such dangerous conditions are usually brought about through the excessive intake of starchy and protein foods which overwork the liver and kidneys and cause pathogenic dogging of the capillary circulation. This may result in uremia attended by violent and sometimes fatal Convulsions.

   2. *Uremia* is the result of retention in the system of waste materials and poisons that should be eliminated through the kidneys and skin. Medical treatment for such conditions, aside from the administration of stimulating drags, consists in hot bathing with the idea of opening the pores of the skin.

   We understand that all hot water treatment gives only temporary relief and is followed by greater enervation and inactivity of the skin. The best water treatment for systemic poisoning of any kind consists in the application of wet packs followed by cold ablutions as described in section XV.

   The addition to the packs, dry friction rubs, air bath, good massage and neurotherapy treatment will aid in restoring the normal activity of skin, bowels and kidneys.

   Whenever the urine contains sugar or albumen, fasting, alternating with raw food diet, is indicated. Suitable regimens are outlined in sections X, XI.
The giving of heavy food to the mother with the idea of increasing the flow of milk is all-wrong. We have found in all cases that the diet outlined in section X will produce a more copious flow of rich milk than lie "nourishing" meat diet. The best remedy for a scanty flow of milk is slow and thorough mastication of a few spoonfuls of raw crushed wheat every day.

3. Morning Sickness. One of the common disorders experienced during pregnancy is that known as Morning Sickness. One suffering from this ailment, though following a natural diet, should sip a cup of hot postum while remaining in bed. If this does not have the desired effect and if the patient has not been accustomed to drinking coffee, half a cup of black coffee with a few drops of lemon juice will quiet the irritated nerves. It is necessary after taking the hot drink to remain in bed for at least thirty minutes. It is understood that this is only an emergency measure. If continued, it will lose its good effect and work injury.

SECTION XXXVII

Labor and Delivery

At about forty weeks, exactly nine solar months, from the period of conception the fetus reaches full maturity, and labor begins. Labor is divided into three stages. During the first stage the neck of the womb becomes slowly and gradually distended and the orifice of the womb opens widely. When this has taken place, the fetal membranes burst and the amniotic liquid surrounding the fetus escapes.

During the second stage the fetus emerges from the womb.

After expulsion of the fetus, the placenta is expelled from the uterine cavity. This constitutes the third stage of labor.

The first stage usually begins with more or less radiating pains in the abdomen, accompanied by dull pain in the small of the back and a drawing pain in the limbs. Sometimes women with the first baby feel these pains weeks in advance of the actual commencement of labor. At first they occur at long intervals and are of short duration, but gradually become more prolonged and more frequent. The pains are due to a cramp-like contraction of the muscular apparatus of the uterus forcing its contents downward.

Under this pressure from above, the neck and mouth of the uterus distend to their limits, and the walls become thinner and thinner. First the inner, then the outer orifice of the neck of the womb opens and the fetal membranes protrude and finally rupture, allowing the amniotic fluid to escape. Shortly after this the part of the fetus nearest the orifice, normally the
head, makes its appearance. At the present time the average
duration of the first stage of labor is six hours, but it may last
twenty-four hours or longer, depending upon the plasticity
and elasticity of the bony structures of mother and infant, the
rigidity of the cervix, and the vigor or lack of vigor of the
muscular apparatus of the uterus.

While the foregoing is true of the average delivery under
ordinary ways of living, we find that after the enforcement of
a natural regimen of living during and, better still, before
pregnancy, the entire period of labor and delivery does not
cover more than half an hour, or at the utmost from one to
two hours. Even the disadvantages of slight build and
smallness of pelvis can be overcome by the natural regimen
outlined in section X. When our youngest child was born, the
mother gave the first sign of pain at about midnight. I rose
from bed instantly, but had not time to finish clothing when
the membranes broke. Within twenty minutes after the
commencement of labor the infant was resting in my hands.

The wife of a prominent lawyer in a western city had
experienced three difficult deliveries. Each time surgical
instruments had to be used and she had suffered untold
agonies lasting from 24 to 36 hours. When she became
pregnant the fourth time the most prominent physicians in her
home city assured husband and wife that it was not safe for
her to go through another delivery, that the womb was in
worse condition than ever before therefore they recommended
surgical removal. For conscientious reasons, however, the
husband and wife did not follow the advice of the doctors, but
decided to try natural methods of treatment.

The lady placed herself under our care during the fifth
month of pregnancy. From that time on she followed strictly
the natural regimen of living and received daily the usual
hydropathic and manipulative treatments. This was continued
until a few weeks before delivery. In this case the baby was
born within an hour from the first contraction, and the mother
of the patient, who was in an adjoining room, had not heard a
sound. Many similar experiences refute the idea that it is
unsafe and injurious for pregnant women to undergo the
ordinary methods of natural treatment, such as hydropathic
sprays, sitz baths, massage, Swedish movement and other
forms of manipulation.

1. Preparation for Delivery. The diet during the last week
before the beginning of labor should be very light, consisting
mostly of fruits and vegetables. From the commencement of
labor no food at all should be given, until at least twenty-four
hours after delivery; a three-day fast is better.

In addition to a competent physician, a nurse or midwife
should be engaged. If a good neurotherapist, who has had
sufficient experience in obstetrical work, can be procured, he
should be preferred, because he can assist delivery and make
it much easier by manipulative treatment.
The nurse will make the necessary preparations and provide the various supplies needed in labor. With the first sign of approaching labor, the physician in charge should be summoned. A rectal enema of one pint or more of warm salt water (See. XVIII, No.4) should be administered. The woman should be given a vigorous cold rub and her genitals thoroughly cleansed. She may then remain on her feet and walk about, comfortably dressed, until actual labor commences.

2. **No Anesthetics.** The attending physician should not be impatient to hasten delivery with drugs or instruments. The use of anesthetics should be avoided insofar as this is possible. They should be employed only when absolutely necessary—that is, when excessive pain must be allayed or when surgical delivery is unavoidable.

3. **Breaking of Water Bag.** When the bag of water is about ready to break, the patient is placed in bed. Premature discharge of the amniotic fluid must be guarded against. An escape of the liquid at an early stage means difficult and prolonged labor, commonly known as "dry labor". Usually the membranes burst when the orifice is fully dilated. A large sponge is held in readiness to catch the out-flowing liquid.

3 a. **Umbilical Cord.** When the infant has been delivered, the umbilical cord should not be severed at once. Plenty of time should be allowed for the blood to transfuse itself from the body of the mother to that of the child. This is important. If the connection is severed too soon, the child begins life in an anemic condition.

The newborn baby usually greets the world with a lusty cry. It should be placed on its right side with its face turned away from the mother, care being taken that the cord is not stretched tight. As soon as the cord stops pulsating, plenty of time being allowed for blood transfusion, it is tied about two inches away from the baby's abdomen and cut a little above the ligature. The baby is now wrapped in a warm blanket and put in its crib.

4. **After Delivery.** Immediately after the baby is born, the nurse or attending physician gently compresses the abdomen and womb of the mother, kneading and rubbing it occasionally in order to secure complete contraction and thus prevent hemorrhage. After delivery the mother enjoys a period of rest and recuperation which usually lasts for about half an hour.

5. **Afterbirth.** Meanwhile the placenta becomes detached, and when the pains set in again a few contractions usually suffice to expel it with all the membranes.

The attending physician must make sure that none of it is left in the body, since this might result in putrefaction of the remains and blood poisoning. The woman's genitals should be washed with clean sterilized water.
The exhausted woman should now enjoy a deep, wholesome sleep and awaken from it in a few hours refreshed and strengthened.

In the foregoing I have not gone into the details of obstetrics and of technical management because this must be left to a competent obstetrician. I have called attention only to those points which are of special importance from the viewpoint of Natural Therapeutics and to the differences in treatment between the conventional and natural methods.

6. The Lying-In Period. The lying-in period varies from five to twelve days, according to the constitution of the mother and the care that she has taken during pregnancy. The greatest danger of the lying-in period is puerperal sepsis or blood poisoning. This condition is the result of infection occurring during labor, or it may result from the retention of parts of the placenta.

The only way to prevent this is by observing the most scrupulous cleanliness during the entire process of childbirth and during the lying-in period. When blood poisoning has developed it must be treated the same as all other acute inflammatory diseases (see section IX).

7. Care of the Newborn. The child should begin to breathe immediately after the cord is cut. If it fails to do this, the physician should lift the baby by its feet to facilitate the escape of mucous from the trachea and throat. If necessary the mucous must be removed from the throat by the insertion of the little finger, or by means of a tiny stick covered with gauze.

Breathing may be accelerated effectively by a few sharp taps on shoulders and buttocks. If this fails to bring the desired result, artificial respiration must be resorted to at once. The attendant grasps the child by its shoulders, its head resting between his palms and the two index fingers being hooked under the child's armpits. It is now swung between the physician's legs and lifted high above his head so as to be turned upside down. This is repeated from fifteen to twenty times, after which it is placed in a basin containing a few inches of warm water. Its body should then be rubbed briskly with cold water.

Father Kneipp used to take the newborn babe by the nape of the neck and the feet and submerge it quickly in cold water. This, a few times repeated, is probably the quickest way of resuscitating an asphyxiated baby.

In order to soften the cheesy deposit which frequently covers the body of the newborn, it is well to rub the skin with warm olive oil. After the greasy covering has sufficiently softened it may be removed with bits of gauze. This is followed by a cleansing bath with warm water and castile soap.
After the warm cleansing bath, the little body should be quickly rubbed down with cold water, wrapped in a soft, warm blanket and laid away to sleep until it wakens of its own accord. A normal baby should sleep for about twelve hours, and must not be disturbed to force food on it before it is ready to take it.

8. Bathing. From the first day, the baby must have a morning and evening bath. This consists, as before described, in a quick, cleansing bath of warm water and castile soap, followed immediately by a brisk cold rub. In the course of a few weeks the baby can be placed, for the cleansing bath, in a small bathtub containing a few inches of warm water. Immediately after the cleansing bath the warm water is replaced by cold water. This is taken up in the hollow of the hand and briskly applied to the little body. In this fashion the child, within a few months time, will enjoy its cold rub just as much as an adult. I have seen several such nature cure babies, but a few months old, object most vigorously to a warm bath. The cold rub is the best preventive of chilling; but care must be taken that the temperature of the room where the bath is given is not below 70 deg.

The olive oil bath or rub, often recommended for premature babies or infants suffering from malnutrition, is very injurious, because it occludes the pores of the skin and prevents the elimination of poisonous gases and other morbid materials from the body. The skin is not an organ of digestion. Olive oil, like all other foods, must enter the body through the alimentary canal where, under the action of digestive ferments, it is broken down into its component elements which are then assimilated through the intestinal membranes. Oil absorbed through the skin is not digested, and it circulates in the body as foreign matter which in this state cannot be assimilated and utilized in the system.

9. Powdering after the bath is fully as injurious as the rubbing with oils or massage creams. Powders and creams tend to clog the pores, and most of them contain poisonous antiseptics which lower the vitality of the skin and prevent or suppress elimination in the form of skin eruptions, eczemas, etc. For chafing use nothing but cold water. In case the chafing should become unusually severe and painful, through neglect by the caretaker, a soothing and healing lotion composed of one part lemon juice to two parts olive oil, may be applied a few times, until the irritation is under control.

10. Air Baths. Next to cold water, there is nothing that will invigorate baby's skin and nervous system as will the air and sun bath. If the season will not allow the outdoor air bath, the baby should be allowed to lie nude several times a day, for thirty minutes or more, in a warm, well ventilated and sunny room.

11. Constipation. Glycerin and suppositories should never be used; neither laxatives nor cathartics. Oat extract and cooling sitz baths will produce natural movements.
12. **Diarrhea** is a form of morbid elimination, and must never be suppressed by drugs. If it is habitual, bailey or wheat extract prepared in the same manner as oat extract, is a good remedy. If the diarrhea is persistent and of a violent nature, no food at all must be given, except water with dilute acid fruit juices, until the purging ceases. Even then plenty of time must be allowed for the rebuilding of the sloughed intestinal membranes.

13. **Bandages.** Until the umbilical cord dries up and falls off, it is necessary to cover the navel with a gauze compress dipped in olive oil. This is held in place by an abdominal bandage made of soft cotton material. These strips should not be hemmed, merely torn or cut. They should be drawn just snugly enough to hold the compress in place, but not tightly enough to interfere with circulation. The, navel must be cleansed and the compress renewed twice each day. After the umbilical cord has dropped off we no longer apply the abdominal bandage. This is contrary to common usage, but is the best practice. The abdominal bandage overheats the body and interferes with the free movement of the diaphragm and the circulation of the blood.

14. **Clothing.** The clothing of the infant should be loose and light and as simple as possible. Freedom of movement is very important; binding or pressure upon any part cannot help but interfere with the circulation, and otherwise produce injurious results. The clothes should be short, in order to allow the feet and legs free play. Light weight, porous cotton materials are best for both under and outer garments. A lightweight wool petticoat may be worn when absolutely necessary to provide sufficient protection for the baby. Cotton hose and bootees may be used, but under no circumstances should such articles be of wool, because it prevents free elimination from the skin. The baby's head should not be covered out of doors, except in severe weather. At no time should a veil be placed over the face, as it will cause the infant to reabsorb the poisonous exhalations from its own lungs. All clothing should be changed each day. No garment should be starched—such a practice is not only useless but harmful.

15. **Diapers** must be provided in sufficient number to allow thorough cleansing and drying. The wet diapers should be scalded in hot water and very thoroughly rinsed in several waters afterwards. They should then be dried in the open air and sunshine. Soiled diapers must be well washed and boiled. Washing powders, soda, ammonia and other chemicals should never be used. They have an extremely irritating effect upon the delicate skin of a baby. In order to save labor and to facilitate the cleansing of the diapers, small squares of clean old linen or muslin rags, or pieces of absorbent gauze, may be placed inside. These inserts will absorb all or most of the bowel movement and may then be burned. If the skin is irritated or chafed, the parts should be sponged off with clean cold water at each change, paying special attention to cleansing of the genitals. Oils or powders must not be used to soothe the sore places, because they clog the pores and
Interfere with natural elimination.

16. A wet nurse is to be preferred to artificial feeding. She should be thoroughly healthy, not over thirty years of age, of equitable temper, not excitable or nervous and her diet should be that prescribed for the mother.

17. Care of the Nipples. They should be thoroughly cleansed before and after nursing; not with carbolic acid, but with water and dilute lemon juice. The lemon juice tends also to harden the nipples. Treatment of the nipples may begin before the birth of the child.

18. Care of the Eyes. The baby's eyes, whether awake or asleep, should always be shielded from strong light, either sun or artificial, and from dust and wind. The eyes should be washed with cold water after every cleansing bath. If they show any tendency to weakness or disease, slight vibratory massage over the closed eyelids should be given after the cold eye bath.

19. Care of the Mouth. A healthy baby's mouth needs no cleaning before the arrival of teeth. As a matter of fact, the teeth of a perfectly healthy adult would not need cleaning any more than do those of an animal living in the freedom of nature. The saliva is a sterilizing fluid, under normal living, intended by Nature to keep the mouth clean and healthy. Cleansing of the mouth of an infant with the finger or with a cloth may injure its delicate membranes. If the mouth must be washed, in case of disease, a swab made by twisting a piece of sterilized absorbent cotton on the end of a smooth stick should be used. The swab should be dipped in warm boiled water, and the interior of the mouth washed thoroughly, the cotton then being burned.

20. Care of the Ears. The external ear should be cleansed with a soft rag or swab as before described. Never use a hard instrument inside the ear.

21. Care of the Nose. A baby's nose should be cleansed as a part of the daily toilet, in the same way as the ears. A swab may be made by twisting a, piece of gauze to a cone. As soon as the child becomes old enough, it should be taught to sniff up cold water through the nostrils and the nasal passages. This is the best way to keep the nasal membranes in a clean, healthy condition.

22. Care of the Genital Organs. The genital organs of both sexes must be kept scrupulously clean with as little handling as possible. The foreskin of the penis of the male baby should be drawn back at bathing time and the organ thoroughly cleansed, always finishing with cold water.

23. Phimosis. The treatment of phimosis is fully described under Sec. XXVIII, No.1.

24. How to Lift the Baby. The best way to lift a young
baby is to slip the left hand under the back beneath the shoulder, spreading out the fingers in such a way as to support the neck and head. Then lift the feet and legs with the right hand. Never lift an infant without first supporting the spine.

When a baby has grown strong enough to hold up its head and has gained considerable strength in the muscles of the back and neck, he may be lifted by grasping him with outspread fingers under the armpits; the body must be held firmly so that the entire strain does not come on the shoulders. A baby should never be lifted by the arms. This may dislocate the shoulder joints.

SECTION XXXVIII

Prenatal Feeding

1. Effects of Diet During Pregnancy. The problem of infant nutrition begins before birth. Prenatal feeding determines the physical start in life. On it depends not only the condition of the mother's health during pregnancy, but also the size and weight of the fetus, pliability of the bony structures, ease or difficulty of delivery, and the quality of the mother's milk.

The fleshier and heavier the newborn infant, the prouder and happier are the parents and the doctor. Yet, excessive size and weight of the child constitute the most prominent cause of difficult and painful childbirth and frequent necessity for instrumental delivery.

The biblical saying, "In sorrow thou shalt bring forth children"; has led many to believe that woman's dreadful suffering is a necessity, God ordained; but is not man's ignorance, rather than the cruelty of an avenging God, to blame?

This latter view is confirmed by the fact that other mammalia literally cast their young, without pain or difficulty; and the labor pains of primitive mothers are insignificant, their delivery presenting little more difficulty than that of the lower animals. A squaw on the Western Plains stops a few hours by the wayside to deliver her papoose and then resumes her journey as though nothing had happened.

Women among the European peasantry, who wear no corsets, live on black bread and vegetables, and have plenty of exercise in the fields and in the home to the last day of pregnancy, have their babies without help of midwife or physician and resume their usual routine of work within a few days after delivery.

Thousands of mothers who have adopted natural ways of
living have learned to dispense with anesthetics and the surgeon's instruments; they now bring forth their offspring without excessive pain.

2. Results of Faulty Diet. It is significant that the offspring of the lower animals, at birth, consist of little more than skin and bones, while the newborn human is often abnormally large and fat. This is especially true of babies born of weak and anemic mothers. As before stated, excessive size and weight of the infant is not a matter for congratulation, but is a pathological condition. It indicates fatty degeneration of the fetus, due to the anemic watery condition of the blood of the mother, and the cause of this hydremia of mother and child lies in the faulty dietetic habits of the former.

The ordinary diet of American women consists almost entirely of meat, fish, fowl, potatoes, white bread, pastry, coffee, tea and refined white sugar. The few vegetable, which enter into the daily dietary are first deprived of their all important organic salts by faulty cooking; fruits are looked upon as luxuries and frequently are regarded as harmful.

The anemic, watery condition of the blood of mother and child is not due to a lack of starchy, protein and fatty materials in food and blood, but to a deficiency of organic mineral elements. Neither is the anemic condition, as the regular school of medicine assumes, caused by lack of iron. Any ordinary food mixture, as well as the blood and milk of anemic mothers, usually contains a sufficient amount of iron. The actual cause of the anemia is a deficiency of other mineral elements.

As I have explained in Volume III of this Series, carbonic acid poisoning and the resulting sluggishness of the surface circulation, coldness of the extremities and congestion of the inner organs is not caused so much by a lack of the oxygen-carrying iron as by a deficiency of the carbonic acid neutralizing and eliminating sodium and magnesium.

If the blood is deficient in lime, phosphates, silicon and fluorine, rachitic conditions, softening of the bones, deformed spines and legs, and decay of the teeth, are inevitable results.

It is an easy matter to supply the daily needs of the organism for proteids, starches, fats and sugars; the difficulty lies in supplying a sufficient amount of the organic mineral elements.

The deficiency of sodium in human blood, Dr. Lahmann proved in the following table of comparative blood analyses. In a hundred parts of ash he found in the

</table>
The percentages of lime and of other positive mineral elements in the human blood are also much lower than in the blood of cows, oxen and sheep.

While the blood of cattle and sheep raised on pasture is very uniform in composition, hardly any two samples of human blood are alike. It is for this reason that Dr. Lahmann adopted cow's milk instead of human milk as the standard elementary food combination.

In the following table, he compares the percentages of minerals in the ash of cow's milk with the percentages of mineral elements in the ash of various other food materials.

A daily dietary consisting largely of meats, eggs, white bread, potatoes, peas and beans, though excessively rich in proteids, fats and starches, will, on account of its deficiency in sodium, lime and magnesium, inevitably result in carbonic acid poisoning, anemia, rachitis, premature decay of the teeth and a multitude of other acute and chronic ailments.

If, however, the daily dietary contains a liberal amount of green vegetables and fruits, a normal food mixture resembling that of cow's milk can easily be obtained. It must be remembered that fruits and vegetables are not only rich in the most important mineral salts, but that they are relatively poor in proteids and carbohydrates.

For this reason fruits and vegetables facilitate the establishment of an equilibrium between proteids and carbohydrates on the one hand and organic mineral salts on the other.

3. Excessive Fat Formation. We can now understand why the ordinary faulty diet of pregnant mothers causes anemia, softening of the bones, sluggish circulation, carbonic acid poisoning and fatty degeneration in mother and offspring.

Lack of sodium causes excessive accumulation of carbonic acid, and oxygen starvation. This results in defective
oxidation of food and waste materials; in other words, in fat formation.

Defective draft prevents the complete consumption of coal, and chokes the furnace with the products of imperfect combustion. Similarly, lack of oxygen in the tissues (due to carbonic acid poisoning) causes an incomplete combustion of food materials and waste products, resulting in fat formation and in the generation of poisonous byproducts.

Lack of sodium also prevents the neutralization and elimination of uric and other acids and ptomaines (pathogenic matter) which accumulate in the tissues, block the circulation and assist in the smothering of the vital processes.

In order to eliminate these pathogenic materials, there arises an abnormal craving for water—"the anemic thirst"—which is closely related to the thirst of fever patients and of diabetics. Excessive water drinking is encouraged by the popular "flushing" fad.

To make things worse, the anemic, for reasons before stated, usually suffers from weak heart action and sluggish circulation. This means defective elimination of water through the skin and kidneys, resulting in a watery (dropsical) condition of the tissues and fatty degeneration.

Not all anemic, carbonic-acid-poisoned mothers, however, develop a tendency to obesity. On the contrary, under certain constitutional conditions, they may become exceedingly lean, like the anemic, carbonic-acid-poisoned consumptive. Briefly stated, sluggish heart action and weak kidneys favor retention of carbonic acid and water in the tissues and thus make for fatty degeneration. Good circulation and normal activity of the kidneys may keep the system free from excess of water and carbonic acid, but excessive proteids in the diet may result in sulfuric and phosphoric acid poisoning. These destructive acids break down the tissues, rob them of their mineral constituents, and thus cause excessive loss of flesh and fat.

In both types of dysemia the blood of the pregnant mother is overloaded with poisonous gases, waste matter and the debris of broken-down tissues. The oxygen supply to the fetus is therefore very much impeded and we find that both fleshy and lean mothers produce babies of abnormal size and weight, ranging from eight to twelve pounds, while the normal weight of the newborn should not be more than six pounds.

4. Advantages of Natural Regimen. We know of many instances where mothers, after having given birth to heavy, fleshy babies, in subsequent births have reduced the weight of the new born to normal, and the pain of delivery to a minimum, by the adoption of a natural diet, plenty of exercise in the fresh air and systematic deep breathing.
The effects of a natural regimen are manifested in various other ways. The bony and muscular structures of mother and child are much more pliable and elastic, making parturition and delivery much easier. Pure blood, normal nutrition and abdominal exercises, walking and special gymnastics, greatly strengthen the abdominal and uterine muscles, thus facilitating expulsion of the fetus.

The morning cold rub, systematic deep breathing and general exercises, every day outdoor walks and right mental and emotional attitude are all of paramount importance in the regimen of pregnancy.

The Regimen for Wholesome Living, section I, is admirably adapted for all the needs of the pregnant mother.

SECTION XXXIX

Postnatal Feeding

Thanks to the educational influence of nature cure propaganda, a decided change for the better in baby feeding has taken place during the past ten years. Up to that time the "top cream mixture" was universally recommended by allopathic physicians and given to babies by trained nurses.

While in the meantime many physicians and nurses have adopted more natural methods, the "top cream mixture" is still too common and must be entirely abolished in order to safeguard the health of our little ones.

In the February, 1909, issue of the Nature Cure Magazine, I commented upon this subject as follows:

1. Bottle-fed Babies. Our food analyses disclose the interesting fact that the elementary composition of the ash of the milk of an animal is about the same as the composition of the ash of its body.

They also show that good cow's milk when normal comes closer to the requirements of the infant body than does inferior human milk.

Our tables of food analyses show that chemically the composition of cow's milk and of human milk is very much the same. Human milk contains a little less proteid and a little more sugar than cow's milk, and the latter is much richer in organic salts than the former. There is much more of the all-important sodium in cow's milk than in human milk and about twice as much calcium (lime) and iron (table p.100). This explains why rachitis is so common among babies, while never found among calves.

As we have learned, the elimination of poisonous acids
from the body depends on sodium. The building of the bony structures depends on lime; the oxygenation of the blood, on iron.

Many years of practical experience in the care of babies has convinced me that milk fresh from a healthy cow is greatly to be preferred, as nourishment for infants, to the impoverished milk of scrofulous mothers.* In this connection it is significant that one-half of all "civilized" mothers, thanks to unnatural food and drink, vaccination and poisonous drugs, are incapacitated for nursing their offspring.

* This may not be true in the future if our milk cows continue to be regularly subjected to tuberculin tests.

To one who has studied the comparative analyses of cow's milk and human milk, it is incomprehensible why the former, when given to infants, should be diluted and spoiled by large quantities of water, salt, soda and inorganic mineral lime (in the form of lime water).

This procedure, however, is still frequently recommended by physicians of the regular school. Undoubtedly, the great frequency of anemic and rachitic diseases, the darkening of the iris, appearance of scurf rim, and the signs of catarrhal conditions in stomach and bowels are caused by such unnatural feeding.

The following extracts are taken from an article entitled "Bottle-fed Babies", in the Ladies' Home Journal. It was written by Dr. Emelyn Lincoln Coolidge, of the Babies' hospital, New York. Thousands of mothers, on account of the high standing and excellent reputation of this family journal, undoubtedly have followed, without question or misgiving, the advice presented.

The formulas given below are for the average healthy baby, and are called "cream" or "top milk" mixtures.

"Food for the first month. With a spoon, or a tiny dipper which comes for this purpose, carefully skim off the top six ounces from a quart bottle of milk; to this add twenty-four ounces of water which has been boiled and cooled, and in which has been dissolved three teaspoonfuls of granulated or six of milk sugar; next add a pinch of bicarbonate of soda and a small pinch of salt; mix this all thoroughly, and pour enough for each feeding into ten separate bottle& Then cork the bottles family with cotton and either Pasteurize the milk or stand it on the ice.

"For the second month. Skim off six ounces of cream, then pour off three ounces of milk; add twenty-four ounces of water and the same amount of sugar, salt and soda as above; mix and bottle.

"For the third and fourth months. Cream, six ounces; milk, six Ounces; water, twelve ounces; barley or oatmeal gruel, twelve ounces; sugar, salt and soda as usual, etc.

**Plain Milk Formulas**

"Pour the entire quart of bottled milk out into a clean pitcher and then back into the bottle several times, thus thoroughly mixing the milk; then take:
"For the first month. Six ounces of milk, twenty-four ounces of barley-water, half a tablespoonful of granulated or one of milk sugar, a pinch of bicarbonate of soda; mix all well together and pour the proper number of ounces into separate bottles, and either Pasteurize or place on ice.

"For the second month. Nine ounces of milk, twenty-one ounces of barley-water, one tablespoonful of sugar, and a pinch of soda."

Physicians would never think of giving such advice as this, if they were acquainted with natural dietetics founded on exact and complete analyses made by food chemists of the nature cure school.

I have already called attention to the fact that food chemistry, whether practiced in allopathic colleges, in great sanitariums or by vegetarian food reformers, deals with proteids, starches, fats and sugars only, and leaves entirely out of consideration the all important mineral elements or organic salts of potassium, sodium, iron, lime and magnesium.*

*This was true at the time this article was published in the Nature Cure Magazine.)

On these five positive mineral salts, as we have shown, depend all the important vital functions of the human organism, while proteids, starches, fats and sugars serve only as building and fuel material.

The digestion of the proteid and carbohydrate foods, as well as the elimination of the waste matter resulting there from, depends upon the positive organic mineral salts.

Study carefully these recipes for baby feeding, taken from the Ladies' Home Journal, and compare the mixtures with the analyses of cow's milk and human milk in the accompanying tables.

Let us consider the "top milk" mixture, prescribed for the first month. The cream rising to the top is almost pure fat. The all-important mineral elements plus the nourishing milk sugar and proteids remain in the skimmed milk, which is looked upon as worthless and fed to the pigs.

Our food analyses (see tables in Volume III, Cook Book) show that the ordinary brands of flour are almost devoid of mineral elements. Furthermore, one teaspoonful of barley to one pint of hot water does not mean much in food values. Where in these six ounces of cream (fat) and twenty-four ounces of barley water is baby to get the necessary amount of sugar for fuel material, of proteid for tissue-building, of lime for bone-building, of iron for oxygen-carrying, and of sodium, magnesium and potassium for the processes of elimination?

It seems that these deficiencies are intended to be overcome by baking soda, mineral table salt and the lime water, so generally prescribed by physicians. Many times I have demonstrated that inorganic mineral salts, with the possible exception of a little table salt, should not enter the animal or human organism, that these salts must first be organized,
made alive in the plant or animal cell, before they are wholesome food for animals or human beings. I have shown that, taken habitually in the mineral form, these salts accumulate in the human body, act as irritants and poisons and reveal their presence in the iris of the eye.

I fail to understand why the tender and sensitive organism of the newborn infant should be encumbered with inorganic minerals while cow's milk contains them in ideal form, made alive first in the grasses and grains, then still more highly organized and magnetized in the body of the animal.

It is bad enough to give mineral sodium, lime and table salt to an adult, but it is little short of criminal to give them to babies under the guise of foods and medicines.

The cream mixtures are readily digested, because there is not much to digest. The fact that infants thus fed cry for food continually is good evidence that their needs are not satisfied. Babies fed with this sort of slop grow fat for a while. The watery food inevitably produces fatty degeneration. This for a season swamps the little body with unhealthy fat. But the first crisis which happens along often takes away not only the unnatural fat, but the baby also.

The artificial mixtures contain entirely too much water in proportion to nourishing elements. The resulting malnutrition and the constant irritation caused by the inorganic minerals result in chronic diarrhea or constipation.

**The Right Way**

The best food for the newborn and growing infant is undoubtedly the mother's milk, provided that she is herself in fairly good health. Unfortunately, many mothers are unable to nurse their offspring, and if a healthy wet nurse cannot be secured, other food must be provided.

The best substitute for human milk, without question, is cow's milk, fresh, pure and undiluted, as it comes from the animal.

"Why", indignantly exclaims the trained nurse, when we give these instructions, "undiluted cow's milk is altogether too rich, it is indigestible for baby; if the milk is not boiled or pasteurized, germs and bacilli will surely create infectious diseases".

To this we answer: Our analyses show that the difference in composition between cow's milk and human milk is not enough to affect the infant. The danger lies not so much in overfeeding on "rich" cow's milk as in underfeeding on watery milk and cereal dilutions, and in poisoning the little body with inorganic minerals.

As regards germ infection and the necessity for pasteurizing the milk, the menace to health and life is greater through
malnutrition than through germs and bacteria. Germs we cannot escape, not even if we were surrounded on all sides by walls of air-purifying and antiseptic materials.*

*Since the foregoing was written we have learned that low vitality and morbid soil will develop perfectly normal microzyma into so called disease germs.

One of the foremost French bacteriologists claims that in the mouths of infants shortly after birth he has found almost every disease bacillus known to medical science.

William Osler; M.D., to whom the English language is indebted for the verb "to oslerize," says in The Principals and Practice of Medicine on page 151, in the chapter on Diphtheria:

"The presence of the Klebs-Loeffler bacillus is regarded by bacteriologists as the sole criterion of true diphtheria, and as this organism may be associated with all grades of throat affections, from a simple catarrh to a sloughing, gangrenous process, it is evident that in many instances there will be a striking discrepancy between the clinical and the bacteriological diagnosis."

In the first part of this sentence he states that bacteriologists regard as the sole criterion for the diagnosis of diphtheria the Kiebs-Loeffler, or diphtheria, bacillus; in the last part of the sentence he admits that this bacillus is found in even slight catarrhal conditions, and he might add that it is found just as frequently in the mouth and throat of healthy infants and adults. This is a good example of "orthodox" scientific reasoning.

If germs and bacilli of themselves could destroy health and life, the human race would in a short time become extinct. Disease germs are omnipresent. They permeate the tissues of our bodies and in the intestinal tract swarm by millions. Whether they prevail depends upon natural resistance, or reserve force, and upon the disease soils in the system. The air we breathe is saturated with all sorts of disease germs or their microzyma.

Since baby cannot escape germ invasion, the real problem is how to increase the resistance of the little organism and how to purify it of morbid matter so that disease germs will not find anything to feed on.

Resistance depends largely upon proper nutrition. Diluted, watery milk, contaminated by inorganic minerals, is not a good nutrient; its nutritive value is still more reduced by pasteurizing or boiling. Heating milk or any other proteid food above 1500 F. coagulates the albumen, disorganizes organic compounds, precipitates salts and dissipates the life elements. This reduces the nourishing value and digestibility of the milk.

Nature does not provide the young animal with boiled or
pasteurized milk, and we should not lower food values by such methods.*

* It is now admitted that pasteurization and boiling kills "newly discovered vitamins" which are the "life elements" constantly referred to in my earlier writings.

I do not wish to intimate, however, that scrupulous care and cleanliness should not be exercised in the selection and handling of the milk.

Wherever possible, secure the milk of a single healthy cow that grazes on green pastures or is fed on normal clean food mixtures. Milk from cows kept in stables and fed on brewery and distillery slops and other refuse should not be used.

Every vessel and utensil with which the milk comes in contact must be carefully scoured, submerged in boiling water, drained and kept in a light, airy place.

The nursing bottle, after each feeding, must be taken apart and carefully scrubbed, inside and out, in hot water with an addition of a little soda. It should then be left in pure, cold water, until the next feeding time.

2. When to Feed. Physicians quite generally recommend feedings at stated hours, in fixed quantities.

This is altogether wrong, it establishes at once the stuffing habit, does not permit the development of natural desire and its regulation. The infant very soon becomes accustomed to eating at certain times, whether it really needs the food or not.

Food should not be given until there is an actual demand for it, which will express itself in real hunger. By careful observation and experiment the mother will soon learn to distinguish the ordinary crying of the baby and the desire for food expressed by it. If this practice of feeding only when there is a natural desire for food is strictly followed, the infant will soon establish its own regular feeding times, usually at intervals of about three or four hours in the daytime. The stomach digestion of a feeding of milk will require about three hours, therefore a minimum of that much time should be allowed between feedings after the first few weeks.

If the mother can nurse her baby, it should be put to the breast upon awakening from its first sleep, either before or after bathing and dressing.

The first secretion of the breasts (colostrum) is not really a food, but performs an important function in cleansing the intestinal tract and preparing the digestive system to properly digest and assimilate the milk when it comes, usually about the third day.

3. How to Feed. If artificial feeding must be resorted to, no food at all should be given, except a few teaspoonfuls of water, during the first twenty-four hours after birth. During
the next few days, cow's milk should be given, well diluted—about one-half milk and one-half filtered or boiled water. From week to week the amount of water should be reduced until at the end of the second month the baby takes cow's milk undiluted.

4. Night Feeding. In the nighttime feeding should not be encouraged. During the first four months it is advisable to feed not more than once during the night. After that the child should be weaned from the habit entirely. This will be facilitated by giving a drink of water instead of milk.

5. Amount of Food. Discretion should be observed in determining the amount of food. Do not induce the baby to take as much as possible, rather as little as possible. Its welfare does not depend upon the amount of food consumed, but upon the amount which it can easily digest and assimilate.

When more food is given than the digestive organs can take care of, the entire mass may ferment and sour.

6. Grain Extracts. If undiluted milk proves too rich, grain water may be added. In order to prepare this, take clean grain as it comes from the field, crush it in a hand grain mill or a new coffee mill, take three tablespoonfuls of the crushed grain to one pint of cold water, and boil on the stove for one hour; or in the fireless cooker for two or three hours, in which ease use a little more water at the start. While the gruel is boiling over the fire, add enough water to allow for evaporation and absorption. When thoroughly cooked, strain the gruel through a fine cloth or sieve. Add one tablespoonful, or more if necessary, to each milk feeding.

When baby is constipated, add to the milk, grain extract made from oats, and frequently cool the bowels with cold water. This will cure the most stubborn constipation. If the bowels are too loose, add to the milk, extract made from barley or wheat.

The small particles of hulls in the grain extracts improve digestion and evacuation, in a mechanical manner. They permeate the curds and keep them from coagulating too solidly, thereby facilitating the penetration of digestive juices; they also exert a mild stimulation on the walls of the intestines, thereby increasing the peristalsis of the bowels and evacuation of feces.

7. Baby's Natural Medicines. Fruit juices and scraped raw ripe pear or apple and the pulp of cooked fruits such as prunes or figs without addition of sugar or sweetening of any kind, are baby's finest medicines. They increase the supply of organic salts for blood, nerve and bone building and for purposes of elimination. They are nature's own chologogues, laxatives, tonics and antiseptics. They keep the little body sweet and wholesome. All babies under our care receive fruit juices beginning with the second week.
During the first two months, give one teaspoonful of orange juice, grape fruit juice or prune juice, one hour before or after each nursing. After the second month, gradually increase the amounts of fruit juices and begin to add raw pear or apple scraped with a spoon or dull knife, or the mashed pulp of fully ripened peach or grapes.

8. Weaning the Baby. Nursing infants should be weaned from the breast after the eighth or ninth month. From the sixth or seventh month, both nursing and bottle-fed babies should begin to take some solid food. The best of these to begin with are whole-grain cereals, gruels, raw and cooked fruits and tender vegetables in small amounts. Mealy baked potato is one of the best foods, better than the cereals.

9. Feeding After First Year. After the lapse of the first year, the solid foods are gradually increased and the milk reduced in quantity. Eggs should not be given before the eighteenth month, then soft-boiled or poached. During the second and third year half an egg twice or three times a week is sufficient; after that an egg at a time may be given once or twice a week.

Meat and all other foods prepared from the dead animal carcass are bad enough for adults, but it is inexcusable to give them to tender infants and children.

Dog fanciers, when they sell a valuable canine, usually advise the buyer not to give the animal any meat before the second year, lest it become a victim of distemper; and dogs are naturally meat eaters.

Well informed physicians now generally advise not to give meat to children before the fifth or sixth year. They have learned this much from the nature cure people.

Foods undoubtedly have a powerful influence, not only on the physical body, but also on the mentality and the emotions. These problems will be interesting subjects of investigation for the food chemist and psychologist of the future. In general, we may say that flesh foods are stimulating and feed the passional nature, while fruits and tender vegetables refine and stimulate brain and nerve matter as well as the intellectual, emotional and spiritual activities. Cereals, nuts and pulses build and repair the physical body and supply the body with heat and muscular energy.

The majority of animals adhere strictly to one kind of food, and therefore faithfully exhibit in their mental and emotional characteristics the effects of different food materials. Ferociousness we find personified in the carnivorous bulldog, lion, tiger and panther (that is why soldiers are fed on meat three times a day); gluttony and omnivorous voraciousness in the hog, chicken and hyena; cold-blooded cunning in the fox, and cruelty in the cat. The intelligence of the carnivorous animals displays itself mainly in the cruel cunning with which they stalk their living prey. It resembles in quality the low
intelligence of the human criminal.

Personifications of great physical strength, intelligence, endurance, patience, gentleness, fidelity, affection and self-control, we find among the vegetarian animals. The beaver, the arboreal ape and the elephant are especially noted for their intelligence; deer, antelope and sheep for gentleness; the horse for its almost human intelligence, affection and fidelity; oxen, elephants and camels for their great strength and endurance.

**Meat is detrimental to the child in every way,** physically, mentally and morally. The poisonous acids and alkaloids which it contains clog the capillary circulation, causing anemia, coldness of the extremities and defective elimination through the skin. This results in congestion in the interior organs, high blood pressure in brain and heart, headaches, nervousness, irritability, tendency to fevers, inflammations and catarrhal conditions.

With the meat, the child often absorbs the eggs of worms, tubercular bacilli, and other parasites and disease germs. Certain forms of epilepsy, St. Vitus' dance and hysterical conditions are due to uric acid poisoning and to other pathogenic materials and ptomains contained in flesh foods. Such patients, in times of crises, frequently emit pronounced odors of raw meat or uric acid. Strictly vegetarian diet, combined with other eliminative natural methods of treatment, cures the majority of these cases.

Most of these poisonous acids, alkaloids and ptomains contained in the flesh of dead animals are powerful stimulants. I have frequently noticed that people who have abstained from meat for a long time, when they first partake of it again experience sensations and exhibit symptoms resembling those of alcoholic intoxication.

We have learned that these stimulating extractives of flesh foods chemically closely resemble caffeine, thein and nicotine. The use of one or more of these stimulants invariably creates a craving for the others. This explains why a heavy meat eater is usually a confirmed coffee drinker or inveterate smoker, and vice versa; and why we find it almost impossible to wean people from one of these stimulants as long as they persist in taking the others.

The legumes or pulses—peas, beans and lentils—are close seconds to meat in acid-producing qualities. Eggs contain considerable ready-made uric acid and a great deal of sulfur and phosphorus. These may become dangerous to the organism. For these reasons, meats, legumes and eggs are always danger foods for the child.

Children brought up on such foods will show the effects in nervousness, irritability, lack of self-control, craving for cigarettes and alcoholic stimulants. The most serious aspect of this question lies in the stimulative influence of meat poisons...
on the sex centers. It is a well known fact, verified by close observation, that flesh foods stimulate the sexual passions to a marked degree. This tendency is greatly increased by the use of coffee, tea and alcoholic stimulants in the form of wines, liquors or medicines. If the sensitive nervous organism of a child is overwrought by these powerful irritants, there can be but one result; precocious sexual awakening.

From the third year the child may gradually adopt with slight appropriate modifications, a diet as outlined under Sec. I, No. 10, and Sec. X, No.7.

SECTION XL

Exercises in Infancy

1. Exercises in Infancy. Proper exercise is important from the very beginning of life. A baby will follow its natural instincts for exercise if allowed to do so, by working its arms and legs and writhing its little body in all directions, if not unduly hampered by tight clothing and bandages. A few nude air baths every day will afford excellent opportunity for baby's gymnastic stunts.

After he is a few months old he may be placed on his stomach, when he will exert himself vigorously by trying to raise his head, to turn around, or to raise himself with his arms. He will soon learn to roll over and to creep lie nay now be pulled up gently by his arms and lowered again a number of times in succession.

When three or four months old he may be lifted by one arm or by both arms; by the right arm and left leg, or by the left arm and right leg. When the baby is six or eight months old, he should be strong enough to rise from his back to a sitting position. This may be encouraged by holding down the feet. I have known a number of nature cure babies who at six months of age clung tightly to a stick while being lifted a few feet from the bed. Another good exercise greatly enjoyed by the youngsters is to roll them back and forth on a bed.

The average healthy child will secure ample exercise while learning to walk and run and while playing with simple toys or with other children; but this may be supplemented to good advantage by special exercises devised by the father and mother. Nothing is better for the health and happiness of both parents and children than to join in merry romp and play.

Between two and five years of age the child may be taught more difficult stunts, performed either by himself or with the assistance of the father or mother; but swinging the child high overhead, throwing him up and catching and other dangerous tricks should be avoided. They are risky and have very little effect in developing the body of the child. The best exercise at this age consists in outdoor play and games.
From the sixth year, the question of exercise becomes a more important one, especially since the children are confined for many hours in school rooms. If exercise at this time of life, through play and games and special gymnastics, is neglected, it may affect health, strength and efficiency of the child for life.

Those of good physique and ample strength may gradually take up and practice the exercises for adults outlined in sections XXI, XXII, XXIII, XXIV.

2. **High Chair**. A baby should not be put in a high chair until he is quite well able to hold the spine and head erect, and should never be left in a chair for any length of time. If a baby is forced to maintain a rigid, sitting position for a considerable time, before the bones and muscles are sufficiently developed, this may produce deformity of the spine. Maids and nurses, if not properly supervised, sometimes fasten a baby in a high chair and leave him there to take care of himself for long periods.

3. **Toys**. Since most babies have a habit of putting everything into their mouths, toys must be selected that can do no harm. They should have no paint, no sharp points or corners which might hurt the eyes or mouth, and must be of material which can be easily and thoroughly cleansed. Hairy and woolly playthings are unsafe, being unclean and germ carriers. Objects small enough to be swallowed must never be put within baby's reach. The simpler the playthings the better; a few clothespins, empty spools, or other simple objects are better than expensive toys.

**SECTION XLI**

**Baby's Ailments**

1. **Hernia**. As a result of a weakly or sickly condition of the mother during pregnancy and of faulty prenatal management, many children are born ruptured. So far I have not known a single nature cure baby that was born ruptured. Such defects are due to weakness of the tissues. This results from mineral starvation. The tissue walls contain too much mortar (protein) and not enough building stone (mineral salts). Prevention of hernia, therefore, lies mainly in proper diet of the pregnant mother, but all the rest of the prenatal regimen described in these pages is of great importance in preventing this and other ailments and deformities.

There are three principal points at which rupture or hernia may take place in infancy—at the navel, in the groin, and at the line between the navel and the lower end of the sternum. Other kinds of ruptures are extremely rare.
2. **Umbilical Hernia** This is a protrusion of the intestine at the navel. It is the most common rupture in infancy. Pulling on the cord during childbirth, urging at stool or violent crying may result in rupture. The umbilical ring first expands and this forms a pouch into which one of the folds of the small intestine protrudes.

   Treatment: Of primary importance is the diet as outlined herein. The baby must have plenty of fruit juices in order to reinforce the mineral salts in the milk. Cold bathing is very beneficial. The rupture itself should be cleansed several times a day with warm water. This must be followed by a wash with cold water mixed with lemon juice. Gentle, passive exercise, such as raising, lowering and twisting the limbs from side to side, also raising and lowering the body while supporting the shoulders and head, is of especial value.

   The rupture must be reduced and kept from protruding by placing over it a large button or other article of similar shape, wrapped in gauze and held in place by broad strips of adhesive plaster. The adhesive tape is fastened over the button crosswise and must be applied in such a manner as to draw the skin from all sides over the rupture. Instead of the button, a compress made of gauze may be laid over the rupture and held in place by one broad adhesive strip. The covering of the rupture must be removed and renewed every day in order to allow cleansing, as before described.

   When the child is old enough to exercise by himself, he should be taught special movements of the body and the limbs which develop the muscles of the abdominal region.

3. **Ventral Hernia.** This occurs along the middle line of the body between the navel and the breastbone, sometimes below the navel. The rupture may not be larger than the size of a pea or small marble, and may disappear on pressure. The treatment is the same as that of umbilical hernia.

4. **Inguinal and Scrotal Hernia** occur in infancy or in adult life; sometimes the inguinal canal does not close after the descent of the testes from the abdominal cavity into the scrotum, and the intestine descends through the open canal, thus producing the rupture. These forms of hernia become aggravated by coughing. They can be reduced immediately with gentle manipulation while the patient is lying on his back. This kind of rupture may be distinguished from hydrocele by the fact that in reducing it goes back easily with a gurgling sound. Hydrocele is not affected by coughing. A hernia is opaque to transmitted light; hydrocele, transparent.

   These ruptures should be protected with a well-fitting truss. This has to be removed daily for cleansing of the parts. Appropriate exercises, passive and active, together with cooling sitz baths and washes with cold water and lemon juice are the best remedies for these, as well as of other forms of rupture.
5. Congenital Hernia occurs in the form of inguinal hernia and has to be treated in the same way. Ruptures of any kind must be reduced and properly supported. Constipation and consequent urging at stool may cause or aggravate any form of hernia and must, therefore, be overcome by the right treatment described under section XXVI, No.1.

6. Colic. This is usually caused by indigestion due to overfeeding, improper feeding, or too frequent feeding. The intestines are distended with gas, giving rise to a severe pain. The baby cries sharply, alternately drawing its legs up to the body and kicking them away. One of the quickest means of relief is a small enema of warm water and gentle circular massage of the abdomen from right to left. Food should be withheld until the symptoms have disappeared. The giving of milk or other food may quiet the attack temporarily, but the pain is apt to return with greater intensity. Warm water may be given if the baby will swallow it.

A baby managed in the natural way prenatally and postnatally is not likely to suffer from this ailment. Constipated babies are more prone to it than others.

Colic may also be caused by sudden chilling. In that case a warm bath for five or ten minutes, followed by gentle body massage will bring about a warm reaction.

7. Convulsions. These cause a great deal of anxiety to the fond mother. They are always reflex symptoms of some slight or serious internal disturbance due to wrong management. They commonly result from some form of auto-intoxication caused by digestive disturbances, and the resulting systemic or drug poisoning. An inactive condition of the skin, bowels or kidneys will favor auto-intoxication and convulsions. If proper care is taken to keep the system pure, and the organs of elimination in active condition, convulsions will not occur.

The best treatment during an attack is a quick, cold rub all over the body; application of a whole body or trunk pack; gentle soothing magnetic massage, and neurotherapy treatment. These treatments draw the blood into the surface and relieve congestion in the brain and nervous system.

8. Ailments of Teething. Many ailments of children are laid to teething, but this is a mistake. Well managed, healthy babies go through the teething period without any trouble whatsoever. This is practically always true of nature cure babies. When, however, the little body is heavily encumbered with hereditary and acquired morbid materials, food poisons and disease taints, the process of teething will not run its natural course and may precipitate any form of disease crisis.

When teething is difficult, it is frequently associated with digestive disturbances. Diarrhea may alternate with constipation and vomiting is of common occurrence. The baby may be restless and fretful. He tries continually to bite on something in order to facilitate the projection of the teeth
through the hardened gums.

No teething lotions or soothing medicines of any kind should be given for the relief of pain in teething. They all contain poisonous sedatives which benumb and paralyze the nerves and have serious after effects upon the system. They usually contain opium in some form, or other narcotic drugs.

The only way to prevent these and other infantile ailments is to keep the little body as nearly normal as possible through the natural treatment described in these pages. If this is closely adhered to, it will prevent, in many cases, the development of even measles and other common eliminative infantile ailments.

During this critical period in the baby's life the diet must be extra light; starchy food should be reduced to a minimum and replaced by raw and cooked fruits and vegetables juices. Cooling sitz baths will help to keep the bowels active and to abate internal fever.

9. Acute Catarrhal Disease. Acute catarrhal diseases of infancy such as croup, cold in the head, acute bronchitis and whooping cough, are different forms of acute elimination through which Nature tries to purify the little body from hereditary and acquired accumulations of morbid matter, systemic poisons and disease taints.

In accordance with this conception of acute diseases, as purifying, healing efforts of Nature, we would not do anything to check or suppress elimination but cooperate with Nature in her purifying, healing efforts. How we do this has been fully explained in other parts of this volume. (Section VIII)

The natural treatment is very much the same in all acute inflammatory ailments. Feeding must be reduced to a minimum. If the baby does not insist upon eating, nothing should be given except water with acid or sub-acid fruit juices, such as lime, lemon, grape fruit and orange. If the temperature does not run high, say not above 100 or 102 deg, frequent ablutions with cold water at intervals of from one to two hours will be sufficient to promote heat radiation and elimination of morbid matter through the skin and other organs of elimination. If the temperature runs' higher, say between 102 and 105 deg, wet packs must be applied, and renewed when they become hot or dry.

The wet packs are of especial value in all kinds of cough; whether it be the ordinary cough, croupy cough or whooping cough. A whole body or trunk pack, with or without a throat pack, will give almost instant relief. In many instances where baby is making the night hideous for the anxious mother, with it's coughing, a well-applied whole body pack, or a combination trunk and throat pack, will relieve the coughing almost instantly, and induce restful sleep.
In serious cases it is always advisable to call in a natural
therapist or some other drugless physician, if one can be
reached.

The mother should not forget that all acute diseases, after
they have once developed, must run their natural course. She
must, therefore, not become impatient and lose faith in the
natural treatment if it takes a week or more to cure a common
cold in the head or an attack of bronchitis, or if it takes from
two to eight weeks to cure a case of whooping cough.
Serenity, patience and cheerfulness are the primary requisites
of the nature cure physician.

PART V

SECTION XLII

FIRST AID IN ACCIDENTS

A person in possession of a clean, healthy, supple body as a result of natural living and treatment, is not nearly as likely to suffer injury from accidents or to develop chronic after effects resulting from them as one whose body has lost its natural elasticity, keenness of sensory organs and recuperative powers through unnatural habits of living and the resulting Pathogenic conditions. This is well known to physical examiners for accident insurance concerns. When a body is in a pathogenic condition, a slight scratch may be sufficient to cause serious blood poisoning or a bruise or fracture may result in necrosis or tumor formation.

Natural methods of treatment are as efficient in giving first aid as in the treatment of acute and chronic diseases, though it may be necessary in serious cases to procure without delay the aid of a surgeon or trained osteopath, chiropractor or neurotherapist in order to examine for internal injury or to correct sprains, dislocations, fractures or other mechanical lesions. However, any layperson possessed of ordinary intelligence and common sense can apply the first aid methods herein described.

In many instances, natural treatment applied in time will greatly ameliorate the suffering and establish the best possible conditions for perfect recovery. The old time drug treatment which was held to be indispensable in cases of accident is as useless and harmful under these conditions as in the treatment of acute and chronic diseases. Much experience in all kinds of emergencies has convinced me that this is true.

In case of an accident it is of primary importance not to become excited and thereby to lose presence of mind and self-control. It is only by remaining cool and relaxed that one can think clearly and decide quickly upon the best course to pursue.

In first aid as well as in acute diseases the quickest and best results are obtained by hydropathic and manipulative treatment. It is, therefore, necessary for the student of emergency work to thoroughly study the methods and applications described under those headings. In order to facilitate quick and ready reference I shall treat the various occasions for first aid in alphabetical order.

1. Alcoholism. Acute alcoholism may result in complete collapse and stupor. It has frequently happened that a person
found in an insensible condition in a public place is mistaken for a drunkard in a stupefied condition, and carted off to a police station, when in reality he is suffering from injury, -a stroke of apoplexy, sunstroke, heat prostration or from some other serious physical disorder. In order to prevent such mistakes, which might easily result in the death of the sufferer through lack of proper care, it is necessary to smell the breath, which, in cases of alcoholism, will immediately tell the story.

a) The best treatment for alcoholic stupor consists in brisk cold rubs, followed by good massage and neurotherapy treatment, calculated to stimulate and to revive the activity of the brain and nervous system. An enema of a Warm, normal salt solution is also very beneficial. When the patient revives, half a cup of black coffee with lemon juice will act as a mild heart stimulant.

b) Delirium Tremens is a form of acute mania brought about through temporary paralysis of the brain centers which are the seat of reason, Will power and self control. The lower animal emotions are running amuck and in many such cases various forms and symptoms of abnormal psychism prevail. The horrible experiences and visions of people in this condition are not always delusions and hallucinations but frequently are the result of clairvoyance and clairaudience on the lowest spiritual or astral planes, the purgatories and hells of the theologians.

The various phases of abnormal psychism are fully treated in Volume IV, Eugenics. This abnormal functioning of the sensory organs of the spiritual body is brought about through the temporary paralysis of the sensory organs of the physical body;

In order to prevent complete collapse it may be necessary to give at increasing intervals and in decreasing doses, alcoholic liquor, coffee, tea or other light stimulants to revive and strengthen the animal magnetism of the physical body. Tincture of passiflora administered every two or three hours in from ten to twenty drop doses is a good non-poisonous vegetable tonic. Meat broth, Tartar sandwich and other flesh foods may be given until the patient has recovered from the abnormal psychic condition.

The hydropathic treatment consists of cold rubs and cold douches, wet packs and cooling sitz baths. Massage and neurotherapy treatment is of great importance in such cases, not only for its mechanical but also for its electromagnetic effects.

Epsom salt or sea salt rubs also have a positive magnetic effect upon the system. Hot bathing, bromides and other "sedative" measures only aggravate the condition because they have a weakening, benumbing effect. Those who apply such sedative remedies forget that delirium tremens and other maniacal conditions are the result of weakness, exhaustion, and of a benumbed and semi-paralyzed condition of the brain.
and nervous system, and that, therefore, tonic, energizing treatment is required instead of benumbing, sedative remedies and applications.

When the patient has recovered from the effects of acute alcoholism he should undergo thorough systematic natural treatment in order to eradicate completely the craving for alcoholic stimulants. We have treated and permanently cured many victims of the drink habit who had undergone all sorts or drink cures without permanent results. As drug cures for the drink habit work on the principle of "poison kills poison". It is Beelzebub against the devil. While drugs may temporarily kill the craving for alcoholic liquors, the results thus obtained are not permanent. As the effects of the drug treatment pass off, the old craving returns and the drugs themselves have a weakening and deteriorating effect upon the system. Such Cures do not influence the moral nature.

Natural treatment with its "back to Nature" life, its pure food diet, and its educational influences through daily lectures and suggestive treatment, arouses higher ideals, strengthens will power and self control, and thus overcomes in a natural way the desire for alcoholic stimulants as well as habit creating drugs. It accomplishes this, not by the introduction of other poisons but by the purification of the organism and by the presentation of higher and purer ideals. One who, after such physical, mental and moral regeneration, has tasted the sweetness of the natural life will never again crave the gross deceptive gratification afforded by indulgence in alcoholic liquors and habit-forming drugs.

Strict adherence to a natural regimen for three or four months will take away all desire for alcoholic or drug stimulation. Patients have confessed to me that they did not backslide on account of an irresistible craving, but through careless surrender to temptation. Self control must be strengthened by educating the moral nature. Antidotes. See Poisoning, no 26.

2. Apoplexy. Apoplectic stroke and the resulting paralysis are caused by the breaking of one or more blood vessels in the brain. If the hemorrhage occurs in the right brain hemisphere, the left side of the body will be affected by paralysis on account of the crossing of the nerve tracts in the medulla and spinal cord. If the hemorrhage occurs in the left brain half, the right side will be affected. The extent of the paralysis depends upon the amount, of damage done to the brain centers in the area affected by the hemorrhage. The breathing is labored and stertorous, the face is flushed and purple in color, the features are twisted and drawn to one side, the pupils of the eyes are usually dilated.

a) The head and shoulders should be slightly raised. Quick, cold salt rubs followed by stimulating manipulative treatment will draw the blood away from the brain into the surface and extremities. A lay-person can give the extremities and fleshy parts of the body a good, thorough kneading, rubbing and
stroking, but a trained masseur or neurotherapist should be procured as quickly as possible to complete the treatment.

b) Wet packs applied to the body and, the extremities will draw the blood away from the congested brain area. A warm normal salt enema (Sec. XVIII, No.4) will help to establish normal circulation. A hot mustard bath applied to the feet or, better still magnetic treatment (p.397) will divert the blood into the lower extremities.

c) After consciousness has been restored, the patient must undergo thorough, systematic natural treatment in order to eliminate from the system the, pathogenic materials which have caused high blood pressure and the hardening and occlusion of the blood vessels in the brain and all through the body, and which brought about the hemorrhage and resulting paralysis. **No alcoholic or drug stimulants should be given because they increase blood pressure to the brain.**

d) In cases of **concussion of the brain, apoplectic stroke, or of hemorrhages from the lungs or stomach**, the patient must not be transported in a vehicle because the jolting might aggravate the condition. The sufferer must be carefully carried on a stretcher.

Of the many patients we have treated after a first apoplectic stroke, not one, as far as I can remember, has suffered from a second attack, provided of course there has been careful adherence to natural ways of living.

3. **Artificial Respiration** In many kinds of accidents, such as drowning, strangulation, asphyxiation by poisonous gases, and in serious cases of fainting and stupor, it may be necessary to resort to artificial respiration in order to restore normal breathing. There are several good methods for this purpose.

a) Quickly remove the clothing from the upper part of the body; lay the patient prone upon his stomach, place a small wad made of clothing or any other material at hand, under his forehead in order to elevate nose and mouth sufficiently to allow free breathing.

![Fig. 24](image)

The operator kneels athwart the legs of the sufferer and places his spread hands on both sides of the small of the back and then exerts gentle but steady pressure, thus compressing
the lower ribs and chest; he then gradually releases the pressure, allowing the lungs to fill with air. This alternating compression and relaxation of the chest must proceed at the same rate as the normal tempo of breathing, which is about fifteen breaths to the minute in adult life and a little more than this in childhood. With adults, therefore each complete movement in artificial respiration should consume about four seconds including expiration and inspiration, while in children it should consume about three seconds.

b) The same method may be applied while the patient is lying on his back. Make a roll of clothing and shove it under the small of the back so that the head lies lower than the chest. Then kneel astride of the hips, place both hands, fingers spread as far as possible, on the lower ribs below the nipples of the breast and count slowly one, two, three, four; while counting one and two, compress the lower chest gently but firmly and relax the pressure while counting three and four. Continue this alternating compression and relaxation until normal breathing commences (provided life is not extinct). A sudden trembling and heaving of the chest and flushing of the face will indicate when natural breathing commences. While compressing the chest, the operator should at the same time apply strong vibration. This is accomplished by vibrating the hands loosely and vigorously from the wrist joint. The slow, regular counting corresponds to the tempo of regular normal breathing.

c) (Fig. 25a, b, p.385) Another, more commonly applied method of artificial respiration, is the following: The patient lies upon his back; a small roll of clothing or other soft material is placed under the small of the back in order to raise the chest and to facilitate expiration. Inspiration is induced by raising the chest through bringing the arms above and back of the head; expiration is produced by returning the arms downward and in an outward, circular movement to the sides of the body, doubling them at the elbows and pressing the forearms on to the chest (Fig. 25 b). Compression must be followed by relaxation. This alternating compressing and releasing or raising of the chest should also be continued at the rate of fifteen complete movements to the minute for adults and twenty for children, or it may be regulated by counting as in the operation previously described.
The first method (a) is to be favored because it prevents the falling back of the tongue into the throat and because it facilitates the escape of water, mucus or froth from the mouth. This is especially important in cases of drowning when the lungs are more or less filled with water.

**d)** (Fig. 26) The best method for facilitating the escape of water from stomach and lungs is the following: Lay the victim prone upon his face, stand athwart his body, place your hands under his stomach and raise him at short intervals, thus partially doubling the body upon itself. This compresses the internal organs and facilitates the discharge of fluids through the mouth.

**4. Asphyxiation or suffocation** is a condition of unconsciousness and insensibility resulting from suspended respiration. It is caused by a deficiency of oxygen in the system and an excess of carbon dioxide. This may be
produced by strangulation, as in hanging, by smothering or internal obstruction, as in choking, drowning, or by the inhalation of smoke or poisonous gases.

The treatment consists, first in artificial respiration described previously; and, secondly, in restoring the circulation of the blood and nerve currents. This is best accomplished through hydropathic and manipulative treatment described under acute alcoholism. The revival of an asphyxiated person may require long continued effort. Cases are known where by three or four hours of persistent effort, people have been revived after hanging or other forms of strangulation or suffocation.

a) The victims of carbon dioxide asphyxiation die because this gas is heavier than oxygen and therefore does not allow this life-sustaining element to enter into the lungs and tissues of the body. A pulmotor may help to force the oxygen into the lungs and to expel the CO2.

b) While rescuing a person from a room filled with smoke or poisonous gases, a wet handkerchief or other piece of wet cloth should be tied over the mouth and nostrils. Breathing should be restrained as much as possible. Care must be taken not to strike a match as it may explode the hydrogen gas. The windows should be opened or broken at once. This will enable the life-saver to take an occasional breath of fresh air while trying to find and to remove the victim of asphyxiation to the outer air.

5. Bandages. When bandaging wounds, fractures or other bodily injuries, care must be taken not to apply the bandage too tightly. This might seriously interfere with the circulation, especially if swelling develops in the injured parts.

a) Triangular Bandage. One of the most useful bandages in accidents is the triangular bandage. This may be prepared from any square piece of cloth by folding it diagonally in the shape of a triangle. Figures 27, 28 illustrate the application of the triangular bandage to a broken forearm Figure 29 illustrates other uses of this bandage. Fold a square piece of
muslin or other material into triangular form and place against
the body underneath the injured arm. Point A is drawn
over the uninjured shoulder; point B is brought up over the injured
arm and shoulder and knotted or tied to point A behind the
neck.

The projecting flap D is folded over the elbow and fastened
with a safety pin. This supports the arm in a comfortable
position.

The inner surface of the hand must be turned inward and
the thumb upward. Fig. 29 shows the application of the
triangular bandage to injured hands and feet.

b) Figure Eight Bandage. Fig. 30 illustrates the Figure
Eight bandage applied to hand and foot. A long bandage, three
or four inches wide is applied with its center to the injured
part. The ends are then drawn crosswise around the wrist or
ankle and knotted or pinned with safety pins.

c) Roller Bandage Figures 31, 32 illustrate the application
of the roller bandage. This bandage may be from a few feet to
a few yards in length and of any width best suited for its
purpose. The bandage is first rolled up either in a single roll or
in two rolls from each end (Figs. 31, 32). The single roll
bandage is rolled up from one end and applied by unrolling
from one end. It should be applied by winding smoothly and
evenly around the injured part, but this is possible only when
the part is of even thickness. If the injured part is of uneven
thickness, as in the case of an arm from the wrist upward or a
leg from the ankle upward, the bandage in order to be applied
smoothly and firmly must be reversed upon itself. This is
done by placing the thumb upon the bandage where it is to be
folded back upon itself, as illustrated in Fig. 31.
d) **Double Roll Bandage.** The double roll bandage is applied with its center over the injured part; both ends cross in the back and are then wrapped around the part in opposite directions. (Fig. 32, no 5c))

e) **The T Bandage** has been described under Sec. XV, No.18.

f) **Head Bandage.** Bandages suitable for injuries to the head or for holding in place compresses to the head are applied as shown in Fig. 33. One bandage is drawn over the head to point c and fastened under the chin at a. The other bandage, no 2, is drawn over the back of the head and the base of the skull, and fastened over the forehead.

g) **When the chin or lower jaw is injured,** bandage (a), which supports the chin, is knotted on the top of the head. Bandage (b) is applied over the chin and knotted at the back of the neck. (Sec Fig. 34.)

6. **Bites** by snakes, dogs, cats or by persons in an enraged or maniacal condition, should be sucked out immediately if they can be reached, by either the victim himself or by a friend. The mouth of the one who performs this operation must not contain wounds or abrasions and should be thoroughly cleansed with water after each withdrawal of blood. The wound, if necessary, should be widened by an incision and
cleansed with dilute lemon juice. Immediately after this there should be applied a wet bandage or wet pack.

The elimination of any possible infection must be promoted through fasting or raw food diet, manipulative treatment and all other natural methods described in this volume. Of special importance in this respect is the bed sweat bath followed by cold ablutions.

In cases of snake bites, never administer whiskey or other alcoholic liquors, nor stimulating drugs. This is not only absolutely useless but decidedly harmful and dangerous. According to reliable statistics, less than eight per cent of people bitten by rattlesnakes or other poisonous reptiles die from the effects of the venom even though no whiskey is administered. On the other hand, many cases undoubtedly end fatally on account of the whiskey treatment. Excessive stimulation is always followed by corresponding depression and frequently by complete collapse. This is most likely to occur when large quantities of the fiery liquor are poured into people who are not accustomed to its effects.

7. Bruises, Bumps and Contusions. These are treated best by the application of wet packs or clay packs. See Sections XV and XVI.

While bruises and bumps do not bleed externally, the torn blood vessels may bleed internally and cause red or black discolorations. Such internal hemorrhage can be best arrested by firm pressure applied around the affected area; that is, by pressing some hollow object such as a spoon or a cup firmly around the bruise. The cooling packs or compresses will allay any tendency to inflammation or suppuration. Raw beefsteak applied to bruises acts in a manner similar to wet packs.

8. Burns and Scalds. When the clothing is afire one should not run about excitedly, as this will only fan the flames to greater intensity. The best way to extinguish the fire is to throw oneself prone upon the ground and smother the flames by rolling. Rugs, blankets, pieces of clothing or any other material within reach may be used by the victim of the accident or by those who are trying to aid him, to smother and to extinguish the flames. Rolling on the floor prevents also the inhalation of the flames or smoke and the burning of face and hair.

While removing the clothing from a body injured by burns or severe scalds, do not try to tear it off by force, but cut around the places where the clothing adheres to the flesh.

The best treatment for burns and scalds consists in applying a mixture made of ordinary baking soda (bicarbonate of soda) and ordinary boiled oil (linseed oil) or olive oil. This simple remedy which can be procured in almost any household, is of wonderful efficacy in the healing of burns and scalds. It allays pain even in severe and extensive sores and prevents the formation of blisters while greatly facilitating the healing
process. The alkaline sodium neutralizes the poisonous acids which form in the sores and the oil keeps the flesh in a softened condition and prevents caking and cracking.

In cases of very extensive burns or scalds, immersion under water of body temperature or slightly below, has been found very beneficial. In such cases the patient may remain suspended under water in a hammock for days or weeks at a time until the sores are healed sufficiently to allow exposure to the air.

Burning of the eyes and face by strong acids, fresh slaked lime, etc., is best treated by the immediate application of the olive oil and baking soda mixture.

For the treatment of shock due to scalds or burns, see 'Shock'.

**Carrying** an unconscious person (see Transporting an Injured Person, p.417).

9. **Choking.** Infants and children frequently choke as the result of swallowing small playthings or other foreign objects. Adults may choke from getting fish bones stuck in their throats or trying to swallow large pieces of meat.

If the patient is a child, place him face downward over your lap, and slap him vigorously between the shoulders. If this does not remove the obstruction, then compress the nostrils, which forces him to open the mouth and throat widely, introduce the fingers of the other hand quickly into the throat and try to grasp the obstructing object. If this is not possible, tickle the palate with a feather, a finger, or with a handkerchief rolled to a point. The tickling will cause coughing or hawking which may dislodge the obstruction.

An adult may throw himself over a chair or table, the head hanging downward, while another slaps him vigorously between the shoulders or, if necessary, performs the operations described in the previous paragraph.

10. **Convulsions.** These are due either to congestion of the blood in the brain, to abnormal pressure of gas on the heart, or to excessive irritation of the brain or nervous system by toxic substances.

The treatment must be adapted to the individual condition. Most of these have been described in Vol. V under Epilepsy, Uremia poisoning and other forms of diseases.

a) For first aid the patient should be placed in a recumbent position with the head slightly raised. Alternating hot and cold fomentations are most effective for drawing the blood or irritating toxins from the affected area into the surface. The patient should sip hot water mixed with a little lemon juice. An enema of normal salt solution and of blood temperature should be administered as soon as possible. Wet packs applied
to the neck, trunk or extremities will also draw the blood into the surface and thus relieve inner congestion and promote elimination of toxic substances. A full hot bath of body temperature of from ten to fifteen minutes duration may give quick results in serious attacks. This should be followed by a brisk cold saltwater rub.

In convulsions of infants the body first becomes cold and rigid, then the skin breaks into a clammy perspiration, the pulse is weak and rapid. This is followed by convulsive movements and later by a semi-comatose condition which usually passes into a natural sleep.

After the first aid measures herein described have given temporary relief the underlying causes must be overcome by natural methods of treatment

b) Uremia convulsions frequently occur in the course of Bright's disease and of diseases which cause prolonged retention of the urine in the bladder. In such cases it is imperative to increase the activity of the skin in order to compensate for lessened elimination through kidneys and bladder. The best way to accomplish this is to apply the bed sweat bath described under Sec. XIV, No. 5, p.143.

Sufficient hot water bags, bottles, or heated bricks must be placed outside of the whole body pack and under the outer blanket covering so as to produce free perspiration. The patient remains in the pack from fifteen to thirty minutes, as long as he can endure it.

After the removal of the pack he is quickly rubbed down with cold water, either in a bathtub, spray room or in bed. He is then covered well with blankets in order to induce free "after perspiration". This procedure is repeated as often as the patient can endure it and react to it properly. After the pack has been applied, the patient should drink freely of hot lemonade made with brown sugar or honey. This will promote free perspiration.

Expert massage and neurotherapy treatment should be given to stimulate the circulation, to promote the elimination of morbid matter and to correct spinal or other mechanical lesions. Juniper berry tea (Sec. XIX, No. 5) will stimulate the activity of the kidneys. Fasting is imperative. It must be extended for days or weeks, according to the nature of the disease back of the convulsions. In cases of serious ailments such as Bright's disease, inflammation of the bladder, subacute and chronic prostatitis, the fasting must be followed by raw food diet for weeks or months at a time.

Hot, normal salt enemas should be given to cleanse the lower intestines and to stimulate the vital activities.

For treatment of Epileptic convulsions see No. 14, p.398, this Section.
11. **Cuts and Wounds.** Small cuts or wounds should be thoroughly cleansed with warm or cold water and then treated with dilute lemon juice. Air and light are the best of all healers. It is injurious to close cuts with adhesive plaster, because it prevents elimination and shuts off air and light. However, in case of large wounds, the edges may be held together with narrow strips of adhesive tape just sufficient to keep the lips together for healing and to allow drainage. When the bleeding has stopped, the wound should be left uncovered if this can be done without exposing it to the pollution of impurities; or, the covering should consist of just enough porous gauze to protect it.

If the wound should prove painful or become inflamed, frequent bathing in cold water or allowing a stream of cold water to run over it, is the best remedy. If the wound is large enough to cause serious or dangerous hemorrhage, appropriate treatment must be applied. For this see "Hemorrhages", No. 18 (a), page 402.

**Delirium Tremens.** (See Alcoholism, p.379.)

12. **Disease, Sudden Onset of.** The simplicity of the natural treatment enables us to apply the most efficient treatment at the sudden onset of any disease whatever. While the medical man has to wait for days and sometimes for weeks before he can find out what the exact nature of the trouble is and apply his specific remedy, the natural therapist gives the most effective treatment from the first manifestation of symptoms. In that way he may be able to abort or to avert many serious diseases which might end fatally if neglected for a few days.

At the first appearance of great weakness, of aches and pains in any part of the body, of increased temperature and quickening pulse rate, a normal salt enema (Sec. XVIII, No. 4, p.165,) of body temperature should be administered in order to thoroughly cleanse the lower intestine. This should be followed by a full sheet pack (Sec. XV. No. 7) or by a trunk pack or, if reaction is unsatisfactory, by a full sheet bed sweat bath (Sec. XIV, No. 5, p.143). (See also description in Uremic Poisoning, No. 10. (b) 4 p. 394.)

Fasting must be enforced from the appearance of the first symptoms of malaise or acute inflammatory activity.

If there are signs of poisoning or of severe inflammation of, the stomach and intestines, vomiting should be induced immediately by means of drinking copious quantities of lukewarm water, either pure or mixed with salt or mustard. If vomiting cannot be induced in this way, tickle the throat with a feather or piece of cloth drawn over a sliver of wood. After thus thoroughly cleansing the stomach, allow the patient to drink freely of water mixed with the juice of acid fruits.

Neurotherapy treatment should be given at once to promote heat radiation, elimination of morbid matter, and to correct mechanical lesions.
A few days of such natural treatment will suffice in most cases to restore the system to normal condition. If an acute disease should develop, it will run a much milder end safer course after prompt natural treatment, and the results obtained will be infinitely better than under the old time drug treatment.

Carefully observe the following warnings, though you may find contradictory advice in books on naturopathic and physical and natural culture treatment: **In acute conditions never apply hot water applications nor the ice pack; neither give cold water enemas.** They are very dangerous, as they may suppress the inflammatory process and bring about fatal collapse. In cases of serious shock or collapse where the vitality is too low to react to cold applications, alternating hot and cold fomentations are in order, and the wet packs may be wrung out of hot water instead of cold water.

If the hands and feet remain cold and bloodless the best remedy for bringing the blood to the extremities is good magnetic massage. After the manipulative treatment, firmly hold the hands of the patient or grasp the feet around the ankles and **will** the blood to flow into the extremities. The magnetic treatment must be continued until the hands or feet warm up.

The hot bath or hot water bag treatment produces warmth temporarily but is followed, in accordance with the law of action and reaction by cold reaction; therefore the anemic condition of the extremities is only made worse by such hot applications.

**Drowning** (See No. 3, pg 383)

**13. Ears, Foreign bodies in,** locate the foreign body by using an ear speculum and head mirror. Turn the patient on the affected side and use a syringe from below, to straighten the canal, pull the outer ear up and back. In some cases forceps made of fine wire may be necessary. Living insects in the outer canal may be killed by the injection of alcohol or oil and then removed by syringing or by the wire loop. In cases of peas or beans, do not use water; it will make them swell. Use a wire loop or attach a strip of adhesive plaster to the foreign body and pull it out that way.

Foreign bodies in the nose may be removed in a similar manner.

**14. Epileptic Convulsions.** Nothing must be done to check or suppress the convulsion; this would be very injurious. All that can be done during an attack is to place the patient in a comfortable position and to elevate the head slightly. A neurotherapist should give firm inhibitory treatment over the upper cervical vertebrae and at the base of the skull. Immediately apply rectal dilatation.

If the fit occurs in the house, the patient should be exposed to a draft of fresh air. Push the lower jaw forward so that the
lower row of teeth projects over the upper. This will keep the windpipe open and prevent choking and suffocation. Push a piece of wood padded with a cloth, a cork or a rolled handkerchief between the teeth in order to prevent biting of the tongue. The opening of the clinched hands is useless.

After the attack the patient should rest until its effects have worn off. The treatment for the cure of the disease must be administered between the attacks. Two-thirds of such cases that have come under our treatment made permanent recoveries.

**Exhaustion.** (See Heat Exhaustion, p.401.)

**15. Eye Injuries.** (a) Black eye. Caused by external injury, blows, etc. Natural treatment: Cold applications applied immediately will prevent discoloration and will alleviate inflammation.

Burns. See treatment for burns, No. 8, p.391.

b) Foreign bodies in the eyes, such as cinders, bits of sand, etc. These are usually found imbedded in the cornea or in the lid. Pull the lid outward and bend it backward over a toothpick, a match or other bit of wood, thus exposing the inner surface. Then remove the obstacle with a bit of cotton if it is imbedded in the lid; or if necessary with a toothpick or sharp instrument if it is located in the cornea. Treat inflammation with cold compresses and cold eye baths.

c) Perforating Wounds. Perforating wounds of the eyes should be treated with cold compresses and cold eye bath. The patient must remain absolutely quiet and not expose the eyes to any strain whatever. If the sight is lost and symptoms of sympathetic inflammation appear in either eye, removal of the affected eye may become necessary, but this will seldom be the case if the cold compresses and the potato compress and cold ablutions are applied faithfully from the start (Sec. XV, Nos. 1, 4, pp. 147, 148). In any case of injury do not use vaseline, atropine or antiseptics.

**16. Fainting—Insensibility.** Find out first whether the unconscious one is alive and breathing. Hold a mirror, piece of glass, bright piece of metal or a feather before the mouth and nose. If the patient is still breathing, the bright surface will be dimmed by the breath, or the feather will move.

a) The following is another test for determining whether life is extinct. Raise the eyelid and touch the white of the eye. If life is not extinct, the eyelid will twitch. Observe the odor of the breath. It will indicate such poisons as alcohol, chloroform, ether, etc. If the tongue has been bitten it indicates epilepsy. If the eyes are sensitive to touch and light, there is no brain injury. Unequal contraction of the pupils indicates brain trouble. Pupils contracted to pin points indicate opium poisoning. Slow, weak breathing indicates collapse or shock. Snoring or stertorous breathing and slow, weak pulse
indicates brain trouble. Rapid pulse points to sunstroke. A hot skin and rapid pulse indicate sunstroke or high fever. Cold skin and weak pulse may be the result of fainting, freezing, or of acute alcoholism. High fever should be treated as described under treatment of acute diseases (Sec. VII {pg. 76, 77).

b) If the patient is still breathing, place him in a comfortable position, the head somewhat lower than the rest of the body. Open or cut the clothing wherever it constricts the body, and expose the patient to a draft of fresh air, if in the open, fan the air, over his face.

c) In order to stimulate heart action, apply, alternate hot and cold compresses to the chest; sprinkle or dash cold water over the face and neck; also apply alternate hot and cold fomentations to the, spine. Massage and apply passive movements to the extremities. If the, breathing is very slow and faint, apply artificial respiration (No 3. page 383). Dash cold water on the neck and on the soles of the feet. Give cold salt water rubs, all over the body. Administer a, warm normal salt enema (Sec. XVIII, No. 4, p.165.). Do not try to administer water or stimulants while the patient is unconscious; it would only choke him.

d) When he revives do not give alcoholic liquors or other poisonous stimulants. The reaction might prove fatal. Give sips of fresh water mixed with acid fruit juices, or, black coffee or tea in small quantities; repeat until full consciousness has been restored.

e) Try to find out what caused the unconscious condition. It may be the result of any one of the following causes: Fainting; collapse, shock, asphyxiation by gas; drowning or other means, acute alcoholism, opium, chloroform, ether or other drugs, sunstroke, apoplexy, epilepsy, convulsions, injury to the brain by concussion or fractured skull, or it may be caused by certain diseases of the heart stomach or kidneys. Treat accordingly.

17. Fractures. In case of fracture, a physician or Surgeon, must be secured without delay. In the meantime excessive bleeding may be stopped as described under "Hemorrhages" (p.402). Swelling may be reduced by wet packs and cold ablutions.

18. Freezing. Frozen limbs, ears, nose or other fleshy parts, of the, body should be, rubbed vigorously with ice water, or snow. Great care, however, must be taken not to break the frozen parts; they are brittle and may break easily.

If a person has become unconscious through freezing, he must be taken into a cold room and treated with cold rubs by means of ice water or snow, until the circulation in the various parts is restored. As before stated, great Care must be taken not to break the frozen parts.

If breathing and heart action are very low or imperceptible,
artificial breathing, with due precautions, must be at once resorted to. The individual condition must determine the best method to be employed. When normal breathing commences, place the patient in a cold bed and heat the room very gradually.

When the body becomes warm, rub with warm flannels, but the frozen parts must still be treated with cold applications and snow rubs.

Warm the body from within by giving hot lemonade with brown, unrefined sugar or honey. Black coffee with lemon juice will stimulate heart action and circulation.

To drink alcoholic liquor in order to keep warm is extremely dangerous. The benumbing after effects of this and other strong stimulants will induce numbness and sleep when wakefulness is necessary to resist the freezing.

19. Heat Exhaustion is usually the result of injudicious diet in summer, excessive clothing, and of working in close, hot, illly ventilated rooms. The principal symptoms are faintness or syncope; a cold and damp skin and a rapid and feeble pulse. When death results it is due to heart failure; but most cases recover. It is not as often fatal as sunstroke.

a) The patient should be removed to a cool place. Hot lemonade will stimulate the heart action; a brisk, cold rub and wet packs, if necessary reinforced by hot water bottles will restore the activity of the skin. (See Bedsweat Bath, Sec. XIV, No. 5, p.143)

b) Both in sunstroke and heat prostration the head should be frequently laved with cold water. If the body temperature is subnormal and death seems imminent, the legs should be wrapped in woolen blankets saturated with hot water. Care must be taken not to scald the flesh. Around the wet blanket wrap several layers of dry sheeting or a dry blanket in order to retain the heat. The patient should take at intervals small quantities of hot lemonade.

Heat Prostration (See Heat exhaustion, p.401.)

20. Hemorrhages. (a) Hemorrhages from the mouth. When the blood is of dark color and looks as if it were mixed with coffee grounds or food materials it comes from the stomach and the hemorrhage is caused by cancer. If the blood is mixed with food materials but looks bright red, the hemorrhage is caused by ulcers of the stomach. If the hemorrhage is from the stomach, the patient should be placed in a recumbent position. A trunk pack will draw the blood away from the stomach and relieve congestion. The patient should sip at frequent intervals small quantities of cold water mixed with lemon juice, and should be allowed to rest.

b) Hemorrhage from the Lungs. When the blood is bright red and foamy and free from food materials, it comes from the
lungs and is caused by breakdown of the lung tissues. It is not necessarily directly fatal. Under natural treatment of lung diseases, hemorrhage frequently occurs during the crisis periods and is then a form of elimination. In many cases, recovery from tuberculosis has been preceded by copious hemorrhages. The patient should be kept in bed in order to give the disrupted tissue a chance to heal. The treatment must be directed to the underlying disease.

c) Hemorrhages from Cuts and Wounds. If the blood is bright red and comes in spurts, it is an indication that some important artery has been severed and a ligature should be applied without delay above the wound. If on the trunk of the body, pressure should be made above the wound, between it and the heart. Any solid object, a piece of wood, rock or anything convenient, held in position firmly by a bandage or belt will serve the purpose. (Figs. 35, 36.)

d) If the blood is dark in color and flows smoothly, then some vein has been opened and the ligature should be applied just below the wound. (Fig. 37) Any strap, rope or handkerchief may be used for this purpose, but a rubber hose, if it can be procured, is best suited on account of its elasticity. The ligature may be applied more tightly by inserting a stick, pipe or similar object below the knot and twisting it. (Fig. 35.)

Do not try to remove any clots of blood; they are Nature's provision for stopping the hemorrhage. Hemorrhages from large arteries may be stopped temporarily by compressing the blood vessel with the fingers. In order to do this, one must know where to find the arteries.

e) For an injury on the side of the upper part of the head, the temporal artery, must be Compressed with the thumb. This artery is located about three-quarters of an inch in front of the opening of the ear underneath the temporal bone. (Fig. 38)
If the injury is in the back of the head, the occipital artery must be compressed with the thumb. It is located about an inch from the center of the back of the ear. (Fig. 39) The facial arteries can be compressed by exerting strong pressure at a point one inch in front of the angle of the lower jaw. (Fig. 40.) The arteries pass over the jaw at these points. They should be pressed at the same time on both sides.

The common carotid artery can be reached at a point one and a half inches above the joint between the breastbone and the collar bone. Pressure may be exerted inward and backward. (Fig. 41.)

The subclavian artery can be reached at a point behind the middle of the clavicle or collar bone where the hump of this bone is felt. First lower and draw the shoulder forward, then press downward and backward with the thumbs or with the fingertips of both hands. The pressure must be firm and persistent. (Fig 42.)
The axillary artery can be compressed by first raising the arm, pressing it outward and backward, and then compressing the artery on the inner surface of the upper arm. (Fig. 43.)

The brachial artery passes along the inner border of the biceps muscle. First extend or raise the arm, then press outward and backward. (Fig. 44.)

The radial and ulnar arteries in the wrist may be compressed readily with the fingertips. (Fig. 45.)

The great femoral artery in the upper leg can be reached best in the groin just in front of and a little inside of the femur bone. Compress with the thumbs or by using as many fingers as are needed.

The popliteal artery can be reached by strong pressure in the central part of the ham, applied, while the patient is lying on his stomach, directly downward.

The wounded part should be raised as high as possible.

Cold water is very effective for stopping hemorrhages. If possible it should be allowed to run over the wound in a constant stream. This inhibits the circulation and favors the clotting of the blood. Care must be taken not to run the water directly on the wound as this might prevent the forming of clots. In order to accomplish this it may be well to place a cup or saucer or some other protecting object directly over the wound.
Only boiled or aseptic bandages should be applied to the wound. **Clay or mud must never be applied to open cuts or wounds.** Water mixed with lemon juice applied directly to the wound acts as a natural antiseptic and astringent, thus favoring the clotting.

**21. Hicough or Hiccup.** This is a spasm of the diaphragm, caused by nervous irritation of some kind. It may be due to digestive disturbances or to irritation caused by systemic or drug poisons. In chronic form we find it frequently associated with mercurial, phosphorus, strychnine and other drug poisoning.

Ordinary hicough requires little or no special attention. If it persists, one of the best remedies is to continuously sip and swallow water until one or two of the spasms have been missed; anything that will break the regularity of the spasm will stop it. Out of this fact grew the old custom of "frightening the hicough" by a sudden motion or exclamation.

In its most serious forms, in cases of drug poisoning, we have always succeeded in alleviating and in most instances overcoming the spasms by the natural treatment. Certain neuropathic moves give excellent results.

**Insensibility.** See "Fainting" No. 16, p.399.

**22. Lightning Stroke.** If a stroke of lightning results in shock or collapse, treat as described under "Shock", p.414. If it results in burns, treat as described under "Burns and Scalds" (p.391).

**23. Mania.** A sudden maniacal outbreak, whether the result of an attack of insanity, of acute alcoholism or of great emotional excitation, is best treated by cold applications such as cold sprays, cold sitz bath, hip bath, quick submersion under cold water, or by cold wet packs.

Soothing manipulative and magnetic treatment is very effective.

It is wrong to submerge such patients for hours or days in warm or hot water. Such sedative treatment is as weakening as opiates and hypnotics and will only aggravate the underlying conditions which are always negative in character.

Such patients should have nothing but vitalizing, upbuilding treatment. Sedative drugs and long continued submersion in hot water will only aggravate the negative conditions and make the underlying ailments more chronic and incurable.

**24. Mental Disorders.** At the first appearance of symptoms of mental disorder; the patient should be placed in an institution for natural healing, where surroundings and treatment are favorable for early recovery.
25. Nose. (a) Foreign Bodies in. (See "Ears," p.397.)

b) Nosebleed. Sniff cool water mixed with lemon juice. This has an astringent effect upon the capillaries. Compress the nostrils temporarily, throw the head backward, and avoid vigorous blowing of the nose. Apply cool compresses to the neck at the base of the brain. Repose on a chair or couch, perfectly relaxed, in a sitting position and remain that way until the bleeding ceases. Refrain from any movement of the body. Have someone else catch the running blood in a basin or cloth. This is the best way to facilitate clotting of the blood.

If this is not sufficient to stop the bleeding or if it should grow worse have small plugs of cotton or muslin inserted tightly into the nostrils. However, it must be remembered that the bleeding may be a form of elimination. It often occurs as a form of healing crisis and should, therefore, not be interfered with unless necessary to avoid excessive weakening and collapse.

26. Poisoning. (a) The first thing to be attended to in any case of poisoning, whether or not the exact nature of it be known, is to empty the stomach. This may be accomplished by the swallowing of large quantities of warm water containing the appropriate antidote, and by tickling the palate with the finger or a feather, thus causing copious vomiting. The washing of the stomach must be repeated several times. If mouth and throat are not burned, a rubber tube may be pushed down the throat into the stomach. By means of a funnel, warm water is poured through the hose until it overflows. The end of the hose outside is then suddenly, lowered below the level of the stomach and water siphoned out of it. This may be facilitated by having the patient assume a position prone upon the face during the draining of the stomach.

b) In emergency cases, mustard, common salt or powdered alum may be given as emetics in proportion of one teaspoonful of either to a glass of water. A lukewarm solution of soap in water is a simple and efficacious emetic. If no emetics are available, cold water should be taken freely and vomiting induced by tickling the throat.

After washing of the stomach, white of egg, milk, or sugared water should be given freely. They are soothing to the inflamed membranes and give the poisons something to work on. Blood warm enemas of normal salt solution (Sec. XVIII; No. 4. p.165) should be given repeatedly in order to eliminate the poison from the intestines. When the patient is strong enough bed sweat baths followed by cold ablutions will stimulate elimination through the skin.

c) In corrosive sublimate or other forms of mercurial poisoning, retained rectal enemas of milk or white of egg beaten up in warm water will help to neutralize the destructive action of the metallic poison.
d) In all cases, fasting, with dilute fruit juices, should be enforced until the system has eliminated the poison and the injured membranes of the internal tracts have been repaired. Where the latter have been severely burned, fruit juices may cause burning pain unless they are very much diluted with water. In the mild dilute form, they will antidote the destructive effects of the poisons.

e) So called antidotes are effective only when administered immediately. The general rule is, against acid Poisons administer water mixed with baking soda or fresh lime; other good antidotes are white of egg, rich milk or oil. These substances neutralize the acids.

f) Alkaline poisons must be antidoted with dilute vinegar, milk, white of egg and other albuminous substances which neutralize alkaline poisons as well as acid poisons by diluting them and giving them something to work on besides the tissues of the body.

g) Narcotic poisons like opium, morphine, belladonna, digitalis, poisonous mushrooms, ptomains, alcohol strychnine, etc., cause loss of consciousness, stertorous breathing, redness of the face, cramps and delirium. If the victim of poisoning is unconscious, artificial breathing must be resorted to (No. 3, p. 383), and the neck, chest and other parts of the body should be sprinkled with cold water. A brisk, cold saltwater rub is very efficacious in reviving the vital activities. As a stimulant administer small doses of strong black coffee.

h) Arsenic, phosphorus, Paris green, vitriol, carbolic acid, hydrochloric acid and lye do not as a rule cause unconsciousness, but give rise to violent pains in the oesophagus, stomach and abdomen, followed by choking and vomiting. Some of these poisons burn the lips, mouth, oesophagus and stomach; such burns may be treated with a solution of baking soda or powdered chalk. The treatment otherwise is the same as given for alkaline and acid poisoning.

In cases of poisoning a physician should be called in as soon as possible.

i) Ptomain poisoning results from eating putrefying or decayed meats, fish, cheese, ice cream or other animal food products. The usual symptoms are collapse, subnormal temperature and pain in the digestive tract. Nature generally tries to remedy the trouble by vomiting and diarrhoea. Both these forms of natural elimination must be encouraged by the swallowing of warm water in large quantities and by warm saltwater enemas. (Sec. XVIII, No. 4, p.165.)

The treatment of ptomain poisoning is very much the same as that of other forms of poisoning. The stomach and intestines must be emptied and cleansed as thoroughly as possible by induced vomiting and by saltwater enemas, as
described in the previous paragraphs. After that, the patient should drink copious quantities of fresh water mixed with acid fruit juices. This is much better than the taking of poisonous antiseptics.

While the temperature is subnormal, the bed sweat bath by means of the trunk pack or full sheet pack will promote elimination through the skin. When the subnormal condition is followed by inflammation and fever, cold packs and ablutions are in order and the treatment in general is the same as that for acute inflammatory conditions described under Sec. VII; p.75.

j) External Poisons. Poisons which affect the human body from the outside include poison ivy, poison oak and poison sumac. Poisoning by insects, snakes and rabid animals has been treated under other headings.

Poison ivy and the other poisonous plants above named owe their toxic qualities to an odourless, transparent oil found on the leaves, bark and twigs, which is insoluble in water. These poisons are powerful irritants. Contact of the skin with these poison plants causes insufferable itching, swelling and vesicular eruptions. In severe cases there may be vomiting, colicy pains, fever and delirium. Parts of the body or the entire cutaneous surface may be covered with eruptions.

The U.S. Department of Agriculture recommends the application of a solution of acetate of lead to be applied to the itching skin. This, however, is a powerful suppressant. While the eruption disappears rapidly under this treatment, it drives the plant poison plus the drug poisons into the system, and wherever these concentrate the morbid soil is prepared for chronic disease.

The poison in its outward symptoms, as well as its internal chronic after effects, resembles very closely the psora or itch taint. Its suppression in the acute stages broadens the scurf rim and frequently produces typical itch spots in the iris.

The best homeopathic antidotes in acute and chronic cases are Rhus tox., psorinum or sulphur. The homeopathic rhustoxicana is a trituration of the ivy poison.

The Natural Treatment. First it must be remembered that the itchy, burning eruptions represent Nature's, effort to eliminate the poisons from the system and that therefore it should not be checked or suppressed by any means whatever. The natural treatment includes, everything that will promote elimination of the poison through the skin and other organs of depuration. If water is immediately accessible, a good, thorough scrubbing of the skin with soap and water, or, if in the open, with sand, tufts of grass, or any other, scrubbing material may be sufficient to remove the poison before it will do any harm; at any rate it will greatly reduce the bad effects.

The preliminary cleansing should be followed as soon as
possible by a whole sheet pack or a bed sweat bath, and cold
Ablutions. This may be repeated several times if necessary, or
followed by partial packs. Otherwise, the treatment is the
same as for acute diseases. (Sec. VIII) Fasting and raw food
diet are especially beneficial. The cold packs, compresses and
ablutions are the best means for allaying the intolerable
itching and burning.

k) Antidotes for Acute Poisoning

By **Lead**: magnesia, soda or chalk water.

By **phosphorus**: thick liquid gum; white of egg; flour;
bread magnesia and cold water, for the purpose of enveloping
and isolating the poison. Do not give milk or liquids
containing alcohol or oily matter.

By **caustic acids, such as sulphuric, muriatic, carbolic or
nitric acid**: large quantities of soap, salt, chalk, limewater or
milk.

By **copper and verdigris**, frequently contracted by foods or
drinks prepared in copper vessels or by drinks from soda
water fountains when the copper has become exposed through
the away of the zinc lining: dilute white of egg; milk; water
mixed with honey or sugar.

By **Iodin**: starch or flour paste.

By **nitrate of silver**: strong saltwater solution; white of egg.

By **oxalic acid**: chalk or lime water.

By **strychnine**: meat burned to a cinder; decoction of acorn
coffee; tan or gall apple.

By **arsenic**: warm milk; sweetened water.

Scalds. (See Burns p.391)

27. **Seasickness.** The unpleasant sensations accompanying
this disorder are undoubtedly caused by a disturbance of the
center of equilibrium in close proximity to the, left ear, which
in turn affects the entire nervous organism and especially the
nerves supplying the digestive organs; causing intense nausea
and vomiting.

So far no effective remedy has been discovered for this
peculiar disorder. The following directions have in many
instances either prevented or greatly alleviated its Symptoms.

Those who intend to travel on the sea should prepare
themselves by a brief fast and light raw food diet. This should
be continued on board ship. The heavy, rich, greasy foods
served in overabundance on board of seagoing vessels
undoubtedly have much to do with bringing on the gastric
disturbance. The invigorating effects of a sea voyage might be
greatly enhanced by a prolonged fast beginning a day or two
before taking passage and extending for a week or more, according to the vitality and recuperative powers of the individual.

The best remedy, aside from these dietetic measures) and according to my experience the most efficient, is getting into harmony with the motion of the vessel or car. Many times outside patients have come to me saying they could not continue coming for treatment because the benefits were offset by nausea and vomiting caused by the shaking of the cars. I have instructed the sufferers from ear sickness as follows:

Instead of tensing yourself physically and mentally against the violent vibrations caused by the rolling of the vessel or car, relax completely. Do not oppose and fight the motions but let yourself go with them. A good way to do this is to hum a tune in harmony with the oscillating motion of the ship or car.

In many instances the very first trial of my remedy has given relief and after a few attempts no discomfort whatever was experienced. Those who are naturally immune to car or seasickness probably practice this form of relaxation and rhythmic adjustment unconsciously.

It is another proof of the truth and practicability of the maxim of the Master, "Resist not evil". Those who most fear this form of evil and tense themselves against it are most affected by it, While the person who thoroughly enjoys sea travel and to whom the rolling of the vessel is a pleasure naturally relaxes to it, enjoys the sensation, and therefore feels no discomfort.

28. **Shock** is characterized by collapse and frequently by loss of consciousness. It may result from excessive loss of blood or physical injury, or it may be caused by emotional depression resulting from mental and nervous excitation such as sudden fright, grief, anxiety or anger. In many instances it is the shock rather than the actual physical injury which causes death.

If the collapse is due to haemorrhage, this must be stopped as quickly as possible (see p.402). Cool behaviour and reassuring suggestions arc necessary to dispel fear and anxiety. The same tonic treatment must be administered as described under fainting, unconsciousness, etc., p.399.

**Signs of Life.** (See "Fainting", p.399.)

**Snake Bites.** (See "Bites", etc., p. 390.)

29. **Sprains, Strains and Dislocations.** Sprains and dislocations of joints must be attended to as quickly as possible by a competent physician, preferably a neurotherapist, osteopath or chiropractor. If, however, a physician is not immediately available and the injury results
in swelling, then cold packs must be applied to reduce the inflammation and to facilitate the adjustment.

If swelling, or pain, make it impossible to remove parts of the clothing or the shoes and stockings, these should be cut away with a sharp knife. The affected part must have absolute rest before and after the adjustment. Do not apply hot applications of any kind.

30. **Sunburns**, which are frequently the result of imprudent exposure in the sun-baths, are best treated by cold compresses and cold ablutions or by the olive oil and soda mixture.

31. **Sunstroke**. Sunstroke is caused by exposure to the direct rays of the sun in a heated atmosphere. Loss of consciousness is caused by the direct action of the sun's rays upon the brain and the cardiac and respiratory centers in the medulla.

   a) The onset is sudden. The most prominent symptoms are unconsciousness, pallor, feeble pulse and rapid failure of the heart and respiration. Death is common, recovery often only partial, leaving the brain permanently injured.

   b) Under the natural treatment few cases end fatally. The patient should be quickly undressed and cold water poured all over his body, also over the head. This should be followed by brisk salt water rubs; or the body should be wrapped in a wet sheet which must be kept wet by pouring cold water over it from time to time.

If collapse has taken place and vitality is greatly depressed, the patient must be put to bed and well covered with blankets so as to produce a warm reaction.

32. **Thermic Fever** may arise by night or by day through exposure to artificial or solar heat.

   Premonitory symptoms are malaise, nausea, diarrhea, giddiness, sleeplessness, after which the temperature rises quickly to 108 to 110 deg F. or even higher. Prominent symptoms are lividity of the face, dispnoea and delirium. These are often followed by coma and death within a few hours. It recovery takes place it is slow and incomplete.

   Cold, wet packs, followed by cold ablutions, must be applied. The drinking water should be cool and mixed with acid fruit juices. (See the usual treatment for acute diseases, Sec. VIII.) Under natural treatment few cases end fatally.

   **Toothache**. See Section XLIII, No.8, p.430.

33. **Transporting an Injured Person**. To lift or carry an injured person in the wrong way may cause permanent injury or even death; therefore, care fully examine the victim of an accident in order to ascertain whether he has sustained a fracture or serious internal injury.
First aid should be administered at once and on the spot; but if removal is necessary, a stretcher may be improvised out of a board, a door, bedspring, or anything else convenient for the purpose (Fig. 49, p.418). Care must be exercised not to drop the injured one. If a patient must be transported by carrying, the following methods will be found practical:

a) If the injured one can walk, let him put his sound arm around your neck and with one hand grasp his hand hanging down from your shoulder and with your other arm firmly support his body. (Fig. 46).

If the patient is unconscious, the following methods will be found most convenient:

b) You may carry the patient in an upright position, placing your right shoulder under his armpit and your right arm around his waist, his left arm back of your own neck and over your shoulder, taking hold of his left wrist with your left hand. In this way you can either help him walk, as previously described, or carry him entirely. (Fig. 46)

c) If an adult person is unconscious and requires immediate removal, it would be impossible for one person to carry him in his arms. In such an emergency, the pick-a-back method is the most practical. Stoop down and place the patient well up on your back; then pass your right arm around his right knee and with the other hand grasp firmly the wrist of his right hand drawn over your left shoulder. In this way he is in a safe position to be carried for a considerable distance and the weight is fairly distributed and balanced over your back and shoulders.
d) The third method of carrying an unconscious person is similar to (c), the only difference being that your right hand after passing around the upper part of the right leg of the patient, grasps his right wrist, drawing his right arm over your left shoulder and firmly across your chest, as illustrated in Fig. 47 above. This position leaves your left arm free for other employment, if desired.

e) If two persons are available for transportation they may support the injured one on their locked hands, while he places his arms about the necks of his carriers. (Fig. 48)

f) Fig. 49, illustrates an improvised stretcher. Two poles have been slipped through the sleeves and body of two buttoned coats. Other improvisations may be made by means of a board, door, shutter, mattress, etc.

SECTION XLIII

CARE OF THE TEETH

1. Disease of the teeth generally speaking, is the result of two causes: First, malnutrition, which causes deterioration and
destruction of the teeth from within; second, corrosion, caused by systemic acids and other corroding substances which attack, from without, the enamel of the crown and the hard covering of the neck and roots.

Dentists and books on hygiene deal almost exclusively with the last named factor. They have a great deal to say about the regular and thorough cleansing of the teeth, and of dental treatment, but seldom mention the influence of food materials, nutrition and constitutional disease on the condition of the teeth.

That this is not as it should be is proved by the fact that animals living on natural food, as well as savage races, and people who live in primitive surroundings and subsist largely on products of the soil not demineralized and devitalized by modern manufacturing processes, have splendid teeth and retain them to the end of life without tooth brush, dentifrice or the attention of a dentist.

The teeth of animals and humans who live on natural food well adapted to their needs, gradually wear off to the gums with advancing age but do not decay or fall out; neither are they troubled with abscesses, pyorrhea or other diseases produced by unnatural and artificial ways of living.

Regular examinations of children in our public schools disclose the fact that in spite of tooth hygiene taught in the schools and enforced in the homes, eighty-five percent or more are suffering from defective teeth. Of 1694 children examined in six clinics during the year 1913 by Dr. A. F. Foot, only eleven were found to possess normal teeth. Dr. Foot reported to the Second District Dental Society of New York as follows.

"The six-year molars of nearly every child were broken down wholly or in part. In many instances the molars were decayed to the gums. So extensive and far advanced were the defects that corrective treatment, even if it were applied, would have been of little value."

2. This almost universal decay of the teeth is caused:

1. by wrong food combinations;
2. by devitalized and demineralized food;
3. by the action of corrosive substances from within and without;
4. by the softness of the food materials and by their excessive heat and coldness;
5. by hereditary and congenital influences.

Examining these pathogenic factors separately we find that the ordinary diet customary in the home, hotel, restaurant and boarding house, consisting almost entirely of cooked foods, is excessively rich in starches, sugars, fats and proteins, but very deficient in the mineral salts. This is true of these foods even in their natural condition, as they come from the soil; but the
discrepancy between negative food elements and positive mineral elements is much greater after the cereals rice, sugar cane sap and beet sap have passed through the modern milling and refining processes. These leave the white flour, polished rice, decorticated corn products, pearled barley, corn starch, white sugar and corn syrup in a devitalized and demineralized condition. Together with the all-important mineral elements, the foods have been robbed also of their vitamins or life elements. What little is left of the vitamins is destroyed and dissipated by boiling, roasting, frying or fermenting.

Unnatural food combinations, which predominate in acid and pathogen producing negative food substances and are very deficient in the acid neutralizing and eliminating mineral elements or alkaline bases, produce excessive amounts of acids, ptomains, leukomains, xanthins and other pathogenic substances which corrode and tear down the outer enamel covering and internal dentine structure of the teeth.

The destructive effect of acids upon bone tissue can readily be demonstrated by submerging a piece of bone in hydrochloric acid. Within a few days the lime salts constituting the solid framework will be dissolved and abstracted, nothing being left but a soft cartilaginous and gelatinous mass. Submerge an eggshell in strong vinegar; within a few days it will be completely dissolved. In similar manner, acids in the blood and mouth fluids, and acids which form in decaying matter clinging to the teeth and in the hollow spaces between them, will gradually destroy the enamel and dentine.

Refined sugars act very much as do acids. Having been robbed in the refinery of their positive mineral elements, the remaining negative elements, hydrogen, carbon and oxygen, by chemical affinity leech the minerals from the bones and tissues, thus causing gradual decay.

The sturdy Scots owe their tall and large boned bodies to the highly mineralized cereal, fruit and vegetable products of their mountain valleys, the soil of which is enriched every season by the mineral wash from the rocky hillsides.

As long as they lived on whole meal barley bread and oatmeal porridge made from homegrown and home milled cereals, they had splendid teeth. During the last few generations, however, since they commenced to abandon their primitive foods for white bread, white sugar and devitalized breakfast foods, dentists have become more numerous among them.

3. Gingivitis and Pyorrhea. These ailments are so injurious, not only to the teeth, but also to the general health of the body, and they are increasing in frequency with such alarming rapidity that they deserve special attention.

Allopathic medical science declares that gingivitis and
pyorrhea, like all other inflammatory diseases, are caused by germs, and has vainly tried to cure these common ailments by the application of antiseptics and germ killers. We find that as usual the germs are secondary effects, that we must look for the true causes in other directions. These are:

1) Lack of exercise for the teeth and the connective tissues which hold them in place.

2) Inflammation of the gums, caused by hyperacidity of the system and other pathogenic conditions.

3) The corroding action of mineral deposits on the teeth.

Dr. Robert Aiston, a prominent Chicago dentist, who for twenty years has made pyorrhea a special study, says he is positive that lack of exercise for the teeth and the connective tissues which hold them in place, is the principal cause of pyorrhea.

In an interview I had with him lately on the subject, he said: "No man living has made a more exhaustive study of pyorrhea than I have, and I am convinced that the principal cause is the predominance of soft, mushy, cooked food in the customary diet of our American people."

The reasons with which he backs his opinions are very convincing. I shall condense them in the following paragraphs.

The roots of the teeth are held in place by ligamentous tissues and these remain strong and sound as long as they are subjected to normal strain from the push and pull exerted by vigorous mastication. When this ceases, as a result of the continuous consumption of soft, cooked foods, then the dental ligaments and other connective tissues begin to weaken and decay. Stagnation and putrefaction set up inflammation, this produces inflammatory exudates rich in calcareous salts and these in turn form seruminal calculi on the roots of the teeth, so called because these mineral encrustation's are precipitated from the blood serum. The doctor showed me a number of teeth which were thickly covered with these rough, earthy deposits.

I fully agree with Dr. Aiston that local stagnation, due to lack of exercise, is one of the primary causes of inflammation and destruction of the dental ligaments, but I believe that this is greatly facilitated and aggravated by pathogenic materials and disease taints in the circulation, and in the very beginning by mineral encrustation's on the surface of the teeth.

Elsewhere I have mentioned that in several cases pyorrhea entirely disappeared after the patients had been cured, by natural methods, of smallpox, gonorrhea, syphilis and other acute, eliminative diseases. Healing crises eliminated the disease taints; raw food diet reduced the "calcareous exudates" and scoured the teeth of slimy and earthy deposits.
deposits. In this connection I should mention that after the adoption of a raw food diet mineral deposits on the teeth at first increase. This is caused by the neutralization of large amounts of acids. But as the acidity, under the influence of alkaline diet, diminishes, mineral precipitation ceases, inflammation subsides, the encrustation's on the teeth are gradually absorbed and the gums have a chance to heal.

Pyorrhea, as well as other chronic ailments, can be cured only by restoring the entire organism to a clean, normal condition.

**Gingivitis.** The mineral deposits on the crowns of the teeth, usually light, gray in color, are commonly called tartar. Dentists speak of them as salivary calculi, because they are formed by earthy precipitates from the saliva. These tartar deposits may encroach under the borders of the gums, and this, together with slimy, mucoid accumulations, gives rise to inflammatory, destructive processes in the gum tissues. This is commonly called gingivitis. It is the forerunner of pyorrhea. The only difference between the two ailments is that in pyorrhea the mineral deposits form on the necks and roots of the teeth, and that these seruminal calculi, are blacker, harder and more destructive than the tartar on the crowns. The sharp earthy crystals help to corrode the dental ligaments, aggravate the inflammatory processes, and thus in turn increase the inflammatory exudate of calcareous matter. Filthy, putrefying matter could not accumulate around the teeth and under the gums if the food contained sufficient coarse, scouring material.

Thus it will be seen that the two causes, stagnation due to lack of exercise, and mineral precipitation due to hyperacidity of the system, seesaw in the causation of gingivitis and pyorrhea.

**The Rational Treatment of Gingivitis and Pyorrhea**

It is well enough to scrape from the teeth the earthy encrustation's which cause the gums to recede and to putrefy, but what good does this when the hyperacid condition of the system makes new deposits?

Many people have the idea that they can safely eat meat, eggs and large amounts of starchy foods as long as they consume with them plenty of the mineral salt foods, such as fruits and vegetables. As explained in Vol. I of this series, in Chapter XXIX, this is a mistake. The intake of too much starchy and protein food leads to the excessive production of acids and other pathogenic substances. Though these are neutralized by alkaline mineral elements, more earthy salts are thus formed than can be properly eliminated through the skin and kidneys. These salts collect on the teeth as tartar, or they may form deposits in the joints resulting in rheumatism.

**4. In order to prevent** these and a host of other acid diseases, it is not enough to adopt a vegetarian diet, but the
intake of vegetables, starches and proteids must be kept within normal limits. How to accomplish this I have explained under the heading of food combinations in Section 1, No. 10, pp. 23, 24.

Normal consistency of the food also has much to do with the preservation of the teeth. The perfect condition of the teeth of wild animals and of primitive man is partly due to the fact that they consume their foods in the natural raw condition, thus giving the teeth plenty of wholesome exercise by the gnawing, grinding and crunching of bones, grasses, raw cereals, fruits and nuts. While savage or primitive people cook some of their food, they use much more raw food than do their civilized cousins.

Cooked food, in which most of the vitamins have been destroyed, is much more prone to acid formation than live, raw food. Physicians and dentists frequently warn against acid and sub acid fruits "because they destroy the enamel of the teeth." This is a mistake. The live organic acids of fruits and vegetables, charged with vitamins, have not a destructive effect upon the bony structures as do the disease producing acids formed by abnormal food combinations and putrefactive processes. The malic and citric acids of the fruits are highly organized and help to dissolve the earthy deposits in the joints, and the tartar on the teeth. (See footnote page 434.)

Unless the diet contains liberal proportions of raw vegetables, fruits, roots and nuts, which are splendid natural scourers and cleansers, the teeth are bound to deteriorate and decay.

Even the teeth of cows become loose and fall out when the animals are fed continually on the soft, sloppy, devitalized and demineralized cereal offal of breweries and distilleries.

To begin the day and to end it with the munching of an apple or some other raw fruit or vegetable relish, is the best way to keep the teeth in a perfectly clean and sound condition.

Another reason why dentistry in civilized countries is one of the best paying professions, is the habit of swallowing food and drink, either very hot or extremely cold. Not infrequently the piping hot soups and other viands are washed down with ice water or immediately followed by ice cream, sherbet or other chilled desserts.

The sudden expansion and contraction due to contact with excessive heat or cold causes the enamel to crack and thus exposes the dentine of the teeth to the destructive activity of acids and other corroding substances.

When prospective parents have destroyed their teeth by unnatural practices, how can they expect to produce offspring with sound bones and teeth? When the blood of the mother is utterly deficient in the bone building mineral elements, is it any wonder that the new born comes into the world
handicapped for life with a dwarfed, defective bony framework? The formation of tooth substance begins in the embryo after the sixth week and continues all through gestation. This further reveals how important it is that the food of the mother contain sufficient amounts of the bone and teeth making elements. This is possible only when her diet includes an abundant supply of fruits and vegetables, hulls of grains and other mineral salt foods; classified under Group V of the food Table, page 33.

I have observed in many instances that when the prenatal structure and chemical composition of the teeth is abnormal, natural feeding after birth cannot always make good for the defective foundation. An imperfect, cankered Seed will not produce a perfect tree, even though the soil it grows in contains abundant nourishment.

5. Cleaning the Teeth. By the foregoing I do not wish to depreciate the importance of keeping the teeth in a clean and sweet condition by careful scrubbing several times a day, particularly in the morning and before retiring. If convenient it should be done after every meal.

However, we do not favor for this purpose the use of preparations containing poisonous antiseptics. These are readily absorbed by the tender tissues of the mouth and in time will cause trouble in the body. Practically all tooth powders, pastes and lotions sold in the drug stores contain such deleterious substances. These are not only decidedly harmful, but entirely superfluous because the best tooth wash is fresh, cool water made slightly acid with lemon juice. Brisk scrubblings of the teeth with this natural dentifrice will keep the gums and teeth in clean and sweet condition. This should be followed by rinsing the mouth with fresh water. The scrubbing should be done from above downward and from below upwards. This will tend to pull the gums over the teeth and to cleanse the crevices between the teeth from food particles and slimy accumulations.

Another good treatment is to dip the forefinger into cold water and give the gums, inside and outside, a good rubbing and kneading. Always finish by rinsing the mouth thoroughly with water as cool as the gums will endure.

If there is a tendency to the formation of tartar the teeth may be thoroughly scoured a few times a week with ground pumice stone, whiting or oyster shell, but this must not be repeated too often because it might injure the enamel.

It goes without saying that the teeth should be looked after by a competent dentist at least every six months, and that defects of any kind should be attended to promptly. Many a tooth can be saved by a timely filling, a well fitted crown, or good bridge work. These matters must be left to the skill of the dentist. The better he understands his art, the more economical will be his services in the long run.
6. **Foci of Infection and their Suppression.** The latest theory of medical science is that rheumatism and a number of other acute and chronic diseases are caused by germ infection from suppurating tonsils and adenoids, from abscesses in the teeth and ulceration and pyorrhea of the gums. These shortsighted deductions are the natural outgrowth of the germ theory and of the local and symptomatic conception of disease.

We find in our institutional work that the aches and pains of rheumatism, headaches and asthmatic spasms, etc., come and go, rise and fall in exact proportion to the increase and decrease of acids and other pathogenic materials in the circulation. I do not deny for a moment that the pathogenic materials in these foci of infection may start or aggravate acute conditions in other parts of the organism, but is it sufficient to suppress the foci of infection with antiseptics and surgical treatment? **The question is, what causes the foci of infection, the suppurating tonsils and adenoids, the abscesses in the teeth, the ulcerating gums and jawbones?**

Does medical science imagine that the suppression of these foci of infection with poisonous antiseptics and surgical operations solves the problem? Why cannot they see that this also is rank suppression and not Cure? Can a healthy body, endowed with pure blood, normal tissues and perfect mechanical structural alignment, develop such foci of infection? **What is the use of suppressing these symptoms of constitutional disease in one place and having them bob up at another place in more destructive form?** Of such nature are the great achievements of modern medical science.

7. **This latest craze** has led in innumerable instances to the pulling out of whole sets of teeth because one or more were abscessed or because of the presence of so-called pyorrhea, which frequently is nothing but a raw condition of the gums induced by encrustation's of tartar on the roots of the teeth. I meet almost daily with people who have been robbed of sound teeth, sometimes of entire sets, on the assumption that it would cure their rheumatism or other constitutional diseases. To their sorrow they find that the cruel sacrifice has brought no relief so far as their chronic ailments are concerned.

Such criminal experimentation is on a level with tearing out sound ovaries with the idea of curing epilepsy or other chronic diseases. I have known of a number of such uncalled for mutilations. In no instance has the unnatural treatment benefited the patient; it has only served to aggravate the chronic ailment and to hasten physical, nervous and mental breakdown.

The constant suppression of symptoms of disease by drug poisoning and surgical mutilations creates chronic invalidism, hereditary disease, and defectives. Is it not more rational to put the system, through natural living and treatment, in such a pure and wholesome condition that it cannot develop inflammation and suppuration of the tonsils, teeth, gums and
8. Toothache. One of the most excruciating tortures that man inflicts upon himself by wrong living, is the toothache. All the causes I have enumerated and described help to create it, and avoidance of these causes is the best prevention.

There are two general types of toothache, the acute inflammatory, accompanied by heat and swelling, and the cold neuritic or neuralgic.

a) The acute inflammatory may be due to congestion and irritation of the blood vessels and nerves of a tooth or row of teeth by systemic poisons, in the same manner that inflammations arise in other parts of the system as the result of pathogenic obstruction and irritation. Acute inflammation may arise when the nerve of a tooth becomes exposed through decay of the bony structure. In that case the attention of a dentist may become necessary. But care must always be taken not to cover decaying particles with a filling or crown. The parts to be covered must be carefully cleansed of all materials that might cause further putrefaction.

b) Treatment. The acute inflammatory toothache is best treated by retaining cool or cold water in the mouth until it warms up, when it should be spit out and replaced. At the same time cooling compresses or packs should be applied to the cheek on the affected side. The pack as usual consists of a piece of muslin, folded from three to six times, and wrung out in cold water. The cold compress is then covered by one or several folds or dry flannel or woolen cloth. The compress or pack may be kept in place by one of the bandages described on page 390.

An acute congestive toothache may be greatly relieved by gentle downward massage movements along the veins and lymphatics in the neck. Thorough drainage of these vessels will do much to relieve the congestion in the affected parts. While giving the massage movements, also use your mental power to combine with the mechanical treatment the magnetic effects. Osteopathic, chiropractic and naprapathic treatments prove very effective in many cases.

In serious attacks the local water treatment may be reinforced by a whole sheet pack, bed sweat bath, or body or leg packs followed by cold ablutions (Sec. XV, p. 147). During the night the sufferer may at intervals take a cold rub and go under the bed covering without drying. All these water applications draw the blood away from the congested area into the surface and thus relieve the local congestion and excruciating pain. They also promote the elimination of the pathogenic materials which are the primary cause of the trouble.

If acute inflammation within and around the teeth were always treated in this way it would seldom come to the formation of acute or chronic abscesses. The pathogenic
materials would be absorbed and eliminated immediately.

Of equal importance with the water treatment is fasting. From the first appearance of a toothache, absolutely no food should be taken until it has ceased entirely, and even then the fasting should be continued for a day or two in order to clear up the constitutional condition which caused the local inflammation. Fasting alone in many instances has cured the severest toothache.

I would **warn strongly against the use of poisonous pain killers.** They only serve to paralyze the nerves and do not in any way remove the underlying causes of the trouble. They add drug poisons to disease poisons and thereby accelerate destruction of the teeth and the gums.

c) Neuritic Toothache. This type of toothache is not accompanied by great heat and swelling as is the inflammatory kind. It is usually caused by the exposure of a nerve, or by the irritating effect of some systemic or drug poison. If caused by defects of the teeth and by exposure of a nerve, proper dental attention is of course indicated.

This type of toothache is much more stubborn and does not yield to treatment as easily as does the acute inflammatory kind. Cold water, magnetic and manipulative treatments give but momentary relief. The reason is that the pain will continue or will return at intervals until the poisonous irritant is removed or until the nerve is killed or protected. Sometimes the jaw bones and cheek bones are more affected by these neuritic toothaches than are the teeth themselves. This is usually due to the action of some irritating poison.

d) Treatment. In these cold, persistent forms of toothache, hot applications sometimes give better relief than the cold applications, though the relief is temporary.

A remedy worth trying when cold treatment fails, consists in the application of a muslin bag partly filled with hot salt and held in place by a bandage. The salt should be as hot as it can be endured.

The only way these neuritic toothaches can be permanently cured is by eliminating the poisons which are at the root of the trouble.

In many cases we have found mercury, iodine, arsenic, quinine, or other drugs to be the real cause of the disturbance.

Elimination of these hidden enemies can be accomplished only by thorough systemic treatment and natural methods of living.

Many dentists are in the habit of using large doses of iodine, arsenic or other powerful poisons for killing the nerves. They should be warned not to use any more of these destructive poisons than is absolutely necessary. If the work
can be accomplished without using them at all, so much the better.

I would also warn strongly against amalgam fillings. The amalgam or silver filling, so called, contains about 50% of mercury. Acids in the blood and in the fluids of the buccal cavity have a tendency to dissolve the mercury and to create bichlorid of mercury and other mercurial salts which will accumulate in certain parts of the body for which they have a special affinity, particularly in the brain and spinal cord. I am aware that such warnings are pooh-poohed and ridiculed by many dentists, but practical experience tells a different story. The blackening of the teeth indicates formation of mercurial salts. In numerous cases, we have observed pronounced symptoms of mercurial salivation, such as metallic taste in the mouth, ulceration about the necks of the teeth, fetid breath and abnormally increased flow of saliva, which did not disappear until the amalgam fillings were removed from the teeth and replaced by gold, or porcelain. Gold filling, whenever it is practicable, is undoubtedly the best of all.

I know skilled dentists who have discovered these facts for themselves in the course of practice and who have discontinued the use of amalgam fillings on this account.

Of late I have met with several cases of paresis which showed distinctly the sign of mercurialism in the iris. Inquiry revealed the fact that these patients were dentists who for many years had been in the habit of mixing the amalgam and alloy in their bare palms. Mercury had thus been absorbed and was responsible for the destruction of brain substance.

Referring to statements made in section XLIII. 1. In the last paragraph I call attention to the fact that acids act differently on dead and living tissues. The hydrochloric acid secreted by the stomach in normal solution does not affect this organ injuriously, while it readily decomposes the stomach of a dead animal. The same principle holds true in relation to the action of fruit acids on dead and live teeth.

SECTION XLIII

WHY GROW OLD?

"What a question," you exclaim. "We grow old because we cannot prevent it; because Nature has decreed it so."

Of course we shall grow old in years but if we live in harmony with Nature's laws we need not grow old in mind or heart nor lose our physical energy and our alertness and suppleness of body and mind long before the expiration of our allotted time. While growing older in years we should grow younger and more robust as far as our intellectual, emotional, moral and spiritual qualities are concerned.

As regards longevity and the possibility of retaining our
youthful qualities to very old age, we meet with two extremes of opinion. Many mental scientists and new thought people tell us in their lectures and writings that it is not impossible to achieve immortality and perpetual youth in the physical body on this earth plane; that we die long before our time because we imagine we must; that a short-lived existence was necessary for animals and human beings in the early stages of evolutionary development, but that now since the physical body has become more perfect the necessity for dying has passed away and that as soon as we can exterminate the old age and death thought which has become race habit, the "last enemy" will be vanquished and immortality and perpetual youth in the flesh will become the common heritage of human kind.

The majority of mankind entertains an entirely opposite and somewhat pessimistic opinion as regards longevity and the preservation of youth. They are convinced that growing old and decrepit, that losing the enthusiasm, beauty and efficiency of youth is inevitable. They argue that growing old or dying young, health or disease, depend upon heredity, environment, colds, drafts, germs and other accidental circumstances over which we have little or no control. One prominent physician recommended the chloroforming of people over sixty years of age. These two opposing views were brought home to me quite vividly some time ago, while attending a lecture by a well-known mental scientist. His subject on this occasion was "Perpetual youth".

In alluring language, scintillating with plausible argument and beautiful metaphor, he proved to his own satisfaction the possibility of perpetual youth and life ever lasting in the physical body. After the audience had given fervent expression to its approval of his lofty idealism, an elderly gentleman in the audience arose and delivered his views on youth and longevity in a pessimistic wail that was taken in shorthand by a stenographer present in the audience.

"This subject of perpetual youth as put forth by our speaker is a beautiful theory. It is a wonderful theory, but I am very clear that it does not work out in life. I do not believe there is such a thing as perpetual youth. It is an ideal belief. You cannot by any process known to human science or human ingenuity turn back the wheels of time or stay them in their revolution."

"This fountain of perpetual youth old men have sighed for, old women have prayed for, and in search for it from time immemorial young women have appropriated their husbands wages and poured their money into the cash box at the drug store; but they have never yet found it."

"It is true that by right thought and right action you can probably postpone old age, but you can postpone it only to a very limited degree. The speaker stated that seventeen hundred people in the United States had reached the age of one hundred years, but he did not tell you how many of them
are paralyzed, how many of them are palsied, how many are more dead than alive.

"He tells you that with advancing age the arm of the blacksmith grows stronger. This is true for a certain time, but its strength reaches its zenith, then it grows weaker and weaker until it hammers no more. Young man, you cannot turn back the wheels of time and you cannot stay their revolutions. The time that is past is laid to rest in eternal sleep; it is buried in the mysterious realm of oblivion.

"Time robs the bridal wreath of its beauty. Time writes wrinkles upon the brow of the aged. You may wreath, garlands and place them around the brow of youth, but the onward march of time sees them wilt and mingle with the dust.

"The birds that sing so sweetly will return in the spring. The flowers will return and bloom again, but, ah, my friends, youth is gone. It is past forever. It never returns, but age is real and forever-perpetual youth is no more than a beautiful dream."

As regards the possibility of life everlasting on this earth plane, I for my part would gently but firmly decline it. The idea of living in the same old place forever and forever is not attractive to my mind. I imagine in time it would become too monotonous.

To me, life is a great school; a school of personal effort for the development of our latent god-like faculties, capacities and powers. This school takes in all there is in the sidereal universe. Its course in length of time is eternity; its classrooms and laboratories are the solar systems and their planets. Whenever we have learnt all there is to learn; all there is to be acquired of knowledge, wisdom and experience in this great school of life, then it will be time for us to die. The only death I know of is stagnation and retrogression. Life is growth; growth is change, continual, perpetual change—senescence and rejuvenescence, as science calls it. Death is only a phase in this continuous process of change.

The majority of mankind look upon death as the greatest evil in life. They think of it with despair and terror. Some commit suicide because they are afraid to die—a strange paradox, inspired by fear, fear of something that is in reality the greatest of all blessings, the birth into a new and brighter world with new life, new youth, new and broader possibilities, after we have acquired all there is to be learned in one brief earthly pilgrimage.

Why grieve for the loss of loved ones who have made the great transit before us? Shall we not be glad to meet them when we arrive on the other shore? If we had to travel on a long journey to a foreign country, wouldn't we be pleased to meet with friends among strangers in a strange land?
Life on earth is only the kindergarten in the great school of the universe. Even the greatest and wisest of men that live on this earth are only in the lower grades of the great Cosmic University. Why should we fear to pass on? Nobody would like to remain in the primary grades all his life when there are so many more interesting, useful and beautiful things to be learned in the higher grades.

One New Thought philosopher argues that immortality in the flesh, or at least a prolonged term of life on this earth, is necessary in order to acquire all there is to be learned and experienced in this beautiful world of ours and in order to permit the law of compensation to work out the great chain of cause and effect.

How much more reasonable and beautiful than this idea of continuous existence on earth is the philosophy of Karma and reincarnation of the ancient wisdom religion. Is it not better to have the arduous training of earth life alternate with vacations in the spirit land, and to return oblivious of previous existence's with their depressing burdens of errors, sins and sorrows? Thus death on one plane of life becomes birth into another, and vice versa.

In this continuous change from the old age of one life to youth in another life, lies for me the true solution of rejuvenescence, of immortality and of perpetual youth.

If we look upon life from this higher and brighter viewpoint, how can we grieve at growing old? How can we fear death? Those who are in conscious touch with life on the spiritual planes tell us that beings of high spiritual development appear in a condition of youthful maturity, combining the wisdom of millenniums of spiritual and celestial existence with the beauty of perpetual youth. It is not knowledge, wisdom and experience that causes premature senility and death, but wrong thinking, feeling and doing. Aside from unnatural physical habits of living, nothing promotes senile decrepitude like fear of disease and death, bred through ignorance of life's great laws.

He who looks at life from the higher and brighter viewpoint enjoys advancing life in ever greater serenity of soul and happiness of spirit. He rejoices in ever greater expansion of mind and deeper understanding of life's mysteries. He is justly proud of every year added to a life of usefulness to himself and to his fellow beings. Such a one has only pity for the pessimist's wail previously recited. Such gruesome thinking and feeling is the very essence of black magic that ages and stiffens the body and pencils wrinkles on the brow.

To grow younger as we grow older, we must practice white magic. The body is an electrotype of our mental images. Physical matter convolutes to the mental and psychical or soul pattern. "As a man thinketh in his heart, so is he," or as Gautama Buddha expressed it, "I am today what my past
thoughts and feelings have made me."

See yourself in your mind's eye as always beautiful, vigorous and active, as in the prime of youth, for "A man is never older than he feels, and a woman never older than she looks." "But", you ask, "how shall we keep our looks young?" That is simple. Bathe daily in the sparkling waters of serenity of mind and of cheerfulness and in the milk of human kindness. Learn how to relax completely in body, mind and soul and never entertain discordant and destructive thoughts and emotions.

**Physical Causes of Senescence**

Mental magic alone, powerful as it may be, is not sufficient to prevent the aging of body and mind. We must also live in harmony with the laws of the physical. No matter how good a watch you have, if you allow it to fill up with dust, dirt and corroding acids, it will soon lose time and finally stop entirely. This is exactly what happens to the human clock when it "grows old".

As philosophy has two divergent opinions concerning the prolongation of life, so has physical science two theories concerning the causes of senescence or senile deterioration. According to one of these theories, the animal and human being is endowed at birth with a certain amount of vitality, or with a certain momentum of vital force. When this is gradually spent in course of time our powers begin to wane; as a result of lowered vitality the vibratory power to expel waste declines; blood and lymph vessels become obstructed, joints stiffen, brain and nerve matter hardens and we grow old and decrepit.

Certain facts in Nature favor this viewpoint. Even under the most favorable conditions in the freedom of Nature animals live only to a certain age limit. Each species and family of creatures seems to have its own allotted lifetime or age limit. When this limit is reached they suddenly decline and die. I say "suddenly" advisedly. They do not spend a third or a half of their lifetime in getting old and in dying like the average human being. They retain their full vigor and beauty of form almost to the end of life. It is of rare occurrence that a hunter kills an animal that is found to be diseased or deformed. Among antelope, deer and elk the oldest bucks are usually the leaders of the herd. In order to maintain their supremacy they must fight and vanquish their younger rivals.

So human beings when living the natural life, physically, intellectually, morally and socially, will reach the no limit fixed by Nature for the human species in full possession of their faculties, capacities and powers, and will depart from life peacefully. Death will be as painless and sweet as sleep. I believe that in higher reaches of evolutionary development yet to be attained by mankind, the transition from earth life into spiritual life will not mean the passing "through the valley of the shadow" but that human beings will make the transition in
full possession of their waking consciousness.

The opposite theory advanced by physical scientists as regards the causes of senescence, postulates that vital energy is generated by the cells, tissues and organs of the body, and that as these with advancing age deteriorate and disintegrate, vital energy ceases to be generated and the constituent elements of the body become unfit to carry on the vital activities.

Natural Therapeutic philosophy teaches that the physical body is an instrument for the manifestation of the great life force which is divine life, intelligence and creative power. God or Nature evidently does not intend us to live on this earth forever in one continuous stretch of life and therefore has wisely limited the supply of vital force as well as the durability of the physical body in accordance with the laws governing incarnation and reincarnation on the physical and spiritual planes of life.

As before stated, even the healthiest animals living in the most congenial surroundings in the freedom of Nature do not much exceed their allotted span of life, nor do they fall much below it. As a rule, the longer the period between birth and maturity, the longer the life of the animal.

All the different families of mammalia, when living in freedom, live closely up to the life period allotted to them by Nature. Man is the only exception. It is claimed that according to the laws of longevity his average length of life should be considerably over one hundred years, while according to life insurance statistics the average is at present about forty years. This shows an immense discrepancy between the possible and the actual longevity of man.

Even this brief average span of life means for the majority of mankind little else than weakness, physical and mental suffering, premature senility and death. Visiting physicians of the public schools in our large cities report that seventy five per cent of all school children show defective health in some way. Diagnosis from the eye proves that the remaining twenty five per cent are also more or less affected by hereditary and acquired disease conditions. Christian Science says, "There is no disease". Nature's records in the iris of the eye prove there is no perfect health.

These established facts of greatly impaired longevity and universal abnormality of the human race would of themselves indicate that there is something radically wrong somewhere in the life habits of man, and that there is ample reason for the great health reform movement which was started about the middle of the last century by the pioneers of nature cure in Europe and which has since swept, under many forms and guises, all portions of the civilized world.

When people in general grow better acquainted with the laws underlying prenatal and postnatal child culture, natural
living, and the natural treatment of diseases, human beings will approach more closely the normal in health, strength, beauty and longevity.

However, to reach this ideal of perfect physical, mental and moral health, succeeding generations will have to adhere to the natural ways of living and treating their ailments. It cannot be attained by the present generation. Those enthusiasts who claim that they can, by their particular methods, achieve perfect health and live the full term of human life are destined to disappointment. We are so handicapped by the mistakes of the past that the best which most of us adults can do is to "patch up", to attain a reasonable measure of health and to approach somewhat nearer Nature's full allotment of life.

Growing old consists in the accumulation of waste and morbid matter, earthy deposits, destructive acids and alkaloids, causing the stiffening and hardening of joints, bones, veins and arteries and the gradual loss of physical and mental energy.

Do you ever stop to think how this clogging and corroding of the wheels of life is promoted and accelerated by wrong habits of eating and drinking? Food chemistry as taught by the school of Natural Therapeutics clearly shows that excessive use of starchy and proteid foods is the most prolific cause of disease and of premature old age. These classes of foods create in the body a large variety of destructive acids, ptomaines and alkaloids, such as uric acids, sulphuric acid, oxalic acid, indican, xanthins, creatin, etc.

Flesh foods especially favor these morbid accumulations because they are already saturated with all the waste products of the animal carcass. The poisonous xanthins of coffee and tea are almost identical with uric acid. While at first they over stimulate the organism, the second and lasting effect is to benumb and paralyze heart and nerves and to retard elimination, thus causing directly and indirectly retention and accumulation of waste matter in the body.

For these reasons, we of the Natural Therapeutic school realize that the only way to keep the system pure and sweet and its vibratory activities vigorous and harmonious is to reduce in the daily dietary the allowance of starchy and proteid food and to use a larger proportion of fruits and vegetables whose alkaline elements tend to dissolve and eliminate the acid crystallizations and deposits in the tissues.

This becomes more imperative as we grow older. A young and growing body, physically active in play and sport, needs a great deal of sugar and of proteid to furnish fuel and to feed and repair the rapidly growing and changing cells and tissues.

When we pass the meridian of life, growth ceases; there is much less physical activity and therefore much less need of starchy, fatty and albuminous elements. Therefore, as we advance in years these foods should be reduced in amount and
replaced by the dissolving and eliminating fruits and vegetables, but conventional habits and the doctor's advice usually favor the opposite course.

"You are growing older," says the doctor; "you must have plenty of strengthening foods—meats, eggs, fish, fowl—and you need some stimulants. Coffee or tea is all right and an occasional glass of beer or of "Duffy's Old Malt" won't hurt you, either."

Frequently a patient tells us, "All the young people in our house are now living on the natural diet, but you know father and mother are growing old and they must have their soup and meat, their coffee and beer; in order to keep up their strength."

Reverse the prevalent ideas on hygienic living and you are just about right; so in this regard the very opposite policy should be adopted. The older we grow, the less we need of the heavy, clogging foods and the more of the light and purifying.

The majority of people eat too much anyway. Habitual stuffing practiced through many generations has made it second nature. Many consume the best part of their available vital force in endeavoring to digest and eliminate superfluous quantities of food and drink. Every ounce of food in excess of actual need wastes vital force.

A Roman proverb said: "Plenus venter non studet libenter"—a full stomach does not like to study.

Vital energy required to remove useless ballast cannot be transformed into physical or mental energy. Vital force is a primary force. It cannot be eaten. It comes from the source of all life and is independent of the physical body just as electricity is independent of the bulb which it fills with light. Food can only furnish fuel material for the flame of life and keep the human organism in such condition that vital force can manifest itself in it and through it. If food and drink could give life they should prolong it indefinitely; in that case the glutton and drunkard would live the longest, but common experience teaches us that the man temperate in all things best preserves his physical and mental vigor and lives the longest.

The beauty about all this is that nature cure philosophy does not confine itself to visionary theorizing, but that it "delivers the goods". If we can take all sorts of chronic incurable diseases and within four or five months or a year's time work a wonderful transformation and actually cure the majority of such patients and give them a new lease on life, why should it be impossible to prolong life to its natural limit and to retain to the last, unimpaired, our faculties, capacities and powers of body, mind and soul?

How much greater would be the possibilities for health and longevity if human beings were brought into life and treated in the natural way from the beginning; that is, from the time
of mating and conception through the prenatal and postnatal periods and on through youth and maturity. Within a few generations the offspring of such Natural heredity would live the full allotted time of a hundred and fifty years in perfect health, strength and beauty, thoroughly efficient in the business of life, a true aristocracy not of vitiated, degenerated blue blood, but of pure red blood of perfect buoyant health.

Many of our young people are now beginning to carry out this great plan for the creation of a better, healthier and more beautiful humanity. They are seeking partners among those who have been educated and trained in the ways of natural living. If the offspring of such naturally mated couples do likewise and select their partners in turn from among those who are the product of natural heredity, what a different humanity will inhabit this earth within a few generations.

This is not vain dreaming. It is marvelous how the youth of this country have taken hold of these new ideas; how many are adopting the new life in harmony with Natural Therapeutic philosophy, physical culture teachings and other Systems of natural living and healing. Quite frequently young couples come to me, saying, "Doctor; we want to get married; but before we do, give us a thorough examination and, if necessary, we intend to take a course of treatment in order to put our bodies in right condition for the great responsibilities of matrimony and procreation."

What wisdom—what a glorious promise of a better; healthier and happier humanity!

**How to Grow Younger**

Keep in the light—cultivate the air and light bath—nothing sweet or beautiful grows or ripens in the darkness.

Avoid fear in all its forms of expression; it is responsible for the greater part of human suffering. The only thing to fear is fear.

Don't live to eat but eat to live. The cook is the chief executioner of King Death.

In the morning do not say, "I am another day older and so much nearer the end"—say "I feel one day younger."

How can we grow old with all eternity before us! The wise men tell us that in the higher life the good ones always appear in the vigor and beauty of mature manhood and womanhood.

What difference makes it if this old suit of ours grows a little shabbier? We shall soon wear a new and better one.

Be as a child, live simply and naturally, steer clear of too much money and too much worry.

Cultivate the spirit of content; nothing ages the face and furrows the brow so quickly as nagging discontent, suspicion
and jealousy.

Before going to sleep, throw off all the cares and anxieties of the day and attune your physical, mental and psychical vibrations to harmonies of rest and peace and love.
PART V

SECTION XLII

FIRST AID IN ACCIDENTS

A person in possession of a clean, healthy, supple body as a result of natural living and treatment, is not nearly as likely to suffer injury from accidents or to develop chronic after effects resulting from them as one whose body has lost its natural elasticity, keenness of sensory organs and recuperative powers through unnatural habits of living and the resulting Pathogenic conditions. This is well known to physical examiners for accident insurance concerns. When a body is in a pathogenic condition, a slight scratch may be sufficient to cause serious blood poisoning or a bruise or fracture may result in necrosis or tumor formation.

Natural methods of treatment are as efficient in giving first aid as in the treatment of acute and chronic diseases, though it may be necessary in serious cases to procure without delay the aid of a surgeon or trained osteopath, chiropractor or neurotherapist in order to examine for internal injury or to correct sprains, dislocations, fractures or other mechanical lesions. However, any layperson possessed of ordinary intelligence and common sense can apply the first aid methods herein described.

In many instances, natural treatment applied in time will greatly ameliorate the suffering and establish the best possible conditions for perfect recovery. The old time drug treatment which was held to be indispensable in cases of accident is as useless and harmful under these conditions as in the treatment of acute and chronic diseases. Much experience in all kinds of emergencies has convinced me that this is true.

In case of an accident it is of primary importance not to become excited and thereby to lose presence of mind and self-control. It is only by remaining cool and relaxed that one can think clearly and decide quickly upon the best course to pursue.

In first aid as well as in acute diseases the quickest and best results are obtained by hydropathic and manipulative treatment. It is, therefore, necessary for the student of emergency work to thoroughly study the methods and applications described under those headings. In order to facilitate quick and ready reference I shall treat the various occasions for first aid in alphabetical order.

1. Alcoholism. Acute alcoholism may result in complete collapse and stupor. It has frequently happened that a person
found in an insensible condition in a public place is mistaken for a drunkard in a stupefied condition, and carted off to a police station, when in reality he is suffering from injury, a stroke of apoplexy, sunstroke, heat prostration or from some other serious physical disorder. In order to prevent such mistakes, which might easily result in the death of the sufferer through lack of proper care, it is necessary to smell the breath, which, in cases of alcoholism, will immediately tell the story.

a) The best treatment for alcoholic stupor consists in brisk cold rubs, followed by good massage and neurotherapy treatment, calculated to stimulate and to revive the activity of the brain and nervous system. An enema of a warm, normal salt solution is also very beneficial. When the patient revives, half a cup of black coffee with lemon juice will act as a mild heart stimulant.

b) Delirium Tremens is a form of acute mania brought about through temporary paralysis of the brain centers which are the seat of reason, will power and self control. The lower animal emotions are running amuck and in many such cases various forms and symptoms of abnormal psychism prevail. The horrible experiences and visions of people in this condition are not always delusions and hallucinations but frequently are the result of clairvoyance and clairaudience on the lowest spiritual or astral planes, the purgatories and hells of the theologians.

The various phases of abnormal psychism are fully treated in Volume IV, Eugenics. This abnormal functioning of the sensory organs of the spiritual body is brought about through the temporary paralysis of the sensory organs of the physical body;

In order to prevent complete collapse it may be necessary to give at increasing intervals and in decreasing doses, alcoholic liquor, coffee, tea or other light stimulants to revive and strengthen the animal magnetism of the physical body. Tincture of passiflora administered every two or three hours in from ten to twenty drop doses is a good non-poisonous vegetable tonic. Meat broth, Tartar sandwich and other flesh foods may be given until the patient has recovered from the abnormal psychic condition.

The hydropathic treatment consists of cold rubs and cold douches, wet packs and cooling sitz baths. Massage and neurotherapy treatment is of great importance in such cases, not only for its mechanical but also for its electromagnetic effects.

Epsom salt or sea salt rubs also have a positive magnetic effect upon the system. Hot bathing, bromides and other "sedative" measures only aggravate the condition because they have a weakening, benumbing effect. Those who apply such sedative remedies forget that delirium tremens and other maniacal conditions are the result of weakness, exhaustion, and of a benumbed and semi-paralyzed condition of the brain.
and nervous system, and that, therefore, tonic, energizing treatment is required instead of benumbing, sedative remedies and applications.

When the patient has recovered from the effects of acute alcoholism he should undergo thorough systematic natural treatment in order to eradicate completely the craving for alcoholic stimulants. We have treated and permanently cured many victims of the drink habit who had undergone all sorts of drink cures without permanent results. As drug cures for the drink habit work on the principle of "poison kills poison". It is Beelzebub against the devil. While drugs may temporarily kill the craving for alcoholic liquors, the results thus obtained are not permanent. As the effects of the drug treatment pass off, the old craving returns and the drugs themselves have a weakening and deteriorating effect upon the system. Such Cures do not influence the moral nature.

Natural treatment with its "back to Nature" life, its pure food diet, and its educational influences through daily lectures and suggestive treatment, arouses higher ideals, strengthens will power and self control, and thus overcomes in a natural way the desire for alcoholic stimulants as well as habit creating drugs. It accomplishes this, not by the introduction of other poisons but by the purification of the organism and by the presentation of higher and purer ideals. One who, after such physical, mental and moral regeneration, has tasted the sweetness of the natural life will never again crave the gross deceptive gratification afforded by indulgence in alcoholic liquors and habit-forming drugs.

Strict adherence to a natural regimen for three or four months will take away all desire for alcoholic or drug stimulation. Patients have confessed to me that they did not backslide on account of an irresistible craving, but through careless surrender to temptation. Self control must be strengthened by educating the moral nature. Antidotes. See Poisoning, no 26.

2. Apoplexy. Apoplectic stroke and the resulting paralysis are caused by the breaking of one or more blood vessels in the brain. If the hemorrhage occurs in the right brain hemisphere, the left side of the body will be affected by paralysis on account of the crossing of the nerve tracts in the medulla and spinal cord. If the hemorrhage occurs in the left brain half, the right side will be affected. The extent of the paralysis depends upon the amount, of damage done to the brain centers in the area affected by the hemorrhage. The breathing is labored and stertorous, the face is flushed and purple in color, the features are twisted and drawn to one side, the pupils of the eyes are usually dilated.

a) The head and shoulders should be slightly raised. Quick, cold salt rubs followed by stimulating manipulative treatment will draw the blood away from the brain into the surface and extremities. A lay-person can give the extremities and fleshy parts of the body a good, thorough kneading, rubbing and
b) Wet packs applied to the body and, the extremities will draw the blood away from the congested brain area. A warm normal salt enema (Sec. XVIII, No.4) will help to establish normal circulation. A hot mustard bath applied to the feet or, better still magnetic treatment (p.397) will divert the blood into the lower extremities.

c) After consciousness has been restored, the patient must undergo thorough, systematic natural treatment in order to eliminate from the system the, pathogenic materials which have caused high blood pressure and the hardening and occlusion of the blood vessels in the brain and all through the body, and which brought about the hemorrhage and resulting paralysis. No alcoholic or drug stimulants should be given because they increase blood pressure to the brain.

d) In cases of concussion of the brain, apoplectic stroke, or of hemorrhages from the lungs or stomach, the patient must not be transported in a vehicle because the jolting might aggravate the condition. The sufferer must be carefully carried on a stretcher.

Of the many patients we have treated after a first apoplectic stroke, not one, as far as I can remember, has suffered from a second attack, provided of course there has been careful adherence to natural ways of living.

3. Artificial Respiration In many kinds of accidents, such as drowning, strangulation, asphyxiation by poisonous gases, and in serious cases of fainting and stupor, it may be necessary to resort to artificial respiration in order to restore normal breathing. There are several good methods for this purpose.

a) Quickly remove the clothing from the upper part of the body; lay the patient prone upon his stomach, place a small wad made of clothing or any other material at hand, under his forehead in order to elevate nose and mouth sufficiently to allow free breathing.

The operator knees athwart the legs of the sufferer and places his spread hands on both sides of the small of the back and then exerts gentle but steady pressure, thus compressing
the lower ribs and chest; he then gradually releases the pressure, allowing the lungs to fill with air. This alternating compression and relaxation of the chest must proceed at the same rate as the normal tempo of breathing, which is about fifteen breaths to the minute in adult life and a little more than this in childhood. With adults, therefore each complete movement in artificial respiration should consume about four seconds including expiration and inspiration, while in children it should consume about three seconds.

b) The same method may be applied while the patient is lying on his back. Make a roll of clothing and shove it under the small of the back so that the head lies lower than the chest. Then kneel astride of the hips, place both hands, fingers spread as far as possible, on the lower ribs below the nipples of the breast and count slowly one, two, three, four; while counting one and two, compress the lower chest gently but firmly and relax the pressure while counting three and four. Continue this alternating compression and relaxation until normal breathing commences (provided life is not extinct). A sudden trembling and heaving of the chest and flushing of the face will indicate when natural breathing commences. While compressing the chest, the operator should at the same time apply strong vibration. This is accomplished by vibrating the hands loosely and vigorously from the wrist joint. The slow, regular counting corresponds to the tempo of regular normal breathing.

c) (Fig. 25a, b, p.385) Another, more commonly applied method of artificial respiration, is the following: The patient lies upon his back; a small roll of clothing or other soft material is placed under the small of the back in order to raise the chest and to facilitate expiration. Inspiration is induced by raising the chest through bringing the arms above and back of the head; expiration is produced by returning the arms downward and in an outward, circular movement to the sides of the body, doubling them at the elbows and pressing the forearms on to the chest (Fig. 25 b). Compression must be followed by relaxation. This alternating compressing and releasing or raising of the chest should also be continued at the rate of fifteen complete movements to the minute for adults and twenty for children, or it may be regulated by counting as in the operation previously described.
The first method (a) is to be favored because it prevents the falling back of the tongue into the throat and because it facilitates the escape of water, mucus or froth from the mouth. This is especially important in cases of drowning when the lungs are more or less filled with water.

**d)** (Fig. 26) The best method for facilitating the escape of water from stomach and lungs is the following: Lay the victim prone upon his face, stand athwart his body, place your hands under his stomach and raise him at short intervals, thus partially doubling the body upon itself. This compresses the internal organs and facilitates the discharge of fluids through the mouth.

**4. Asphyxiation or suffocation** is a condition of unconsciousness and insensibility resulting from suspended respiration. It is caused by a deficiency of oxygen in the system and an excess of carbon dioxide. This may be
produced by strangulation, as in hanging, by smothering or internal obstruction, as in choking, drowning, or by the inhalation of smoke or poisonous gases.

The treatment consists, first in artificial respiration described previously; and, secondly, in restoring the circulation of the blood and nerve currents. This is best accomplished through hydropathic and manipulative treatment described under acute alcoholism. The revival of an asphyxiated person may require long continued effort. Cases are known where by three or four hours of persistent effort, people have been revived after hanging or other forms of strangulation or suffocation.

a) The victims of carbon dioxide asphyxiation die because this gas is heavier than oxygen and therefore does not allow this life-sustaining element to enter into the lungs and tissues of the body. A pulmotor may help to force the oxygen into the lungs and to expel the CO2.

b) While rescuing a person from a room filled with smoke or poisonous gases, a wet handkerchief or other piece of wet cloth should be tied over the mouth and nostrils. Breathing should be restrained as much as possible. Care must be taken not to strike a match as it may explode the hydrogen gas. The windows should be opened or broken at once. This will enable the life-saver to take an occasional breath of fresh air while trying to find and to remove the victim of asphyxiation to the outer air.

5. Bandages. When bandaging wounds, fractures or other bodily injuries, care must be taken not to apply the bandage too tightly. This might seriously interfere with the circulation, especially if swelling develops in the injured parts.

a) Triangular Bandage. One of the most useful bandages in accidents is the triangular bandage. This may be prepared from any square piece of cloth by folding it diagonally in the shape of a triangle. Figures 27, 28 illustrate the application of the triangular bandage to a broken forearm Figure 29 illustrates other uses of this bandage. Fold a square piece of
muslin or other material into triangular form and place against the body underneath the injured arm. Point A is drawn over the uninjured shoulder; point B is brought up over the injured arm and shoulder and knotted or tied to point A behind the neck.

The projecting flap D is folded over the elbow and fastened with a safety pin. This supports the arm in a comfortable position.

The inner surface of the hand must be turned inward and the thumb upward. Fig. 29 shows the application of the triangular bandage to injured hands and feet.

b) Figure Eight Bandage. Fig. 30 illustrates the Figure Eight bandage applied to hand and foot. A long bandage, three or four inches wide is applied with its center to the injured part. The ends are then drawn crosswise around the wrist or ankle and knotted or pinned with safety pins.

c) Roller Bandage Figures 31, 32 illustrate the application of the roller bandage. This bandage may be from a few feet to a few yards in length and of any width best suited for its purpose. The bandage is first rolled up either in a single roll or in two rolls from each end (Figs. 31, 32). The single roll bandage is rolled up from one end and applied by unrolling from one end. It should be applied by winding smoothly and evenly around the injured part, but this is possible only when the part is of even thickness. If the injured part is of uneven thickness, as in the case of an arm from the wrist upward or a leg from the ankle upward, the bandage in order to be applied smoothly and firmly must be reversed upon itself. This is done by placing the thumb upon the bandage where it is to be folded back upon itself, as illustrated in Fig. 31.
d) **Double Roll Bandage.** The double roll bandage is applied with its center over the injured part; both ends cross in the back and are then wrapped around the part in opposite directions. (Fig. 32, no 5c))

e) **The T Bandage** has been described under Sec. XV, No.18.

f) **Head Bandage.** Bandages suitable for injuries to the head or for holding in place compresses to the head are applied as shown in Fig. 33. One bandage is drawn over the head to point c and fastened under the chin at a. The other bandage, no 2, is drawn over the back of the head and the base of the skull, and fastened over the forehead.

g) **When the chin or lower jaw is injured**, bandage (a), which supports the chin, is knotted on the top of the head. Bandage (b) is applied over the chin and knotted at the back of the neck. (See Fig. 34.)

6. **Bites** by snakes, dogs, cats or by persons in an enraged or maniacal condition, should be sucked out immediately if they can be reached, by either the victim himself or by a friend. The mouth of the one who performs this operation must not contain wounds or abrasions and should be thoroughly cleansed with water after each withdrawal of blood. The wound, if necessary, should be widened by an incision and
cleansed with dilute lemon juice. Immediately after this there should be applied a wet bandage or wet pack.

The elimination of any possible infection must be promoted through fasting or raw food diet, manipulative treatment and all other natural methods described in this volume. Of special importance in this respect is the bed sweat bath followed by cold ablutions.

In cases of snake bites, never administer whiskey or other alcoholic liquors, nor stimulating drugs. This is not only absolutely useless but decidedly harmful and dangerous. According to reliable statistics, less than eight per cent of people bitten by rattlesnakes or other poisonous reptiles die from the effects of the venom even though no whiskey is administered. On the other hand, many cases undoubtedly end fatally on account of the whiskey treatment. Excessive stimulation is always followed by corresponding depression and frequently by complete collapse. This is most likely to occur when large quantities of the fiery liquor are poured into people who are not accustomed to its effects.

7. Bruises, Bumps and Contusions. These are treated best by the application of wet packs or clay packs. See Sections XV and XVI.

While bruises and bumps do not bleed externally, the torn blood vessels may bleed internally and cause red or black discolorations. Such internal hemorrhage can be best arrested by firm pressure applied around the affected area; that is, by pressing some hollow object such as a spoon or a cup firmly around the bruise. The cooling packs or compresses will allay any tendency to inflammation or suppuration. Raw beefsteak applied to bruises acts in a manner similar to wet packs.

8. Burns and Scalds. When the clothing is afire one should not run about excitedly, as this will only fan the flames to greater intensity. The best way to extinguish the fire is to throw oneself prone upon the ground and smother the flames by rolling. Rugs, blankets, pieces of clothing or any other material within reach may be used by the victim of the accident or by those who are trying to aid him, to smother and to extinguish the flames. Rolling on the floor prevents also the inhalation of the flames or smoke and the burning of face and hair.

While removing the clothing from a body injured by burns or severe scalds, do not try to tear it off by force, but cut around the places where the clothing adheres to the flesh.

The best treatment for burns and scalds consists in applying a mixture made of ordinary baking soda (bicarbonate of soda) and ordinary boiled oil (linseed oil) or olive oil. This simple remedy which can be procured in almost any household, is of wonderful efficacy in the healing of burns and scalds. It allays pain even in severe and extensive sores and prevents the formation of blisters while greatly facilitating the healing
process. The alkaline sodium neutralizes the poisonous acids which form in the sores and the oil keeps the flesh in a softened condition and prevents caking and cracking.

In cases of very extensive burns or scalds, immersion under water of body temperature or slightly below, has been found very beneficial. In such cases the patient may remain suspended under water in a hammock for days or weeks at a time until the sores are healed sufficiently to allow exposure to the air.

Burning of the eyes and face by strong acids, fresh slaked lime, etc., is best treated by the immediate application of the olive oil and baking soda mixture.

For the treatment of shock due to scalds or burns, see 'Shock'.

Carrying an unconscious person (see Transporting an Injured Person, p.417).

9. Choking. Infants and children frequently choke as the result of swallowing small playthings or other foreign objects. Adults may choke from getting fish bones stuck in their throats or trying to swallow large pieces of meat.

If the patient is a child, place him face downward over your lap, and slap him vigorously between the shoulders. If this does not remove the obstruction, then compress the nostrils, which forces him to open the mouth and throat widely, introduce the fingers of the other hand quickly into the throat and try to grasp the obstructing object. If this is not possible, tickle the palate with a feather, a finger, or with a handkerchief rolled to a point. The tickling will cause coughing or hawking which may dislodge the obstruction.

An adult may throw himself over a chair or table, the head hanging downward, while another slaps him vigorously between the shoulders or, if necessary, performs the operations described in the previous paragraph.

10. Convulsions. These are due either to congestion of the blood in the brain, to abnormal pressure of gas on the heart, or to excessive irritation of the brain or nervous system by toxic substances.

The treatment must be adapted to the individual condition. Most of these have been described in Vol. V under Epilepsy, Uremia poisoning and other forms of diseases.

a) For first aid the patient should be placed in a recumbent position with the head slightly raised. Alternating hot and cold fomentations are most effective for drawing the blood or irritating toxins from the affected area into the surface. The patient should sip hot water mixed with a little lemon juice. An enema of normal salt solution and of blood temperature should be administered as soon as possible. Wet packs applied
to the neck, trunk or extremities will also draw the blood into the surface and thus relieve inner congestion and promote elimination of toxic substances. A full hot bath of body temperature of from ten to fifteen minutes duration may give quick results in serious attacks. This should be followed by a brisk cold saltwater rub.

In convulsions of infants the body first becomes cold and rigid, then the skin breaks into a clammy perspiration, the pulse is weak and rapid. This is followed by convulsive movements and later by a semi-comatose condition which usually passes into a natural sleep.

After the first aid measures herein described have given temporary relief the underlying causes must be overcome by natural methods of treatment.

b) Uremia convulsions frequently occur in the course of Bright's disease and of diseases which cause prolonged retention of the urine in the bladder. In such cases it is imperative to increase the activity of the skin in order to compensate for lessened elimination through kidneys and bladder. The best way to accomplish this is to apply the bed sweat bath described under Sec. XIV, No. 5, p.143.

Sufficient hot water bags, bottles, or heated bricks must be placed outside of the whole body pack and under the outer blanket covering so as to produce free perspiration. The patient remains in the pack from fifteen to thirty minutes, as long as he can endure it.

After the removal of the pack he is quickly rubbed down with cold water, either in a bathtub, spray room or in bed. He is then covered well with blankets in order to induce free "after perspiration". This procedure is repeated as often as the patient can endure it and react to it properly. After the pack has been applied, the patient should drink freely of hot lemonade made with brown sugar or honey. This will promote free perspiration.

Expert massage and neurotherapy treatment should be given to stimulate the circulation, to promote the elimination of morbid matter and to correct spinal or other mechanical lesions. Juniper berry tea (Sec. XIX, No. 5) will stimulate the activity of the kidneys. Fasting is imperative. It must be extended for days or weeks, according to the nature of the disease back of the convulsions. In cases of serious ailments such as Bright's disease, inflammation of the bladder, subacute and chronic prostatitis, the fasting must be followed by raw food diet for weeks or months at a time.

Hot, normal salt enemas should be given to cleanse the lower intestines and to stimulate the vital activities.

For treatment of Epileptic convulsions see No. 14, p.398, this Section.
11. Cuts and Wounds. Small cuts or wounds should be thoroughly cleansed with warm or cold water and then treated with dilute lemon juice. Air and light are the best of all healers. It is injurious to close cuts with adhesive plaster, because it prevents elimination and shuts off air and light. However, in case of large wounds, the edges may be held together with narrow strips of adhesive tape just sufficient to keep the lips together for healing and to allow drainage. When the bleeding has stopped, the wound should be left uncovered if this can be done without exposing it to the pollution of impurities; or, the covering should consist of just enough porous gauze to protect it.

If the wound should prove painful or become inflamed, frequent bathing in cold water or allowing a stream of cold water to run over it, is the best remedy. If the wound is large enough to cause serious or dangerous hemorrhage, appropriate treatment must be applied. For this see "Hemorrhages", No. 18 (a), page 402.

Delirium Tremens. (See Alcoholism, p.379.)

12. Disease, Sudden Onset of. The simplicity of the natural treatment enables us to apply the most efficient treatment at the sudden onset of any disease whatever. While the medical man has to wait for days and sometimes for weeks before he can find out what the exact nature of the trouble is and apply his specific remedy, the natural therapist gives the most effective treatment from the first manifestation of symptoms. In that way he may be able to abort or to avert many serious diseases which might end fatally if neglected for a few days.

At the first appearance of great weakness, of aches and pains in any part of the body, of increased temperature and quickening pulse rate, a normal salt enema (Sec. XVIII, No. 4, p.165,) of body temperature should be administered in order to thoroughly cleanse the lower intestine. This should be followed by a full sheet pack (Sec. XV. No. 7) or by a trunk pack or, if reaction is unsatisfactory, by a full sheet bed sweat bath (Sec. XIV, No. 5, p.143). (See also description in Uremic Poisoning, No. 10. (b) 4 p. 394.)

Fasting must be enforced from the appearance of the first symptoms of malaise or acute inflammatory activity.

If there are signs of poisoning or of severe inflammation of, the stomach and intestines, vomiting should be induced immediately by means of drinking copious quantities of lukewarm water, either pure or mixed with salt or mustard. If vomiting cannot be induced in this way, tickle the throat with a feather or piece of cloth drawn over a sliver of wood. After thus thoroughly cleansing the stomach, allow the patient to drink freely of water mixed with the juice of acid fruits.

Neurotherapy treatment should be given at once to promote heat radiation, elimination of morbid matter, and to correct mechanical lesions.
A few days of such natural treatment will suffice in most cases to restore the system to normal condition. If an acute disease should develop, it will run a much milder end safer course after prompt natural treatment, and the results obtained will be infinitely better than under the old time drug treatment.

Carefully observe the following warnings, though you may find contradictory advice in books on naturopathic and physical and natural culture treatment: **In acute conditions never apply hot water applications nor the ice pack; neither give cold water enemas.** They are very dangerous, as they may suppress the inflammatory process and bring about fatal collapse. In cases of serious shock or collapse where the vitality is too low to react to cold applications, alternating hot and cold fomentations are in order, and the wet packs may be wrung out of hot water instead of cold water.

If the hands and feet remain cold and bloodless the best remedy for bringing the blood to the extremities is good magnetic massage. After the manipulative treatment, firmly hold the hands of the patient or grasp the feet around the ankles and will the blood to flow into the extremities. The magnetic treatment must be continued until the hands or feet warm up.

The hot bath or hot water bag treatment produces warmth temporarily but is followed, in accordance with the law of action and reaction by cold reaction; therefore the anemic condition of the extremities is only made worse by such hot applications.

**Drowning** (See No. 3, pg 383)

13. **Ears, Foreign bodies in**, locate the foreign body by using an ear speculum and head mirror. Turn the patient on the affected side and use a syringe from below, to straighten the canal, pull the outer ear up and back. In some cases forceps made of fine wire may be necessary. Living insects in the outer canal may he killed by the injection of alcohol or oil and then removed by syringing or by the wire loop. In cases of peas or beans, do not use water; it will make them swell. Use a wire loop or attach a strip of adhesive plaster to the foreign body and pull it out that way.

Foreign bodies in the nose may be removed in a similar manner.

14. **Epileptic Convulsions.** Nothing must be done to check or suppress the convulsion; this would be very injurious. All that can be done during an attack is to place the patient in a comfortable position and to elevate the head slightly. A neurotherapist should give firm inhibitory treatment over the upper cervical vertebrae and at the base of the skull. Immediately apply rectal dilatation.

If the fit occurs in the house, the patient should be exposed to a draft of fresh air. Push the lower jaw forward so that the
lower row of teeth projects over the upper. This will keep the windpipe open and prevent choking and suffocation. Push a piece of wood padded with a cloth, a cork or a rolled handkerchief between the teeth in order to prevent biting of the tongue. The opening of the clinched hands is useless.

After the attack the patient should rest until its effects have worn off. The treatment for the cure of the disease must be administered between the attacks. Two-thirds of such cases that have come under our treatment made permanent recoveries.

**Exhaustion.** (See Heat Exhaustion, p.401.)

**15. Eye Injuries.** *(a)* Black eye. Caused by external injury, blows, etc. Natural treatment: Cold applications applied immediately will prevent discoloration and will alleviate inflammation.

Burns. See treatment for burns, No. 8, p.391.

**(b)** Foreign bodies in the eyes, such as cinders, bits of sand, etc. These are usually found imbedded in the cornea or in the lid. Pull the lid outward and bend it backward over a toothpick, a match or other bit of wood, thus exposing the inner surface. Then remove the obstacle with a bit of cotton if it is imbedded in the lid; or if necessary with a toothpick or sharp instrument if it is located in the cornea. Treat inflammation with cold compresses and cold eye baths.

**(c)** Perforating Wounds. Perforating wounds of the eyes should be treated with cold compresses and cold eye bath. The patient must remain absolutely quiet and not expose the eyes to any strain whatever. If the sight is lost and symptoms of sympathetic inflammation appear in either eye, removal of the affected eye may become necessary, but this will seldom be the case if the cold compresses and the potato compress and cold ablutions are applied faithfully from the start (Sec. XV, Nos. 1, 4, pp. 147, 148). In any case of injury do not use vaseline, atropine or antiseptics.

**16. Fainting—Insensibility.** Find out first whether the unconscious one is alive and breathing. Hold a mirror, piece of glass, bright piece of metal or a feather before the mouth and nose. If the patient is still breathing, the bright surface will be dimmed by the breath, or the feather will move.

**(a)** The following is another test for determining whether life is extinct. Raise the eyelid and touch the white of the eye. If life is not extinct, the eyelid will twitch. Observe the odor of the breath. It will indicate such poisons as alcohol, chloroform, ether, etc. If the tongue has been bitten it indicates epilepsy. If the eyes are sensitive to touch and light, there is no brain injury. Unequal contraction of the pupils indicates brain trouble. Pupils contracted to pin points indicate opium poisoning. Slow, weak breathing indicates collapse or shock. Snoring or stertorous breathing and slow, weak pulse
indicates brain trouble. Rapid pulse points to sunstroke. A hot skin and rapid pulse indicate sunstroke or high fever. Cold skin and weak pulse may be the result of fainting, freezing, or of acute alcoholism. High fever should be treated as described under treatment of acute diseases (Sec. VII {pg. 76, 77).

b) If the patient is still breathing, place him in a comfortable position, the head somewhat lower than the rest of the body. Open or cut the clothing wherever it constricts the body, and expose the patient to a draft of fresh air, if in the open, fan the air, over his face.

c) In order to stimulate heart action, apply, alternate hot and cold compresses to the chest; sprinkle or dash cold water over the face and neck; also apply alternate hot and cold fomentations to the, spine. Massage and apply passive movements to the extremities. If the, breathing is very slow and faint, apply artificial respiration (No 3. page 383). Dash cold water on the neck and on the soles of the feet. Give cold salt water rubs, all over the body. Administer a, warm normal salt enema (Sec. XVIII, No. 4, p.165). Do not try to administer water or stimulants while the patient is unconscious; it would only choke him.

d) When he revives do not give alcoholic liquors or other poisonous stimulants. The reaction might prove fatal. Give sips of fresh water mixed with acid fruit juices, or, black coffee or tea in small quantities; repeat until full consciousness has been restored.

e) Try to find out what caused the unconscious condition. It may be the result of any one of the following causes: Fainting; collapse, shock, asphyxiation by gas; drowning or other means, acute alcoholism, opium, chloroform, ether or other drugs, sunstroke, apoplexy, epilepsy, convulsions, injury to the brain by concussion or fractured skull, or it may be caused by certain diseases of the heart stomach or kidneys. Treat accordingly.

17. Fractures. In case of fracture, a physician or Surgeon, must be secured without delay. In the meantime excessive bleeding may be stopped as described under "Hemorrhages" (p.402). Swelling may be reduced by wet packs and cold ablations.

18. Freezing. Frozen limbs, ears, nose or other fleshy parts, of the, body should be, rubbed vigorously with ice water, or snow. Great care, however, must be taken not to break the frozen parts; they are brittle and may break easily.

If a person has become unconscious through freezing, he must be taken into a cold room and treated with cold rubs by means of ice water or snow, until the circulation in the various parts is restored. As before stated, great Care must be taken not to break the frozen parts.

If breathing and heart action are very low or imperceptible,
artificial breathing, with due precautions, must be at once resorted to. The individual condition must determine the best method to be employed. When normal breathing commences, place the patient in a cold bed and heat the room very gradually.

When the body becomes warm, rub with warm flannels, but the frozen parts must still be treated with cold applications and snow rubs.

Warm the body from within by giving hot lemonade with brown, unrefined sugar or honey. Black coffee with lemon juice will stimulate heart action and circulation.

To drink alcoholic liquor in order to keep warm is extremely dangerous. The benumbing after effects of this and other strong stimulants will induce numbness and sleep when wakefulness is necessary to resist the freezing.

19. Heat Exhaustion is usually the result of injudicious diet in summer, excessive clothing, and of working in close, hot, illy ventilated rooms. The principal symptoms are faintness or syncope; a cold and damp skin and a rapid and feeble pulse. When death results it is due to heart failure; but most cases recover. It is not as often fatal as sunstroke.

a) The patient should be removed to a cool place. Hot lemonade will stimulate the heart action; a brisk, cold rub and wet packs, if necessary reinforced by hot water bottles will restore the activity of the skin. (See Bedsweat Bath, Sec. XIV, No. 5, p.143)

b) Both in sunstroke and heat prostration the head should be frequently laved with cold water. If the body temperature is subnormal and death seems imminent, the legs should be wrapped in woolen blankets saturated with hot water. Care must be taken not to scald the flesh. Around the wet blanket wrap several layers of dry sheeting or a dry blanket in order to retain the heat. The patient should take at intervals small quantities of hot lemonade.

Heat Prostration (See Heat Exhaustion, p.401.)

20. Hemorrhages. (a) Hemorrhages from the mouth. When the blood is of dark color and looks as if it were mixed with coffee grounds or food materials it comes from the stomach and the hemorrhage is caused by cancer. If the blood is mixed with food materials but looks bright red, the hemorrhage is caused by ulcers of the stomach. If the hemorrhage is from the stomach, the patient should be placed in a recumbent position. A trunk pack will draw the blood away from the stomach and relieve congestion. The patient should sip at frequent intervals small quantities of cold water mixed with lemon juice, and should be allowed to rest.

b) Hemorrhage from the Lungs. When the blood is bright red and foamy and free from food materials, it comes from the
lungs and is caused by breakdown of the lung tissues. It is not necessarily directly fatal. Under natural treatment of lung diseases, hemorrhage frequently occurs during the crisis periods and is then a form of elimination. In many cases, recovery from tuberculosis has been preceded by copious hemorrhages. The patient should be kept in bed in order to give the disrupted tissue a chance to heal. The treatment must be directed to the underlying disease.

c) Hemorrhages from Cuts and Wounds. If the blood is bright red and comes in spurts, it is an indication that some important artery has been severed and a ligature should be applied without delay above the wound. If on the trunk of the body, pressure should be made above the wound, between it and the heart. Any solid object, a piece of wood, rock or anything convenient, held in position firmly by a bandage or belt will serve the purpose. (Figs. 35, 36.)

d) If the blood is dark in color and flows smoothly, then some vein has been opened and the ligature should be applied just below the wound. (Fig. 37) Any strap, rope or handkerchief may be used for this purpose, but a rubber hose, if it can be procured, is best suited on account of its elasticity. The ligature may be applied more tightly by inserting a stick, pipe or similar object below the knot and twisting it. (Fig. 35.)

Do not try to remove any clots of blood; they are Nature's provision for stopping the hemorrhage. Hemorrhages from large arteries may be stopped temporarily by compressing the blood vessel with the fingers. In order to do this, one must know where to find the arteries.

e) For an injury on the side of the upper part of the head, the temporal artery, must be Compressed with the thumb. This artery is located about three-quarters of an inch in front of the opening of the ear underneath the temporal bone. (Fig. 38)
If the injury is in the back of the head, the occipital artery must be compressed with the thumb. It is located about an inch from the center of the back of the ear. (Fig. 39) The facial arteries can be compressed by exerting strong pressure at a point one inch in front of the angle of the lower jaw. (Fig. 40.) The arteries pass over the jaw at these points. They should be pressed at the same time on both sides.

The common carotid artery can be reached at a point one and a half inches above the joint between the breastbone and the collar bone. Pressure may be exerted inward and backward. (Fig. 41.)

The subclavian artery can be reached at a point behind the middle of the clavicle or collar bone where the hump of this bone is felt. First lower and draw the shoulder forward, then press downward and backward with the thumbs or with the fingertips of both hands. The pressure must be firm and persistent. (Fig 42.)
The axillary artery can be compressed by first raising the arm, pressing it outward and backward, and then compressing the artery on the inner surface of the upper arm. (Fig. 43.)

The brachial artery passes along the inner border of the biceps muscle. First extend or raise the arm, then press outward and backward. (Fig. 44.)

The radial and ulnar arteries in the wrist may be compressed readily with the fingertips. (Fig. 45.)

The great femoral artery in the upper leg can be reached best in the groin just in front of and a little inside of the femur bone. Compress with the thumbs or by using as many fingers as are needed.

The popliteal artery can be reached by strong pressure in the central part of the ham, applied, while the patient is lying on his stomach, directly downward.

The wounded part should be raised as high as possible.

Cold water is very effective for stopping hemorrhages. If possible it should be allowed to run over the wound in a constant stream. This inhibits the circulation and favors the clotting of the blood. Care must be taken not to run the water directly on the wound as this might prevent the forming of clots. In order to accomplish this it may be well to place a cup or saucer or some other protecting object directly over the wound.
Only boiled or aseptic bandages should be applied to the wound. **Clay or mud must never be applied to open cuts or wounds.** Water mixed with lemon juice applied directly to the wound acts as a natural antiseptic and astringent, thus favoring the clotting.

21. **Hiccough or Hiccup.** This is a spasm of the diaphragm, caused by nervous irritation of some kind. It may be due to digestive disturbances or to irritation caused by systemic or drug poisons. In chronic form we find it frequently associated with mercurial, phosphorus, strychnine and other drug poisoning.

Ordinary hiccough requires little or no special attention. If it persists, one of the best remedies is to continuously sip and swallow water until one or two of the spasms have been missed; anything that will break the regularity of the spasm will stop it. Out of this fact grew the old custom of "frightening the hiccough" by a sudden motion or exclamation.

In its most serious forms, in cases of drug poisoning, we have always succeeded in alleviating and in most instances overcoming the spasms by the natural treatment. Certain neuropathic moves give excellent results.

**Insensibility.** See "Fainting" No. 16, p.399.

22. **Lightning Stroke.** If a stroke of lightning results in shock or collapse, treat as described under "Shock", p.414. If it results in burns, treat as described under "Burns and Scalds" (p.391).

23. **Mania.** A sudden maniacal outbreak, whether the result of an attack of insanity, of acute alcoholism or of great emotional excitation, is best treated by cold applications such as cold sprays, cold sitz bath, hip bath, quick submergence under cold water, or by cold wet packs.

Soothing manipulative and magnetic treatment is very effective.

It is wrong to submerge such patients for hours or days in warm or hot water. Such sedative treatment is as weakening as opiates and hypnotics and will only aggravate the underlying conditions which are always negative in character.

Such patients should have nothing but vitalizing, upbuilding treatment. Sedative drugs and long continued submersion in hot water will only aggravate the negative conditions and make the underlying ailments more chronic and incurable.

24. **Mental Disorders.** At the first appearance of symptoms of mental disorder; the patient should be placed in an institution for natural healing, where surroundings and treatment are favorable for early recovery.
25. Nose. (a) Foreign Bodies in. (See "Ears," p.397.)

b) Nosebleed. Sniff cool water mixed with lemon juice. This has an astringent effect upon the capillaries. Compress the nostrils temporarily, throw the head backward, and avoid vigorous blowing of the nose. Apply cold compresses to the neck at the base of the brain. Repose on a chair or couch, perfectly relaxed, in a sitting position and remain that way until the bleeding ceases. Refrain from any movement of the body. Have someone else catch the running blood in a basin or cloth. This is the best way to facilitate clotting of the blood.

If this is not sufficient to stop the bleeding or if it should grow worse have small plugs of cotton or muslin inserted tightly into the nostrils. However, it must be remembered that the bleeding may be a form of elimination. It often occurs as a form of healing crisis and should, therefore, not be interfered with unless necessary to avoid excessive weakening and collapse.

26. Poisoning. (a) The first thing to be attended to in any case of poisoning, whether or not the exact nature of it be known, is to empty the stomach. This may be accomplished by the swallowing of large quantities of Warm water containing the appropriate antidote, and by tickling the palate with the finger or a feather, thus causing copious vomiting. The washing of the Stomach must be repeated several times. If mouth and throat are not burned, a rubber tube may be pushed down the throat into the stomach. By means of a funnel, warm water is poured through the hose until it overflows. The end of the hose outside is then suddenly, lowered below the level of the stomach and water siphoned out of it. This may be facilitated by having the patient assume a position prone upon the face during the draining of the stomach.

b) In emergency cases, mustard, common salt or powdered alum may be given as emetics in proportion of one teaspoonful of either to a glass of water. A lukewarm solution of soap in water is a simple and efficacious emetic. If no emetics are available, cold water should be taken freely and vomiting induced by tickling the throat.

After washing of the stomach, white of egg, milk, or sugared water should be given freely. They are soothing to the inflamed membranes and give the poisons something to work on. Blood warm enemas of normal salt solution (Sec. XVIII; No. 4. p.165) should be given repeatedly in order to eliminate the poison from the intestines. When the patient is strong enough bed sweat baths followed by cold ablutions will stimulate elimination through the skin.

c) In corrosive sublimate or other forms of mercurial poisoning, retained rectal enemas of milk or white of egg beaten up in warm water will help to neutralize the destructive action of the metallic poison.
In all cases, fasting, with dilute fruit juices, should be enforced until the system has eliminated the poison and the injured membranes of the internal tracts have been repaired. Where the latter have been severely burned, fruit juices may cause burning pain unless they are very much diluted with water. In the mild dilute form, they will antidote the destructive effects of the poisons.

So called antidotes are effective only when administered immediately. The general rule is, against acid Poisons administer water mixed with baking soda or fresh Lime; other good antidotes are white of egg, rich milk or oil. These substances neutralize the acids.

Alkaline poisons must be antidoted with dilute vinegar, milk, white of egg and other albuminous substances which neutralize alkaline poisons as well as acid poisons by diluting them and giving them something to work on besides the tissues of the body.

Narcotic poisons like opium, morphine, belladonna, digitalis, poisonous mushrooms, ptomaines, alcohol strychnine, etc., cause loss of consciousness, stertorous breathing, redness of the face, cramps and delirium. If the victim of poisoning is unconscious, artificial breathing must be resorted to (No. 3, p. 383), and the neck, chest and other parts of the body should be sprinkled with cold water. A brisk, cold saltwater rub is very efficacious in reviving the vital activities. As a stimulant administer small doses of strong black coffee.

Arsenic, phosphorus, Paris green, vitriol, carbolic acid, hydrochloric acid and lye do not as a rule cause unconsciousness, but give rise to violent pains in the oesophagus, stomach and abdomen, followed by choking and vomiting. Some of these poisons burn the lips, mouth, oesophagus and stomach; such burns may be treated with a solution of baking soda or powdered chalk. The treatment otherwise is the same as given for alkaline and acid poisoning.

In cases of poisoning a physician should be called in as soon as possible.

Ptomain poisoning results from eating putrefying or decayed meats, fish, cheese, ice cream or other animal food products. The usual symptoms are collapse, subnormal temperature and pain in the digestive tract. Nature generally tries to remedy the trouble by vomiting and diarrhoea. Both these forms of natural elimination must be encouraged by the swallowing of warm water in large quantities and by warm saltwater enemas. (Sec. XVIII, No. 4, p.165.)

The treatment of ptomain poisoning is very much the same as that of other forms of poisoning. The stomach and intestines must be emptied and cleansed as thoroughly as possible by induced vomiting and by saltwater enemas, as
described in the previous paragraphs. After that, the patient should drink copious quantities of fresh water mixed with acid fruit juices. This is much better than the taking of poisonous antiseptics.

While the temperature is subnormal, the bed sweat bath by means of the trunk pack or full sheet pack will promote elimination through the skin. When the subnormal condition is followed by inflammation and fever, cold packs and ablutions are in order and the treatment in general is the same as that for acute inflammatory conditions described under Sec. VII; p.75.

j) External Poisons. Poisons which affect the human body from the outside include poison ivy, poison oak and poison sumac. Poisoning by insects, snakes and rabid animals has been treated under other headings.

Poison ivy and the other poisonous plants above named owe their toxic qualities to an odourless, transparent oil found on the leaves, bark and twigs, which is insoluble in water. These poisons are powerful irritants. Contact of the skin with these poison plants causes insufferable itching, swelling and vesicular eruptions. In severe cases there may be vomiting, colicy pains, fever and delirium. Parts of the body or the entire cutaneous surface may be covered with eruptions.

The U.S. Department of Agriculture recommends the application of a solution of acetate of lead to be applied to the itching skin. This, however, is a powerful suppressant. While the eruption disappears rapidly under this treatment, it drives the plant poison plus the drug poisons into the system, and wherever these concentrate the morbid soil is prepared for chronic disease.

The poison in its outward symptoms, as well as its internal chronic after effects, resembles very closely the psora or itch taint. Its suppression in the acute stages broadens the scurf rim and frequently produces typical itch spots in the iris.

The best homeopathic antidotes in acute and chronic cases are Rhus tox., psorinum or sulphur. The homeopathic rhustoxicana is a trituration of the ivy poison.

The Natural Treatment. First it must be remembered that the itchy, burning eruptions represent Nature's, effort to eliminate the poisons from the system and that therefore it should not be checked or suppressed by any means whatever. The natural treatment includes, everything that will promote elimination of the poison through the skin and other organs of depuration. If water is immediately accessible, a good, thorough scrubbing of the skin with soap and water, or, if in the open, with sand, tufts of grass, or any other, scrubbing material may be sufficient to remove the poison before it will do any harm; at any rate it will greatly reduce the bad effects.

The preliminary cleansing should be followed as soon as
possible by a whole sheet pack or a bed sweat bath, and cold Ablutions. This may be repeated several times if necessary, or followed by partial packs. Otherwise, the treatment is the same as for acute diseases. (Sec. VIII) Fasting and raw food diet are especially beneficial. The cold packs, compresses and ablutions are the best means for allaying the intolerable itching and burning.

**k) Antidotes for Acute Poisoning**

By **Lead**: magnesia, soda or chalk water.

By **phosphorus**: thick liquid gum; white of egg; flour; bread magnesia and cold water, for the purpose of enveloping and isolating the poison. Do not give milk or liquids containing alcohol or oily matter.

By **caustic acids, such as sulphuric, muriatic, carbolic or nitric acid**: large quantities of soap, salt, chalk, limewater or milk.

By **copper and verdigris**, frequently contracted by foods or drinks prepared in copper vessels or by drinks from soda water fountains when the copper has become exposed through the away of the zinc lining: dilute white of egg; milk; water mixed with honey or sugar.

By **iodin**: starch or flour paste.

By **nitrate of silver**: strong saltwater solution; white of egg.

By **oxalic acid**: chalk or lime water.

By **strychnine**: meat burned to a cinder; decoction of acorn coffee; tan or gall apple.

By **arsenic**: warm milk; sweetened water.

**Scalds.** (See Burns p.391)

**27. Seasickness.** The unpleasant sensations accompanying this disorder are undoubtedly caused by a disturbance of the center of equilibrium in close proximity to the, left ear, which in turn affects the entire nervous organism and especially the nerves supplying the digestive organs; causing intense nausea and vomiting.

So far no effective remedy has been discovered for this peculiar disorder. The following directions have in many instances either prevented or greatly alleviated its Symptoms.

Those who intend to travel on the sea should prepare themselves by a brief fast and light raw food diet. This should be continued on board ship. The heavy, rich, greasy foods served in overabundance on board of seagoing vessels undoubtedly have much to do with bringing on the gastric disturbance. The invigorating effects of a sea voyage might be greatly enhanced by a prolonged fast beginning a day or two
before taking passage and extending for a week or more, according to the vitality and recuperative powers of the individual.

The best remedy, aside from these dietetic measures) and according to my experience the most efficient, is getting into harmony with the motion of the vessel or car. Many times outside patients have come to me saying they could not continue coming for treatment because the benefits were offset by nausea and vomiting caused by the shaking of the cars. I have instructed the sufferers from ear sickness as follows:

Instead of tensing yourself physically and mentally against the violent vibrations caused by the rolling of the vessel or car, relax completely. Do not oppose and fight the motions but let yourself go with them. A good way to do this is to hum a tune in harmony with the oscillating motion of the ship or car.

In many instances the very first trial of my remedy has given relief and after a few attempts no discomfort whatever was experienced. Those who are naturally immune to car or seasickness probably practice this form of relaxation and rhythmic adjustment unconsciously.

It is another proof of the truth and practicability of the maxim of the Master, "Resist not evil". Those who most fear this form of evil and tense themselves against it are most affected by it, While the person who thoroughly enjoys sea travel and to whom the rolling of the vessel is a pleasure naturally relaxes to it, enjoys the sensation, and therefore feels no discomfort.

28. Shock is characterized by collapse and frequently by loss of consciousness. It may result from excessive loss of blood or physical injury, or it may be caused by emotional depression resulting from mental and nervous excitation such as sudden fright, grief, anxiety or anger. In many instances it is the shock rather than the actual physical injury which causes death.

If the collapse is due to haemorrhage, this must be stopped as quickly as possible (see p.402). Cool behaviour and reassuring suggestions are necessary to dispel fear and anxiety. The same tonic treatment must be administered as described under fainting, unconsciousness, etc., p.399.

Signs of Life. (See "Fainting", p.399.)

Snake Bites. (See "Bites", etc., p. 390.)

29. Sprains, Strains and Dislocations. Sprains and dislocations of joints must be attended to as quickly as possible by a competent physician, preferably a neurotherapist, osteopath or chiropractor. If, however, a physician is not immediately available and the injury results
in swelling, then cold packs must be applied to reduce the inflammation and to facilitate the adjustment.

If swelling, or pain, make it impossible to remove parts of the clothing or the shoes and stockings, these should be cut away with a sharp knife. The affected part must have absolute rest before and after the adjustment. Do not apply hot applications of any kind.

**30. Sunburns**, which are frequently the result of imprudent exposure in the sun-baths, are best treated by cold compresses and cold ablutions or by the olive oil and soda mixture.

**31. Sunstroke.** Sunstroke is caused by exposure to the direct rays of the sun in a heated atmosphere. Loss of consciousness is caused by the direct action of the sun's rays upon the brain and the cardiac and respiratory centers in the medulla.

a) The onset is sudden. The most prominent symptoms are unconsciousness, pallor, feeble pulse and rapid failure of the heart and respiration. Death is common, recovery often only partial, leaving the brain permanently injured.

b) Under the natural treatment few cases end fatally. The patient should be quickly undressed and cold water poured all over his body, also over the head. This should be followed by brisk salt water rubs; or the body should be wrapped in a wet sheet which must be kept wet by pouring cold water over it from time to time.

If collapse has taken place and vitality is greatly depressed, the patient must be put to bed and well covered with blankets so as to produce a warm reaction.

**32. Thermic Fever** may arise by night or by day through exposure to artificial or solar heat.

Premonitory symptoms are malaise, nausea, diarrhea, giddiness, sleeplessness, after which the temperature rises quickly to 108 to 110 deg F. or even higher. Prominent symptoms are lividity of the face, dispnoea and delirium. These are often followed by coma and death within a few hours. It recovery takes place it is slow and incomplete.

Cold, wet packs, followed by cold ablutions, must be applied. The drinking water should be cool and mixed with acid fruit juices. (See the usual treatment for acute diseases, Sec. VIII.) Under natural treatment few cases end fatally.

**Toothache.** See Section XLIII, No.8, p.430.

**33. Transporting an Injured Person.** To lift or carry an injured person in the wrong way may cause permanent injury or even death; therefore, carefully examine the victim of an accident in order to ascertain whether he has sustained a fracture or serious internal injury.
First aid should be administered at once and on the spot; but if removal is necessary, a stretcher may be improvised out of a board, a door, bedspring, or anything else convenient for the purpose (Fig. 49, p.418). Care must be exercised not to drop the injured one. If a patient must be transported by carrying, the following methods will be found practical:

a) If the injured one can walk, let him put his sound arm around your neck and with one hand grasp his hand hanging down from your shoulder and with your other arm firmly support his body. (Fig. 46).

If the patient is unconscious, the following methods will be found most convenient:

b) You may carry the patient in an upright position, placing your right shoulder under his armpit and your right arm around his waist, his left arm back of your own neck and over your shoulder, taking hold of his left wrist with your left hand. In this way you can either help him walk, as previously described, or carry him entirely. (Fig. 46)

c) If an adult person is unconscious and requires immediate removal, it would be impossible for one person to carry him in his arms. In such an emergency, the pick-a-back method is the most practical. Stoop down and place the patient well up on your back; then pass your right arm around his right knee and with the other hand grasp firmly the wrist of his right hand drawn over your left shoulder. In this way he is in a safe position to be carried for a considerable distance and the weight is fairly distributed and balanced over your back and shoulders.
d) The third method of carrying an unconscious person is similar to (c), the only difference being that your right hand after passing around the upper part of the right leg of the patient, grasps his right wrist, drawing his right arm over your left shoulder and firmly across your chest, as illustrated in Fig. 47 above. This position leaves your left arm free for other employment, if desired.

e) If two persons are available for transportation they may support the injured one on their locked hands, while he places his arms about the necks of his carriers. (Fig. 48)

f) Fig. 49, illustrates an improvised stretcher. Two poles have been slipped through the sleeves and body of two buttoned coats. Other improvisations may be made by means of a board, door, shutter, mattress, etc.

SECTION XLIII

CARE OF THE TEETH

1. Disease of the teeth generally speaking, is the result of two causes: First, malnutrition, which causes deterioration and
destruction of the teeth from within; second, corrosion, caused by systemic acids and other corroding substances which attack, from without, the enamel of the crown and the hard covering of the neck and roots.

Dentists and books on hygiene deal almost exclusively with the last named factor. They have a great deal to say about the regular and thorough cleansing of the teeth, and of dental treatment, but seldom mention the influence of food materials, nutrition and constitutional disease on the condition of the teeth.

That this is not as it should be is proved by the fact that animals living on natural food, as well as savage races, and people who live in primitive surroundings and subsist largely on products of the soil not demineralized and devitalized by modern manufacturing processes, have splendid teeth and retain them to the end of life without tooth brush, dentifrice or the attention of a dentist.

The teeth of animals and humans who live on natural food well adapted to their needs, gradually wear off to the gums with advancing age but do not decay or fall out; neither are they troubled with abscesses, pyorrhea or other diseases produced by unnatural and artificial ways of living.

Regular examinations of children in our public schools disclose the fact that in spite of tooth hygiene taught in the schools and enforced in the homes, eighty-five percent or more are suffering from defective teeth. Of 1694 children examined in six clinics during the year 1913 by Dr. A. F. Foot, only eleven were found to possess normal teeth. Dr. Foot reported to the Second District Dental Society of New York as follows.

"The six-year molars of nearly every child were broken down wholly or in part. In many instances the molars were decayed to the gums. So extensive and far advanced were the defects that corrective treatment, even if it were applied, would have been of little value."

2. This almost universal decay of the teeth is caused:

1. by wrong food combinations;
2. by devitalized and demineralized food;
3. by the action of corrosive substances from within and without;
4. by the softness of the food materials and by their excessive heat and coldness;
5. by hereditary and congenital influences.

Examining these pathogenic factors separately we find that the ordinary diet customary in the home, hotel, restaurant and boarding house, consisting almost entirely of cooked foods, is excessively rich in starches, sugars, fats and proteins, but very deficient in the mineral salts. This is true of these foods even in their natural condition, as they come from the soil; but the
discrepancy between negative food elements and positive mineral elements is much greater after the cereals rice, sugarcane sap and beet sap have passed through the modern milling and refining processes. These leave the white flour, polished rice, decorticated corn products, pearled barley, corn starch, white sugar and corn syrup in a devitalized and demineralized condition. Together with the all-important mineral elements, the foods have been robbed also of their vitamins or life elements. What little is left of the vitamins is destroyed and dissipated by boiling, roasting, frying or fermenting.

Unnatural food combinations, which predominate in acid and pathogen producing negative food substances and are very deficient in the acid neutralizing and eliminating mineral elements or alkaline bases, produce excessive amounts of acids, ptomains, leukomains, xanthins and other pathogenic substances which corrode and tear down the outer enamel covering and internal dentine structure of the teeth.

The destructive effect of acids upon bone tissue can readily be demonstrated by submerging a piece of bone in hydrochloric acid. Within a few days the lime salts constituting the solid framework will be dissolved and abstracted, nothing being left but a soft cartilaginous and gelatinous mass. Submerge an eggshell in strong vinegar; within a few days it will be completely dissolved. In similar manner, acids in the blood and mouth fluids, and acids which form in decaying matter clinging to the teeth and in the hollow spaces between them, will gradually destroy the enamel and dentine.

Refined sugars act very much as do acids. Having been robbed in the refinery of their positive mineral elements, the remaining negative elements, hydrogen, carbon and oxygen, by chemical affinity leech the minerals from the bones and tissues, thus causing gradual decay.

The sturdy Scots owe their tall and large boned bodies to the highly mineralized cereal, fruit and vegetable products of their mountain valleys, the soil of which is enriched every season by the mineral wash from the rocky hillsides.

As long as they lived on whole meal barley bread and oatmeal porridge made from homegrown and home milled cereals, they had splendid teeth. During the last few generations, however, since they commenced to abandon their primitive foods for white bread, white sugar and devitalized breakfast foods, dentists have become more numerous among them.

3. Gingivitis and Pyorrhea. These ailments are so injurious, not only to the teeth, but also to the general health of the body, and they are increasing in frequency with such alarming rapidity that they deserve special attention.

Allopathic medical science declares that gingivitis and
pyorrhea, like all other inflammatory diseases, are caused by germs, and has vainly tried to cure these common ailments by the application of antiseptics and germ killers. We find that as usual the germs are secondary effects, that we must look for the true causes in other directions. These are:

1) Lack of exercise for the teeth and the connective tissues which hold them in place.

2) Inflammation of the gums, caused by hyperacidity of the system and other pathogenic conditions.

3) The corroding action of mineral deposits on the teeth.

Dr. Robert Aiston, a prominent Chicago dentist, who for twenty years has made pyorrhea a special study, says he is positive that lack of exercise for the teeth and the connective tissues which hold them in place, is the principal cause of pyorrhea.

In an interview I had with him lately on the subject, he said: "No man living has made a more exhaustive study of pyorrhea than I have, and I am convinced that the principal cause is the predominance of soft, mushy, cooked food in the customary diet of our American people."

The reasons with which he backs his opinions are very convincing. I shall condense them in the following paragraphs.

The roots of the teeth are held in place by ligamentous tissues and these remain strong and sound as long as they are subjected to normal strain from the push and pull exerted by vigorous mastication. When this ceases, as a result of the continuous consumption of soft, cooked foods, then the dental ligaments and other connective tissues begin to weaken and decay. Stagnation and putrefaction set up inflammation, this produces inflammatory exudates rich in calcareous salts and these in turn form seruminal calculi on the roots of the teeth, so called because these mineral encrustation's are precipitated from the blood serum. The doctor showed me a number of teeth which were thickly covered with these rough, earthy deposits.

I fully agree with Dr. Aiston that local stagnation, due to lack of exercise, is one of the primary causes of inflammation and destruction of the dental ligaments, but I believe that this is greatly facilitated and aggravated by pathogenic materials and disease taints in the circulation, and in the very beginning by mineral encrustation's on the surface of the teeth.

Elsewhere I have mentioned that in several cases pyorrhea entirely disappeared after the patients had been cured, by natural methods, of smallpox, gonorrhea, syphilis and other acute, eliminative diseases. Healing crises eliminated the disease taints; raw food diet reduced the "calcareous exudates" and scoured the teeth of slimy and earthy...
deposits. In this connection I should mention that after the adoption of a raw food diet mineral deposits on the teeth at first increase. This is caused by the neutralization of large amounts of acids. But as the acidity, under the influence of alkaline diet, diminishes, mineral precipitation ceases, inflammation subsides, the encrustation's on the teeth are gradually absorbed and the gums have a chance to heal.

Pyorrhea, as well as other chronic ailments, can be cured only by restoring the entire organism to a clean, normal condition.

**Gingivitis.** The mineral deposits on the crowns of the teeth, usually light, gray in color, are commonly called tartar. Dentists speak of them as salivary calculi, because they are formed by earthy precipitates from the saliva. These tartar deposits may encroach under the borders of the gums, and this, together with slimy, mucoid accumulations, gives rise to inflammatory, destructive processes in the gum tissues. This is commonly called gingivitis. It is the forerunner of pyorrhea. The only difference between the two ailments is that in pyorrhea the mineral deposits form on the necks and roots of the teeth, and that these seruminal calculi, are blacker, harder and more destructive than the tartar on the crowns. The sharp earthy crystals help to corrode the dental ligaments, aggravate the inflammatory processes, and thus in turn increase the inflammatory exudate of calcareous matter. Filthy, putrefying matter could not accumulate around the teeth and under the gums if the food contained sufficient coarse, scouring material.

Thus it will be seen that the two causes, stagnation due to lack of exercise, and mineral precipitation due to hyperacidity of the system, seesaw in the causation of gingivitis and pyorrhea.

**The Rational Treatment of Gingivitis and Pyorrhea**

It is well enough to scrape from the teeth the earthy encrustation's which cause the gums to recede and to putrefy, but what good does this when the hyperacid condition of the system makes new deposits?

Many people have the idea that they can safely eat meat, eggs and large amounts of starchy foods as long as they consume with them plenty of the mineral salt foods, such as fruits and vegetables. As explained in Vol. I of this series, in Chapter XXIX, this is a mistake. The intake of too much starchy and protein food leads to the excessive production of acids and other pathogenic substances. Though these are neutralized by alkaline mineral elements, more earthy salts are thus formed than can be properly eliminated through the skin and kidneys. These salts collect on the teeth as tartar, or they may form deposits in the joints resulting in rheumatism.

**4. In order to prevent** these and a host of other acid diseases, it is not enough to adopt a vegetarian diet, but the
intake of vegetables, starches and proteids must be kept within normal limits. How to accomplish this I have explained under the heading of food combinations in Section 1, No. 10, pp. 23, 24.

Normal consistency of the food also has much to do with the preservation of the teeth. The perfect condition of the teeth of wild animals and of primitive man is partly due to the fact that they consume their foods in the natural raw condition, thus giving the teeth plenty of wholesome exercise by the gnawing, grinding and crunching of bones, grasses, raw cereals, fruits and nuts. While savage or primitive people cook some of their food, they use much more raw food than do their civilized cousins.

Cooked food, in which most of the vitamins have been destroyed, is much more prone to acid formation than live, raw food. Physicians and dentists frequently warn against acid and sub acid fruits "because they destroy the enamel of the teeth." This is a mistake. The live organic acids of fruits and vegetables, charged with vitamins, have not a destructive effect upon the bony structures as do the disease producing acids formed by abnormal food combinations and putrefactive processes. The malic and citric acids of the fruits are highly organized and help to dissolve the earthy deposits in the joints, and the tartar on the teeth. (See footnote page 434.)

**Unless the diet contains liberal proportions of raw vegetables, fruits, roots and nuts, which are splendid natural scourers and cleansers, the teeth are bound to deteriorate and decay.**

Even the teeth of cows become loose and fall out when the animals are fed continually on the soft, sloppy, devitalized and demineralized cereal offal of breweries and distilleries.

To begin the day and to end it with the munching of an apple or some other raw fruit or vegetable relish, is the best way to keep the teeth in a perfectly clean and sound condition.

Another reason why dentistry in civilized countries is one of the best paying professions, is the habit of swallowing food and drink, either very hot or extremely cold. Not infrequently the piping hot soups and other viands are washed down with ice water or immediately followed by ice cream, sherbet or other chilled desserts.

The sudden expansion and contraction due to contact with excessive heat or cold causes the enamel to crack and thus exposes the dentine of the teeth to the destructive activity of acids and other corroding substances.

When prospective parents have destroyed their teeth by unnatural practices, how can they expect to produce offspring with sound bones and teeth? When the blood of the mother is utterly deficient in the bone building mineral elements, is it any wonder that the new born comes into the world
handicapped for life with a dwarfed, defective bony framework? The formation of tooth substance begins in the embryo after the sixth week and continues all through gestation. This further reveals how important it is that the food of the mother contain sufficient amounts of the bone and teeth making elements. This is possible only when her diet includes an abundant supply of fruits and vegetables, hulls of grains and other mineral salt foods; classified under Group V of the food Table, page 33.

I have observed in many instances that when the prenatal structure and chemical composition of the teeth is abnormal, natural feeding after birth cannot always make good for the defective foundation. An imperfect, cankered Seed will not produce a perfect tree, even though the soil it grows in contains abundant nourishment.

5. Cleaning the Teeth. By the foregoing I do not wish to depreciate the importance of keeping the teeth in a clean and sweet condition by careful scrubbing several times a day, particularly in the morning and before retiring. If convenient it should be done after every meal.

However, we do not favor for this purpose the use of preparations containing poisonous antiseptics. These are readily absorbed by the tender tissues of the mouth and in time will cause trouble in the body. Practically all tooth powders, pastes and lotions sold in the drug stores contain such deleterious substances. These are not only decidedly harmful, but entirely superfluous because the best tooth wash is fresh, cool water made slightly acid with lemon juice. Brisk scrubblings of the teeth with this natural dentifrice will keep the gums and teeth in clean and sweet condition. This should be followed by rinsing the mouth with fresh water. The scrubbing should be done from above downward and from below upwards. This will tend to pull the gums over the teeth and to cleanse the crevices between the teeth from food particles and slimy accumulations.

Another good treatment is to dip the forefinger into cold water and give the gums, inside and outside, a good rubbing and kneading. Always finish by rinsing the mouth thoroughly with water as cool as the gums will endure.

If there is a tendency to the formation of tartar the teeth may be thoroughly scoured a few times a week with ground pumice stone, whiting or oyster shell, but this must not be repeated too often because it might injure the enamel.

It goes without saying that the teeth should be looked after by a competent dentist at least every six months, and that defects of any kind should be attended to promptly. Many a tooth can be saved by a timely filling, a well fitted crown, or good bridge work. These matters must be left to the skill of the dentist. The better he understands his art, the more economical will be his services in the long run.
6. Foci of Infection and their Suppression. The latest theory of medical science is that rheumatism and a number of other acute and chronic diseases are caused by germ infection from suppurating tonsils and adenoids, from abscesses in the teeth and ulceration and pyorrhea of the gums. These shortsighted deductions are the natural outgrowth of the germ theory and of the local and symptomatic conception of disease.

We find in our institutional work that the aches and pains of rheumatism, headaches and asthmatic spasms, etc., come and go, rise and fall in exact proportion to the increase and decrease of acids and other pathogenic materials in the circulation. I do not deny for a moment that the pathogenic materials in these foci of infection may start or aggravate acute conditions in other parts of the organism, but is it sufficient to suppress the foci of infection with antiseptics and surgical treatment? The question is, what causes the foci of infection, the suppurating tonsils and adenoids, the abscesses in the teeth, the ulcerating gums and jawbones?

Does medical science imagine that the suppression of these foci of infection with poisonous antiseptics and surgical operations solves the problem? Why cannot they see that this also is rank suppression and not cure? Can a healthy body, endowed with pure blood, normal tissues and perfect mechanical structural alignment, develop such foci of infection? What is the use of suppressing these symptoms of constitutional disease in one place and having them bob up at another place in more destructive form? Of such nature are the great achievements of modern medical science.

7. This latest craze has led in innumerable instances to the pulling out of whole sets of teeth because one or more were abscessed or because of the presence of so-called pyorrhea, which frequently is nothing but a raw condition of the gums induced by encrustation's of tartar on the roots of the teeth. I meet almost daily with people who have been robbed of sound teeth, sometimes of entire sets, on the assumption that it would cure their rheumatism or other constitutional diseases. To their sorrow they find that the cruel sacrifice has brought no relief so far as their chronic ailments are concerned.

Such criminal experimentation is on a level with tearing out sound ovaries with the idea of curing epilepsy or other chronic diseases. I have known of a number of such uncalled for mutilations. In no instance has the unnatural treatment benefited the patient; it has only served to aggravate the chronic ailment and to hasten physical, nervous and mental breakdown.

The constant suppression of symptoms of disease by drug poisoning and surgical mutilations creates chronic invalidism, hereditary disease, and defectives. Is it not more rational to put the system, through natural living and treatment, in such a pure and wholesome condition that it cannot develop inflammation and suppuration of the tonsils, teeth, gums and
jawbones? Such is the practice of the new school of healing.

8. Toothache. One of the most excruciating tortures that man inflicts upon himself by wrong living, is the toothache. All the causes I have enumerated and described help to create it, and avoidance of these causes is the best prevention.

There are two general types of toothache, the acute inflammatory, accompanied by heat and swelling, and the cold neuritic or neuralgic.

a) The acute inflammatory may be due to congestion and irritation of the blood vessels and nerves of a tooth or row of teeth by systemic poisons, in the same manner that inflammations arise in other parts of the system as the result of pathogenic obstruction and irritation. Acute inflammation may arise when the nerve of a tooth becomes exposed through decay of the bony structure. In that case the attention of a dentist may become necessary. But care must always be taken not to cover decaying particles with a filling or crown. The parts to be covered must be carefully cleansed of all materials that might cause further putrefaction.

b) Treatment. The acute inflammatory toothache is best treated by retaining cool or cold water in the mouth until it warms up, when it should be spit out and replaced. At the same time cooling compresses or packs should be applied to the cheek on the affected side. The pack as usual consists of a piece of muslin, folded from three to six times, and wrung out in cold water. The cold compress is then covered by one or several folds or dry flannel or woolen cloth. The compress or pack may be kept in place by one of the bandages described on page 390.

An acute congestive toothache may be greatly relieved by gentle downward massage movements along the veins and lymphatics in the neck. Thorough drainage of these vessels will do much to relieve the congestion in the affected parts. While giving the massage movements, also use your mental power to combine with the mechanical treatment the magnetic effects. Osteopathic, chiropractic and naprapathic treatments prove very effective in many cases.

In serious attacks the local water treatment may be reinforced by a whole sheet pack, bed sweat bath, or body or leg packs followed by cold ablutions (Sec. XV, p. 147). During the night the sufferer may at intervals take a cold rub and go under the bed covering without drying. All these water applications draw the blood away from the congested area into the surface and thus relieve the local congestion and excruciating pain. They also promote the elimination of the pathogenic materials which are the primary cause of the trouble.

If acute inflammation within and around the teeth were always treated in this way it would seldom come to the formation of acute or chronic abscesses. The pathogenic
materials would be absorbed and eliminated immediately.

Of equal importance with the water treatment is fasting. From the first appearance of a toothache, absolutely no food should be taken until it has ceased entirely, and even then the fasting should be continued for a day or two in order to clear up the constitutional condition which caused the local inflammation. Fasting alone in many instances has cured the severest toothache.

I would **warn strongly against the use of poisonous pain killers.** They only serve to paralyze the nerves and do not in any way remove the underlying causes of the trouble. They add drug poisons to disease poisons and thereby accelerate destruction of the teeth and the gums.

c) **Neuritic Toothache.** This type of toothache is not accompanied by great heat and swelling as is the inflammatory kind. It is usually caused by the exposure of a nerve, or by the irritating effect of some systemic or drug poison. If caused by defects of the teeth and by exposure of a nerve, proper dental attention is of course indicated.

This type of toothache is much more stubborn and does not yield to treatment as easily as does the acute inflammatory kind. Cold water, magnetic and manipulative treatments give but momentary relief. The reason is that the pain will continue or will return at intervals until the poisonous irritant is removed or until the nerve is killed or protected. Sometimes the jaw bones and cheek bones are more affected by these neuritic toothaches than are the teeth themselves. This is usually due to the action of some irritating poison.

d) **Treatment.** In these cold, persistent forms of toothache, hot applications sometimes give better relief than the cold applications, though the relief is temporary.

A remedy worth trying when cold treatment fails, consists in the application of a muslin bag partly filled with hot salt and held in place by a bandage. The salt should be as hot as it can be endured.

The only way these neuritic toothaches can be permanently cured is by eliminating the poisons which are at the root of the trouble.

In many cases we have found mercury, iodine, arsenic, quinine, or other drugs to be the real cause of the disturbance.

Elimination of these hidden enemies can be accomplished only by thorough systemic treatment and natural methods of living.

Many dentists are in the habit of using large doses of iodine, arsenic or other powerful poisons for killing the nerves. They should be warned not to use any more of these destructive poisons than is absolutely necessary. If the work
can be accomplished without using them at all, so much the better.

I would also warn strongly against amalgam fillings. The amalgam or silver filling, so called, contains about 50% of mercury. Acids in the blood and in the fluids of the buccal cavity have a tendency to dissolve the mercury and to create bichlorid of mercury and other mercurial salts which will accumulate in certain parts of the body for which they have a special affinity, particularly in the brain and spinal cord. I am aware that such warnings are pooh-poohed and ridiculed by many dentists, but practical experience tells a different story. The blackening of the teeth indicates formation of mercurial salts. In numerous cases, we have observed pronounced symptoms of mercurial salivation, such as metallic taste in the mouth, ulceration about the necks of the teeth, fetid breath and abnormally increased flow of saliva, which did not disappear until the amalgam fillings were removed from the teeth and replaced by gold, or porcelain. Gold filling, whenever it is practicable, is undoubtedly the best of all.

I know skilled dentists who have discovered these facts for themselves in the course of practice and who have discontinued the use of amalgam fillings on this account.

Of late I have met with several cases of paresis which showed distinctly the sign of mercurialism in the iris. Inquiry revealed the fact that these patients were dentists who for many years had been in the habit of mixing the amalgam and alloy in their bare palms. Mercury had thus been absorbed and was responsible for the destruction of brain substance.

Referring to statements made in section XLIII. 1. In the last paragraph I call attention to the fact that acids act differently on dead and living tissues. The hydrochloric acid secreted by the stomach in normal solution does not affect this organ injuriously, while it readily decomposes the stomach of a dead animal. The same principle holds true in relation to the action of fruit acids on dead and live teeth.

SECTION XLIII

WHY GROW OLD?

"What a question," you exclaim, "We grow old because we cannot prevent it; because Nature has decreed it so."

Of course we shall grow old in years but if we live in harmony with Nature's laws we need not grow old in mind or heart nor lose our physical energy and our alertness and suppleness of body and mind long before the expiration of our allotted time. While growing older in years we should grow younger and more robust as far as our intellectual, emotional, moral and spiritual qualities are concerned.

As regards longevity and the possibility of retaining our
youthful qualities to very old age, we meet with two extremes of opinion. Many mental scientists and new thought people tell us in their lectures and writings that it is not impossible to achieve immortality and perpetual youth in the physical body on this earth plane; that we die long before our time because we imagine we must; that a short-lived existence was necessary for animals and human beings in the early stages of evolutionary development, but that now since the physical body has become more perfect the necessity for dying has passed away and that as soon as we can exterminate the old age and death thought which has become race habit, the "last enemy" will be vanquished and immortality and perpetual youth in the flesh will become the common heritage of human kind.

The majority of mankind entertains an entirely opposite and somewhat pessimistic opinion as regards longevity and the preservation of youth. They are convinced that growing old and decrepit, that losing the enthusiasm, beauty and efficiency of youth is inevitable. They argue that growing old or dying young, health or disease, depend upon heredity, environment, colds, drafts, germs and other accidental circumstances over which we have little or no control. One prominent physician recommended the chloroforming of people over sixty years of age. These two opposing views were brought home to me quite vividly some time ago, while attending a lecture by a well-known mental scientist. His subject on this occasion was "Perpetual youth".

In alluring language, scintillating with plausible argument and beautiful metaphor, he proved to his own satisfaction the possibility of perpetual youth and life everlasting in the physical body. After the audience had given fervent expression to its approval of his lofty idealism, an elderly gentleman in the audience arose and delivered his views on youth and longevity in a pessimistic wail that was taken in shorthand by a stenographer present in the audience.

"This subject of perpetual youth as put forth by our speaker is a beautiful theory. It is a wonderful theory, but I am very clear that it does not work out in life. I do not believe there is such a thing as perpetual youth. It is an ideal belief. You cannot by any process known to human science or human ingenuity turn back the wheels of time or stay them in their revolution."

"This fountain of perpetual youth old men have sighed for, old women have prayed for, and in search for it from time immemorial young women have appropriated their husbands wages and poured their money into the cash box at the drug store; but they have never yet found it."

"It is true that by right thought and right action you can probably postpone old age, but you can postpone it only to a very limited degree. The speaker stated that seventeen hundred people in the United States had reached the age of one hundred years, but he did not tell you how many of them
are paralyzed, how many of them are palsied, how many are
more dead than alive.

"He tells you that with advancing age the arm of the
blacksmith grows stronger. This is true for a certain time, but
its strength reaches its zenith, then it grows weaker and
weaker until it hammers no more. Young man, you cannot
turn back the wheels of time and you cannot stay their
revolutions. The time that is past is laid to rest in eternal sleep;
it is buried in the mysterious realm of oblivion.

"Time robs the bridal wreath of its beauty. Time writes
wrinkles upon the brow of the aged. You may wreath,
garlands and place them around the brow of youth, but the
onward march of time sees them wilt and mingle with the
dust.

"The birds that sing so sweetly will return in the spring.
The flowers will return and bloom again, but, ah, my friends,
youth is gone. It is past forever. It never returns, but age is
real and forever-perpetual youth is no more than a beautiful
dream."

As regards the possibility of life everlasting on this earth
plane, I for my part would gently but firmly decline it. The
idea of living in the same old place forever and forever is not
attractive to my mind. I imagine in time it would become too
monotonous.

To me, life is a great school; a school of personal effort for
the development of our latent god-like faculties, capacities
and powers. This school takes in all there is in the sidereal
universe. Its course in length of time is eternity; its classrooms
and laboratories are the solar systems and their planets.
Whenever we have learnt all there is to learn; all there is to be
acquired of knowledge, wisdom and experience in this great
school of life, then it will be time for us to die. The only death
I know of is stagnation and retrogression. Life is growth;
growth is change, continual, perpetual change—senescence
and rejuvenescence, as science calls it. Death is only a phase
in this continuous process of change.

The majority of mankind look upon death as the greatest
evil in life. They think of it with despair and terror. Some
commit suicide because they are afraid to die—a strange
paradox, inspired by fear, fear of something that is in reality
the greatest of all blessings, the birth into a new and brighter
world with new life, new youth, new and broader possibilities,
after we have acquired all there is to be learned in one brief
earthly pilgrimage.

Why grieve for the loss of loved ones who have made the
great transit before us? Shall we not be glad to meet them
when we arrive on the other shore? If we had to travel on a
long journey to a foreign country, wouldn't we be pleased to
meet with friends among strangers in a strange land?
Life on earth is only the kindergarten in the great school of the universe. Even the greatest and wisest of men that live on this earth are only in the lower grades of the great Cosmic University. Why should we fear to pass on? Nobody would like to remain in the primary grades all his life when there are so many more interesting, useful and beautiful things to be learned in the higher grades.

One New Thought philosopher argues that immortality in the flesh, or at least a prolonged term of life on this earth, is necessary in order to acquire all there is to be learned and experienced in this beautiful world of ours and in order to permit the law of compensation to work out the great chain of cause and effect.

How much more reasonable and beautiful than this idea of continuous existence on earth is the philosophy of Karma and reincarnation of the ancient wisdom religion. Is it not better to have the arduous training of earth life alternate with vacations in the spirit land, and to return oblivious of previous existence's with their depressing burdens of errors, sins and sorrows? Thus death on one plane of life becomes birth into another, and vice versa.

In this continuous change from the old age of one life to youth in another life, lies for me the true solution of rejuvenescence, of immortality and of perpetual youth.

If we look upon life from this higher and brighter viewpoint, how can we grieve at growing old? How can we fear death? Those who are in conscious touch with life on the spiritual planes tell us that beings of high spiritual development appear in a condition of youthful maturity, combining the wisdom of millenniums of spiritual and celestial existence with the beauty of perpetual youth. It is not knowledge, wisdom and experience that causes premature senility and death, but wrong thinking, feeling and doing. Aside from unnatural physical habits of living, nothing promotes senile decrepitude like fear of disease and death, bred through ignorance of life's great laws.

He who looks at life from the higher and brighter viewpoint enjoys advancing life in ever greater serenity of soul and happiness of spirit. He rejoices in ever greater expansion of mind and deeper understanding of life's mysteries. He is justly proud of every year added to a life of usefulness to himself and to his fellow beings. Such a one has only pity for the pessimist's wail previously recited. Such gruesome thinking and feeling is the very essence of black magic that ages and stiffens the body and pencils wrinkles on the brow.

To grow younger as we grow older, we must practice white magic. The body is an electrotype of our mental images. Physical matter convolutes to the mental and psychical or soul pattern. "As a man thinketh in his heart, so is he," or as Gautama Buddha expressed it, "I am today what my past
thoughts and feelings have made me."

See yourself in your mind's eye as always beautiful, vigorous and active, as in the prime of youth, for "A man is never older than he feels, and a woman never older than she looks." "But", you ask, "how shall we keep our looks young?" That is simple. Bathe daily in the sparkling waters of serenity of mind and of cheerfulness and in the milk of human kindness. Learn how to relax completely in body, mind and soul and never entertain discordant and destructive thoughts and emotions.

Physical Causes of Senescence

Mental magic alone, powerful as it may be, is not sufficient to prevent the aging of body and mind. We must also live in harmony with the laws of the physical. No matter how good a watch you have, if you allow it to fill up with dust, dirt and corroding acids, it will soon lose time and finally stop entirely. This is exactly what happens to the human clock when it "grows old'.

As philosophy has two divergent opinions concerning the prolongation of life, so has physical science two theories concerning the causes of senescence or senile deterioration. According to one of these theories, the animal and human being is endowed at birth with a certain amount of vitality, or with a certain momentum of vital force. When this is gradually spent in course of time our powers begin to wane; as a result of lowered vitality the vibratory power to expel waste declines; blood and lymph vessels become obstructed, joints stiffen, brain and nerve matter hardens and we grow old and decrepit.

Certain facts in Nature favor this viewpoint. Even under the most favorable conditions in the freedom of Nature animals live only to a certain age limit. Each species and family of creatures seems to have its own allotted lifetime or age limit. When this limit is reached they suddenly decline and die. I say "suddenly" advisedly. They do not spend a third or a half of their lifetime in getting old and in dying like the average human being. They retain their full vigor and beauty of form almost to the end of life. It is of rare occurrence that a hunter kills an animal that is found to be diseased or deformed. Among antelope, deer and elk the oldest bucks are usually the leaders of the herd. In order to maintain their supremacy they must fight and vanquish their younger rivals.

So human beings when living the natural life, physically, intellectually, morally and socially, will reach the no limit fixed by Nature for the human species in full possession of their faculties, capacities and powers, and will depart from life peacefully. Death will be as painless and sweet as sleep. I believe that in higher reaches of evolutionary development yet to be attained by mankind, the transition from earth life into spiritual life will not mean the passing "through the valley of the shadow" but that human beings will make the transition in
full possession of their waking consciousness.

The opposite theory advanced by physical scientists as regards the causes of senescence, postulates that vital energy is generated by the cells, tissues and organs of the body, and that as these with advancing age deteriorate and disintegrate, vital energy ceases to be generated and the constituent elements of the body become unfit to carry on the vital activities.

Natural Therapeutic philosophy teaches that the physical body is an instrument for the manifestation of the great life force which is divine life, intelligence and creative power. God or Nature evidently does not intend us to live on this earth forever in one continuous stretch of life and therefore has wisely limited the supply of vital force as well as the durability of the physical body in accordance with the laws governing incarnation and reincarnation on the physical and spiritual planes of life.

As before stated, even the healthiest animals living in the most congenial surroundings in the freedom of Nature do not much exceed their allotted span of life, nor do they fall much below it. As a rule, the longer the period between birth and maturity, the longer the life of the animal.

All the different families of mammalia, when living in freedom, live closely up to the life period allotted to them by Nature. Man is the only exception. It is claimed that according to the laws of longevity his average length of life should be considerably over one hundred years, while according to life insurance statistics the average is at present about forty years. This shows an immense discrepancy between the possible and the actual longevity of man.

Even this brief average span of life means for the majority of mankind little else than weakness, physical and mental suffering, premature senility and death. Visiting physicians of the public schools in our large cities report that seventy five per cent of all school children show defective health in some way. Diagnosis from the eye proves that the remaining twenty five per cent are also more or less affected by hereditary and acquired disease conditions. Christian Science says, "There is no disease". Nature's records in the iris of the eye prove there is no perfect health.

These established facts of greatly impaired longevity and universal abnormality of the human race would of themselves indicate that there is something radically wrong somewhere in the life habits of man, and that there is ample reason for the great health reform movement which was started about the middle of the last century by the pioneers of nature cure in Europe and which has since swept, under many forms and guises, all portions of the civilized world.

When people in general grow better acquainted with the laws underlying prenatal and postnatal child culture, natural
living, and the natural treatment of diseases, human beings will approach more closely the normal in health, strength, beauty and longevity.

However, to reach this ideal of perfect physical, mental and moral health, succeeding generations will have to adhere to the natural ways of living and treating their ailments. It cannot be attained by the present generation. Those enthusiasts who claim that they can, by their particular methods, achieve perfect health and live the full term of human life are destined to disappointment. We are so handicapped by the mistakes of the past that the best which most of us adults can do is to "patch up", to attain a reasonable measure of health and to approach somewhat nearer Nature's full allotment of life.

Growing old consists in the accumulation of waste and morbid matter, earthy deposits, destructive acids and alkaloids, causing the stiffening and hardening of joints, bones, veins and arteries and the gradual loss of physical and mental energy.

Do you ever stop to think how this clogging and corroding of the wheels of life is promoted and accelerated by wrong habits of eating and drinking? Food chemistry as taught by the school of Natural Therapeutics clearly shows that excessive use of starchy and proteid foods is the most prolific cause of disease and of premature old age. These classes of foods create in the body a large variety of destructive acids, ptomaines and alkaloids, such as uric acids, sulphuric acid, oxalic acid, indican, xanthins, creatin, etc.

Flesh foods especially favor these morbid accumulations because they are already saturated with all the waste products of the animal carcass. The poisonous xanthins of coffee and tea are almost identical with uric acid. While at first they over stimulate the organism, the second and lasting effect is to benumb and paralyze heart and nerves and to retard elimination, thus causing directly and indirectly retention and accumulation of waste matter in the body.

For these reasons, we of the Natural Therapeutic school realize that the only way to keep the system pure and sweet and its vibratory activities vigorous and harmonious is to reduce in the daily dietary the allowance of starchy and proteid food and to use a larger proportion of fruits and vegetables whose alkaline elements tend to dissolve and eliminate the acid crystallizations and deposits in the tissues.

This becomes more imperative as we grow older. A young and growing body, physically active in play and sport, needs a great deal of sugar and of proteid to furnish fuel and to feed and repair the rapidly growing and changing cells and tissues.

When we pass the meridian of life, growth ceases; there is much less physical activity and therefore much less need of starchy, fatty and albuminous elements. Therefore, as we advance in years these foods should be reduced in amount and
replaced by the dissolving and eliminating fruits and vegetables, but conventional habits and the doctor's advice usually favor the opposite course.

"You are growing older," says the doctor; "you must have plenty of strengthening foods—meats, eggs, fish, fowl—and you need some stimulants. Coffee or tea is all right and an occasional glass of beer or of "Duffy's Old Malt" won't hurt you, either."

Frequently a patient tells us, "All the young people in our house are now living on the natural diet, but you know father and mother are growing old and they must have their soup and meat, their coffee and beer; in order to keep up their strength."

Reverse the prevalent ideas on hygienic living and you are just about right; so in this regard the very opposite policy should be adopted. The older we grow, the less we need of the heavy, clogging foods and the more of the light and purifying.

The majority of people eat too much anyway. Habitual stuffing practiced through many generations has made it second nature. Many consume the best part of their available vital force in endeavoring to digest and eliminate superfluous quantities of food and drink. Every ounce of food in excess of actual need wastes vital force.

A Roman proverb said: "Plenus venter non studet liberenter"—a full stomach does not like to study.

Vital energy required to remove useless ballast cannot be transformed into physical or mental energy. Vital force is a primary force. It cannot be eaten. It comes from the source of all life and is independent of the physical body just as electricity is independent of the bulb which it fills with light. Food can only furnish fuel material for the flame of life and keep the human organism in such condition that vital force can manifest itself in it and through it. If food and drink could give life they should prolong it indefinitely; in that case the glutton and drunkard would live the longest, but common experience teaches us that the man temperate in all things best preserves his physical and mental vigor and lives the longest.

The beauty about all this is that nature cure philosophy does not confine itself to visionary theorizing, but that it "delivers the goods". If we can take all sorts of chronic incurable diseases and within four or five months or a year's time work a wonderful transformation and actually cure the majority of such patients and give them a new lease on life, why should it be impossible to prolong life to its natural limit and to retain to the last, unimpaired, our faculties, capacities and powers of body, mind and soul?

How much greater would be the possibilities for health and longevity if human beings were brought into life and treated in the natural way from the beginning; that is, from the time
of mating and conception through the prenatal and postnatal periods and on through youth and maturity. Within a few generations the offspring of such Natural heredity would live the full allotted time of a hundred and fifty years in perfect health, strength and beauty, thoroughly efficient in the business of life, a true aristocracy not of vitiated, degenerated blue blood, but of pure red blood of perfect buoyant health.

Many of our young people are now beginning to carry out this great plan for the creation of a better, healthier and more beautiful humanity. They are seeking partners among those who have been educated and trained in the ways of natural living. If the offspring of such naturally mated couples do likewise and select their partners in turn from among those who are the product of natural heredity, what a different humanity will inhabit this earth within a few generations.

This is not vain dreaming. It is marvelous how the youth of this country have taken hold of these new ideas; how many are adopting the new life in harmony with Natural Therapeutic philosophy, physical culture teachings and other Systems of natural living and healing. Quite frequently young couples come to me, saying, "Doctor; we want to get married; but before we do, give us a thorough examination and, if necessary, we intend to take a course of treatment in order to put our bodies in right condition for the great responsibilities of matrimony and procreation."

What wisdom—what a glorious promise of a better; healthier and happier humanity!

**How to Grow Younger**

Keep in the light—cultivate the air and light bath—nothing sweet or beautiful grows or ripens in the darkness.

Avoid fear in all its forms of expression; it is responsible for the greater part of human suffering. The only thing to fear is fear.

Don't live to eat but eat to live. The cook is the chief executioner of King Death.

In the morning do not say, "I am another day older and so much nearer the end"—say "I feel one day younger."

How can we grow old with all eternity before us! The wise men tell us that in the higher life the good ones always appear in the vigor and beauty of mature manhood and womanhood.

What difference makes it if this old suit of ours grows a little shabbier? We shall soon wear a new and better one.

Be as a child, live simply and naturally, steer clear of too much money and too much worry.

Cultivate the spirit of content; nothing ages the face and furrows the brow so quickly as nagging discontent, suspicion
and jealousy.

Before going to sleep, throw off all the cares and anxieties of the day and attune your physical, mental and psychical vibrations to harmonies of rest and peace and love.
PART V

SECTION XLII

FIRST AID IN ACCIDENTS

A person in possession of a clean, healthy, supple body as a result of natural living and treatment, is not nearly as likely to suffer injury from accidents or to develop chronic after effects resulting from them as one whose body has lost its natural elasticity, keenness of sensory organs and recuperative powers through unnatural habits of living and the resulting Pathogenic conditions. This is well known to physical examiners for accident insurance concerns. When a body is in a pathogenic condition, a slight scratch may be sufficient to cause serious blood poisoning or a bruise or fracture may result in necrosis or tumor formation.

Natural methods of treatment are as efficient in giving first aid as in the treatment of acute and chronic diseases, though it may be necessary in serious cases to procure without delay the aid of a surgeon or trained osteopath, chiropractor or neurotherapist in order to examine for internal injury or to correct sprains, dislocations, fractures or other mechanical lesions. However, any layperson possessed of ordinary intelligence and common sense can apply the first aid methods herein described.

In many instances, natural treatment applied in time will greatly ameliorate the suffering and establish the best possible conditions for perfect recovery. The old time drug treatment which was held to be indispensable in cases of accident is as useless and harmful under these conditions as in the treatment of acute and chronic diseases. Much experience in all kinds of emergencies has convinced me that this is true.

In case of an accident it is of primary importance not to become excited and thereby to lose presence of mind and self-control. It is only by remaining cool and relaxed that one can think clearly and decide quickly upon the best course to pursue.

In first aid as well as in acute diseases the quickest and best results are obtained by hydropathic and manipulative treatment. It is, therefore, necessary for the student of emergency work to thoroughly study the methods and applications described under those headings. In order to facilitate quick and ready reference I shall treat the various occasions for first aid in alphabetical order.

1. Alcoholism. Acute alcoholism may result in complete collapse and stupor. It has frequently happened that a person
found in an insensible condition in a public place is mistaken for a drunkard in a stupefied condition, and carted off to a police station, when in reality he is suffering from injury, -a stroke of apoplexy, sunstroke, heat prostration or from some other serious physical disorder. In order to prevent such mistakes, which might easily result in the death of the sufferer through lack of proper care, it is necessary to smell the breath, which, in cases of alcoholism, will immediately tell the story.

a) The best treatment for alcoholic stupor consists in brisk cold rubs, followed by good massage and neurotherapy treatment, calculated to stimulate and to revive the activity of the brain and nervous system. An enema of warm, normal salt solution is also very beneficial. When the patient revives, half a cup of black coffee with lemon juice will act as a mild heart stimulant.

b) Delirium Tremens is a form of acute mania brought about through temporary paralysis of the brain centers which are the seat of reason, Will power and self control. The lower animal emotions are running amuck and in many such cases various forms and symptoms of abnormal psychism prevail. The horrible experiences and visions of people in this condition are not always delusions and hallucinations but frequently are the result of clairvoyance and clairaudience on the lowest spiritual or astral planes, the purgatories and hells of the theologians.

The various phases of abnormal psychism are fully treated in Volume IV, Eugenics. This abnormal functioning of the sensory organs of the spiritual body is brought about through the temporary paralysis of the sensory organs of the physical body;

In order to prevent complete collapse it may be necessary to give at increasing intervals and in decreasing doses, alcoholic liquor, coffee, tea or other light stimulants to revive and strengthen the animal magnetism of the physical body. Tincture of passiflora administered every two or three hours in from ten to twenty drop doses is a good non-poisonous vegetable tonic. Meat broth, Tartar sandwich and other flesh foods may be given until the patient has recovered from the abnormal psychic condition.

The hydropathic treatment consists of cold rubs and cold douches, wet packs and cooling sitz baths. Massage and neurotherapy treatment is of great importance in such cases, not only for its mechanical but also for its electromagnetic effects.

Epsom salt or sea salt rubs also have a positive magnetic effect upon the system. Hot bathing, bromides and other "sedative" measures only aggravate the condition because they have a weakening, benumbing effect. Those who apply such sedative remedies forget that delirium tremens and other maniacal conditions are the result of weakness, exhaustion, and of a benumbed and semi-paralyzed condition of the brain.
and nervous system, and that, therefore, tonic, energizing
treatment is required instead of benumbing, sedative remedies
and applications.

When the patient has recovered from the effects of acute
alcoholism he should undergo thorough systematic natural
treatment in order to eradicate completely the craving for
alcoholic stimulants. We have treated and permanently cured
many victims of the drink habit who had undergone all sorts
or drink cures without permanent results. As drug cures for
the drink habit work on the principle of "poison kills poison".
It is Beelzebub against the devil. While drugs may
temporarily kill the craving for alcoholic liquors, the results
thus obtained are not permanent. As the effects of the drug
treatment pass off, the old craving returns and the drugs
themselves have a weakening and deteriorating effect upon
the system. Such Cures do not influence the moral nature.

Natural treatment with its "back to Nature" life, its pure
food diet, and Its educational influences through daily lectures
and suggestive treatment, arouses higher ideals, strengthens
will power and self control, and thus overcomes in a natural
way the desire for alcoholic stimulants as well as habit
creating drugs. It accomplishes this, not by the introduction of
other poisons but by the purification of the organism and by
the presentation of higher and purer ideals. One who, after
such physical, mental and moral regeneration, has tasted the
sweetness of the natural life will never again crave the gross
deceptive gratification afforded by indulgence in alcoholic
liquors and habit-forming drugs.

Strict adherence to a natural regimen for three or four
months will take away all desire for alcoholic or drug
stimulation. Patients have confessed to me that they did not
backslide on account of an irresistible craving, but through
careless surrender to temptation. Self control must be
strengthened by educating the moral nature. Antidotes. See
Poisoning, no 26.

2. Apoplexy. Apoplectic stroke and the resulting paralysis
are caused by the breaking of one or more blood vessels in the
brain. If the hemorrhage occurs in the right brain hemisphere,
the left side of the body will be affected by paralysis on
account of the crossing of the nerve tracts in the medulla and
spinal cord. If the hemorrhage occurs in the left brain half, the
right side will be affected. The extent of the paralysis depends
upon the amount, of damage done to the brain centers in the
area affected by the hemorrhage. The breathing is labored and
stertorous, the face is flushed and purple in color, the features
are twisted and drawn to one side, the pupils of the eyes are
usually dilated.

a) The head and shoulders should be slightly raised. Quick,
cold salt rubs followed by stimulating manipulative treatment
will draw the blood away from the brain into the surface and
extremities. A lay-person can give the extremities and fleshy
parts of the body a good, thorough kneading, rubbing and
stroking, but a trained masseur or neurotherapist should be procured as quickly as possible to complete the treatment.

b) Wet packs applied to the body and, the extremities will draw the blood away from the congested brain area. A warm normal salt enema (Sec. XVIII, No.4) will help to establish normal circulation. A hot mustard bath applied to the feet or, better still magnetic treatment (p.397) will divert the blood into the lower extremities.

c) After consciousness has been restored, the patient must undergo thorough, systematic natural treatment in order to eliminate from the system the, pathogenic materials which have caused high blood pressure and the hardening and occlusion of the blood vessels in the brain and all through the body, and which brought about the hemorrhage and resulting paralysis. **No alcoholic or drug stimulants should be given because they increase blood pressure to the brain.**

d) In cases of **concussion of the brain, apoplectic stroke, or of hemorrhages from the lungs or stomach**, the patient must not be transported in a vehicle because the jolting might aggravate the condition. The sufferer must be carefully carried on a stretcher.

Of the many patients we have treated after a first apoplectic stroke, not one, as far as I can remember, has suffered from a second attack, provided of course there has been careful adherence to natural ways of living.

**3. Artificial Respiration** In many kinds of accidents, such as drowning, strangulation, asphyxiation by poisonous gases, and in serious cases of fainting and stupor, it may be necessary to resort to artificial respiration in order to restore normal breathing. There are several good methods for this purpose.

a) Quickly remove the clothing from the upper part of the body; lay the patient prone upon his stomach, place a small wad made of clothing or any other material at hand, under his forehead in order to elevate nose and mouth sufficiently to allow free breathing.

The operator knees athwart the legs of the sufferer and places his spread hands on both sides of the small of the back and then exerts gentle but steady pressure, thus compressing...
the lower ribs and chest; he then gradually releases the pressure, allowing the lungs to fill with air. This alternating compression and relaxation of the chest must proceed at the same rate as the normal tempo of breathing, which is about fifteen breaths to the minute in adult life and a little more than this in childhood. With adults, therefore each complete movement in artificial respiration should consume about four seconds including expiration and inspiration, while in children it should consume about three seconds.

b) The same method may be applied while the patient is lying on his back. Make a roll of clothing and shove it under the small of the back so that the head lies lower than the chest. Then kneel astride of the hips, place both hands, fingers spread as far as possible, on the lower ribs below the nipples of the breast and count slowly one, two, three, four; while counting one and two, compress the lower chest gently but firmly and relax the pressure while counting three and four. Continue this alternating compression and relaxation until normal breathing commences (provided life is not extinct). A sudden trembling and heaving of the chest and flushing of the face will indicate when natural breathing commences. While compressing the chest, the operator should at the same time apply strong vibration. This is accomplished by vibrating the hands loosely and vigorously from the wrist joint. The slow, regular counting corresponds to the tempo of regular normal breathing.

c) (Fig. 25a, b, p.385) Another, more commonly applied method of artificial respiration, is the following: The patient lies upon his back; a small roll of clothing or other soft material is placed under the small of the back in order to raise the chest and to facilitate expiration. Inspiration is induced by raising the chest through bringing the arms above and back of the head; expiration is produced by returning the arms downward and in an outward, circular movement to the sides of the body, doubling them at the elbows and pressing the forearms on to the chest (Fig. 25 b). Compression must be followed by relaxation. This alternating compressing and releasing or raising of the chest should also be continued at the rate of fifteen complete movements to the minute for adults and twenty for children, or it may be regulated by counting as in the operation previously described.
The first method (a) is to be favored because it prevents the falling back of the tongue into the throat and because it facilitates the escape of water, mucus or froth from the mouth. This is especially important in cases of drowning when the lungs are more or less filled with water.

d) (Fig. 26) The best method for facilitating the escape of water from stomach and lungs is the following: Lay the victim prone upon his face, stand athwart his body, place your hands under his stomach and raise him at short intervals, thus partially doubling the body upon itself. This compresses the internal organs and facilitates the discharge of fluids through the mouth.

4. Asphyxiation or suffocation is a condition of unconsciousness and insensibility resulting from suspended respiration. It is caused by a deficiency of oxygen in the system and an excess of carbon dioxide. This may be
produced by strangulation, as in hanging, by smothering or internal obstruction, as in choking, drowning, or by the inhalation of smoke or poisonous gases.

The treatment consists, first in artificial respiration described previously; and, secondly, in restoring the circulation of the blood and nerve currents. This is best accomplished through hydropathic and manipulative treatment described under acute alcoholism. The revival of an asphyxiated person may require long continued effort. Cases are known where by three or four hours of persistent effort, people have been revived after hanging or other forms of strangulation or suffocation.

a) The victims of carbon dioxide asphyxiation die because this gas is heavier than oxygen and therefore does not allow this life-sustaining element to enter into the lungs and tissues of the body. A pulmotor may help to force the oxygen into the lungs and to expel the CO2.

b) While rescuing a person from a room filled with smoke or poisonous gases, a wet handkerchief or other piece of wet cloth should be tied over the mouth and nostrils. Breathing should be restrained as much as possible. Care must be taken not to strike a match as it may explode the hydrogen gas. The windows should be opened or broken at once. This will enable the life-saver to take an occasional breath of fresh air while trying to find and to remove the victim of asphyxiation to the outer air.

5. Bandages. When bandaging wounds, fractures or other bodily injuries, care must be taken not to apply the bandage too tightly. This might seriously interfere with the circulation, especially if swelling develops in the injured parts.

a) Triangular Bandage. One of the most useful bandages in accidents is the triangular bandage. This may be prepared from any square piece of cloth by folding it diagonally in the shape of a triangle. Figures 27, 28 illustrate the application of the triangular bandage to a broken forearm Figure 29 illustrates other uses of this bandage. Fold a square piece of
muslin or other material into triangular form and place against the body underneath the injured arm. Point A is drawn over the uninjured shoulder; point B is brought up over the injured arm and shoulder and knotted or tied to point A behind the neck.

![Fig. 29](image)

The projecting flap D is folded over the elbow and fastened with a safety pin. This supports the arm in a comfortable position.

The inner surface of the hand must be turned inward and the thumb upward. Fig. 29 shows the application of the triangular bandage to injured hands and feet.

**b) Figure Eight Bandage.** Fig. 30 illustrates the Figure Eight bandage applied to hand and foot. A long bandage, three or four inches wide is applied with its center to the injured part. The ends are then drawn crosswise around the wrist or ankle and knotted or pinned with safety pins.

**c) Roller Bandage** Figures 31, 32 illustrate the application of the roller bandage. This bandage may be from a few feet to a few yards in length and of any width best suited for its purpose. The bandage is first rolled up either in a single roll or in two rolls from each end (Figs. 31, 32). The single roll bandage is rolled up from one end and applied by unrolling from one end. It should be applied by winding smoothly and evenly around the injured part, but this is possible only when the part is of even thickness. If the injured part is of uneven thickness, as in the case of an arm from the wrist upward or a leg from the ankle upward, the bandage in order to be applied smoothly and firmly must be reversed upon itself. This is done by placing the thumb upon the bandage where it is to be folded back upon itself, as illustrated in Fig. 31.
d) **Double Roll Bandage.** The double roll bandage is applied with its center over the injured part; both ends cross in the back and are then wrapped around the part in opposite directions. (Fig. 32, no 5c))

e) **The T Bandage** has been described under Sec. XV, No.18.

f) **Head Bandage.** Bandages suitable for injuries to the head or for holding in place compresses to the head are applied as shown in Fig. 33. One bandage is drawn over the head to point c and fastened under the chin at a. The other bandage, no 2, is drawn over the back of the head and the base of the skull, and fastened over the forehead.

g) **When the chin or lower jaw is injured**, bandage (a), which supports the chin, is knotted on the top of the head. Bandage (b) is applied over the chin and knotted at the back of the neck. (See Fig. 34.)

6. **Bites** by snakes, dogs, cats or by persons in an enraged or maniacal condition, should be sucked out immediately if they can be reached, by either the victim himself or by a friend. The mouth of the one who performs this operation must not contain wounds or abrasions and should be thoroughly cleansed with water after each withdrawal of blood. The wound, if necessary, should be widened by an incision and
cleansed with dilute lemon juice. Immediately after this there should be applied a wet bandage or wet pack.

The elimination of any possible infection must be promoted through fasting or raw food diet, manipulative treatment and all other natural methods described in this volume. Of special importance in this respect is the bed sweat bath followed by cold ablutions.

In cases of snake bites, never administer whiskey or other alcoholic liquors, nor stimulating drugs. This is not only absolutely useless but decidedly harmful and dangerous. According to reliable statistics, less than eight per cent of people bitten by rattlesnakes or other poisonous reptiles die from the effects of the venom even though no whiskey is administered. On the other hand, many cases undoubtedly end fatally on account of the whiskey treatment. Excessive stimulation is always followed by corresponding depression and frequently by complete collapse. This is most likely to occur when large quantities of the fiery liquor are poured into people who are not accustomed to its effects.

7. Bruises, Bumps and Contusions. These are treated best by the application of wet packs or clay packs. See Sections XV and XVI.

While bruises and bumps do not bleed externally, the torn blood vessels may bleed internally and cause red or black discolorations. Such internal hemorrhage can be best arrested by firm pressure applied around the affected area; that is, by pressing some hollow object such as a spoon or a cup firmly around the bruise. The cooling packs or compresses will allay any tendency to inflammation or suppuration. Raw beefsteak applied to bruises acts in a manner similar to wet packs.

8. Burns and Scalds. When the clothing is afire one should not run about excitedly, as this will only fan the flames to greater intensity. The best way to extinguish the fire is to throw oneself prone upon the ground and smother the flames by rolling. Rugs, blankets, pieces of clothing or any other material within reach may be used by the victim of the accident or by those who are trying to aid him, to smother and to extinguish the flames. Rolling on the floor prevents also the inhalation of the flames or smoke and the burning of face and hair.

While removing the clothing from a body injured by burns or severe scalds, do not try to tear it off by force, but cut around the places where the clothing adheres to the flesh.

The best treatment for burns and scalds consists in applying a mixture made of ordinary baking soda (bicarbonate of soda) and ordinary boiled oil (linseed oil) or olive oil. This simple remedy which can be procured in almost any household, is of wonderful efficacy in the healing of burns and scalds. It allays pain even in severe and extensive sores and prevents the formation of blisters while greatly facilitating the healing
process. The alkaline sodium neutralizes the poisonous acids which form in the sores and the oil keeps the flesh in a softened condition and prevents caking and cracking.

In cases of very extensive burns or scalds, immersion under water of body temperature or slightly below, has been found very beneficial. In such cases the patient may remain suspended under water in a hammock for days or weeks at a time until the sores are healed sufficiently to allow exposure to the air.

Burning of the eyes and face by strong acids, fresh slaked lime, etc., is best treated by the immediate application of the olive oil and baking soda mixture.

For the treatment of shock due to scalds or burns, see 'Shock'.

Carrying an unconscious person (see Transporting an Injured Person, p.417).

9. Choking. Infants and children frequently choke as the result of swallowing small playthings or other foreign objects. Adults may choke from getting fish bones stuck in their throats or trying to swallow large pieces of meat.

If the patient is a child, place him face downward over your lap, and slap him vigorously between the shoulders. If this does not remove the obstruction, then compress the nostrils, which forces him to open the mouth and throat widely, introduce the fingers of the other hand quickly into the throat and try to grasp the obstructing object. If this is not possible, tickle the palate with a feather, a finger, or with a handkerchief rolled to a point. The tickling will cause coughing or hawking which may dislodge the obstruction.

An adult may throw himself over a chair or table, the head hanging downward, while another slaps him vigorously between the shoulders or, if necessary, performs the operations described in the previous paragraph.

10. Convulsions. These are due either to congestion of the blood in the brain, to abnormal pressure of gas on the heart, or to excessive irritation of the brain or nervous system by toxic substances.

The treatment must be adapted to the individual condition. Most of these have been described in Vol. V under Epilepsy, Uremia poisoning and other forms of diseases.

a) For first aid the patient should be placed in a recumbent position with the head slightly raised. Alternating hot and cold fomentations are most effective for drawing the blood or irritating toxins from the affected area into the surface. The patient should sip hot water mixed with a little lemon juice. An enema of normal salt solution and of blood temperature should be administered as soon as possible. Wet packs applied
to the neck, trunk or extremities will also draw the blood into the surface and thus relieve inner congestion and promote elimination of toxic substances. A full hot bath of body temperature of from ten to fifteen minutes duration may give quick results in serious attacks. This should be followed by a brisk cold saltwater rub.

In convulsions of infants the body first becomes cold and rigid, then the skin breaks into a clammy perspiration, the pulse is weak and rapid. This is followed by convulsive movements and later by a semi-comatose condition which usually passes into a natural sleep.

After the first aid measures herein described have given temporary relief the underlying causes must be overcome by natural methods of treatment

b) Uremia convulsions frequently occur in the course of Bright's disease and of diseases which cause prolonged retention of the urine in the bladder. In such cases it is imperative to increase the activity of the skin in order to compensate for lessened elimination through kidneys and bladder. The best way to accomplish this is to apply the bed sweat bath described under Sec. XIV, No. 5, p. 143.

Sufficient hot water bags, bottles, or heated bricks must be placed outside of the whole body pack and under the outer blanket covering so as to produce free perspiration. The patient remains in the pack from fifteen to thirty minutes, as long as he can endure it.

After the removal of the pack he is quickly rubbed down with cold water, either in a bathtub, spray room or in bed. He is then covered well with blankets in order to induce free "after perspiration". This procedure is repeated as often as the patient can endure it and react to it properly. After the pack has been applied, the patient should drink freely of hot lemonade made with brown sugar or honey. This will promote free perspiration.

Expert massage and neurotherapy treatment should be given to stimulate the circulation, to promote the elimination of morbid matter and to correct spinal or other mechanical lesions. Juniper berry tea (Sec. XIX, No. 5) will stimulate the activity of the kidneys. Fasting is imperative. It must be extended for days or weeks, according to the nature of the disease and back of the convulsions. In cases of serious ailments such as Bright's disease, inflammation of the bladder, subacute and chronic prostatitis, the fasting must be followed by raw food diet for weeks or months at a time.

Hot, normal salt enemas should be given to cleanse the lower intestines and to stimulate the vital activities.

For treatment of Epileptic convulsions see No. 14, p. 398, this Section.
11. Cuts and Wounds. Small cuts or wounds should be thoroughly cleansed with warm or cold water and then treated with dilute lemon juice. Air and light are the best of all healers. It is injurious to close cuts with adhesive plaster, because it prevents elimination and shuts off air and light. However, in case of large wounds, the edges may be held together with narrow strips of adhesive tape just sufficient to keep the lips together for healing and to allow drainage. When the bleeding has stopped, the wound should be left uncovered if this can be done without exposing it to the pollution of impurities; or, the covering should consist of just enough porous gauze to protect it.

If the wound should prove painful or become inflamed, frequent bathing in cold water or allowing a stream of cold water to run over it, is the best remedy. If the wound is large enough to cause serious or dangerous hemorrhage, appropriate treatment must be applied. For this see "Hemorrhages", No. 18 (a), page 402.

Delirium Tremens. (See Alcoholism, p.379.)

12. Disease, Sudden Onset of. The simplicity of the natural treatment enables us to apply the most efficient treatment at the sudden onset of any disease whatever. While the medical man has to wait for days and sometimes for weeks before he can find out what the exact nature of the trouble is and apply his specific remedy, the natural therapist gives the most effective treatment from the first manifestation of symptoms. In that way he may be able to abort or to avert many serious diseases which might end fatally if neglected for a few days.

At the first appearance of great weakness, of aches and pains in any part of the body, of increased temperature and quickening pulse rate, a normal salt enema (Sec. XVIII, No. 4, p.165,) of body temperature should be administered in order to thoroughly cleanse the lower intestine. This should be followed by a full sheet pack (Sec. XV. No. 7) or by a trunk pack or, if reaction is unsatisfactory, by a full sheet bed sweat bath (Sec. XIV, No. 5, p.143). (See also description in Uremic Poisoning, No. 10. (b) 4 p. 394.)

Fasting must be enforced from the appearance of the first symptoms of malaise or acute inflammatory activity.

If there are signs of poisoning or of severe inflammation of, the stomach and intestines, vomiting should be induced immediately by means of drinking copious quantities of lukewarm water, either pure or mixed with salt or mustard. If vomiting cannot be induced in this way, tickle the throat with a feather or piece of cloth drawn over a sliver of wood. After thus thoroughly cleansing the stomach, allow the patient to drink freely of water mixed with the juice of acid fruits.

Neurotherapy treatment should be given at once to promote heat radiation, elimination of morbid matter, and to correct mechanical lesions.
A few days of such natural treatment will suffice in most cases to restore the system to normal condition. If an acute disease should develop, it will run a much milder end safer course after prompt natural treatment, and the results obtained will be infinitely better than under the old time drug treatment.

Carefully observe the following warnings, though you may find contradictory advice in books on naturopathic and physical and natural culture treatment: In acute conditions never apply hot water applications nor the ice pack; neither give cold water enemas. They are very dangerous, as they may suppress the inflammatory process and bring about fatal collapse. In cases of serious shock or collapse where the vitality is too low to react to cold applications, alternating hot and cold fomentations are in order, and the wet packs may be wrung out of hot water instead of cold water.

If the hands and feet remain cold and bloodless the best remedy for bringing the blood to the extremities is good magnetic massage. After the manipulative treatment, firmly hold the hands of the patient or grasp the feet around the ankles and will the blood to flow into the extremities. The magnetic treatment must be continued until the hands or feet warm up.

The hot bath or hot water bag treatment produces warmth temporarily but is followed, in accordance with the law of action and reaction by cold reaction; therefore the anemic condition of the extremities is only made worse by such hot applications.

**Drowning** (See No. 3, pg 383)

13. **Ears, Foreign bodies in**, locate the foreign body by using an ear speculum and head mirror. Turn the patient on the affected side and use a syringe from below, to straighten the canal, pull the outer ear up and back. In some cases forceps made of fine wire may be necessary. Living insects in the outer canal may be killed by the injection of alcohol or oil and then removed by syringing or by the wire loop. In cases of peas or beans, do not use water; it will make them swell. Use a wire loop or attach a strip of adhesive plaster to the foreign body and pull it out that way.

Foreign bodies in the nose may be removed in a similar manner.

14. **Epileptic Convulsions**. Nothing must be done to check or suppress the convulsion; this would be very injurious. All that can be done during an attack is to place the patient in a comfortable position and to elevate the head slightly. A neurotherapist should give firm inhibitory treatment over the upper cervical vertebrae and at the base of the skull. Immediately apply rectal dilatation.

If the fit occurs in the house, the patient should be exposed to a draft of fresh air. Push the lower jaw forward so that the
lower row of teeth projects over the upper. This will keep the windpipe open and prevent choking and suffocation. Push a piece of wood padded with a cloth, a cork or a rolled handkerchief between the teeth in order to prevent biting of the tongue. The opening of the clinched hands is useless.

After the attack the patient should rest until its effects have worn off. The treatment for the cure of the disease must be administered between the attacks. Two-thirds of such cases that have come under our treatment made permanent recoveries.

**Exhaustion.** (See Heat Exhaustion, p.401.)

**15. Eye Injuries. (a)** Black eye. Caused by external injury, blows, etc. Natural treatment: Cold applications applied immediately will prevent discoloration and will alleviate inflammation.

Burns. See treatment for burns, No. 8, p.391.

**b)** Foreign bodies in the eyes, such as cinders, bits of sand, etc. These are usually found imbedded in the cornea or in the lid. Pull the lid outward and bend it backward over a toothpick, a match or other bit of wood, thus exposing the inner surface. Then remove the obstacle with a bit of cotton if it is imbedded in the lid; or if necessary with a toothpick or sharp instrument if it is located in the cornea. Treat inflammation with cold compresses and cold eye baths.

c) Perforating Wounds. Perforating wounds of the eyes should be treated with cold compresses and cold eye bath. The patient must remain absolutely quiet and not expose the eyes to any strain whatever. If the sight is lost and symptoms of sympathetic inflammation appear in either eye, removal of the affected eye may become necessary, but this will seldom be the case if the cold compresses and the potato compress and cold ablutions are applied faithfully from the start (Sec. XV, Nos. 1, 4, pp. 147, 148). In any case of injury do not use vaseline, atropine or antiseptics.

**16. Fainting—Insensibility.** Find out first whether the unconscious one is alive and breathing. Hold a mirror, piece of glass, bright piece of metal or a feather before the mouth and nose. If the patient is still breathing, the bright surface will be dimmed by the breath, or the feather will move.

**a)** The following is another test for determining whether life is extinct. Raise the eyelid and touch the white of the eye. If life is not extinct, the eyelid will twitch. Observe the odor of the breath. It will indicate such poisons as alcohol, chloroform, ether, etc. If the tongue has been bitten it indicates epilepsy. If the eyes are sensitive to touch and light, there is no brain injury. Unequal contraction of the pupils indicates brain trouble. Pupils contracted to pin points indicate opium poisoning. Slow, weak breathing indicates collapse or shock. Snoring or stertorous breathing and slow, weak pulse
indicates brain trouble. Rapid pulse points to sunstroke. A hot skin and rapid pulse indicate sunstroke or high fever. Cold skin and weak pulse may be the result of fainting, freezing, or of acute alcoholism. High fever should be treated as described under treatment of acute diseases (Sec. VII {pg. 76, 77).

b) If the patient is still breathing, place him in a comfortable position, the head somewhat lower than the rest of the body. Open or cut the clothing wherever it constricts the body, and expose the patient to a draft of fresh air, if in the open, fan the air, over his face.

c) In order to stimulate heart action, apply, alternate hot and cold compresses to the chest; sprinkle or dash cold water over the face and neck; also apply alternate hot and cold fomentations to the, spine. Massage and apply passive movements to the extremities. If the, breathing is very slow and faint, apply artificial respiration (No 3. page 383). Dash cold water on the neck and on the soles of the feet. Give cold salt water rubs, all over the body. Administer a, warm normal salt enema (Sec. XVIII, No. 4, p.165.). Do not try to administer water or stimulants while the patient is unconscious; it would only choke him.

d) When he revives do not give alcoholic liquors or other poisonous stimulants. The reaction might prove fatal. Give sips of fresh water mixed with acid fruit juices, or, black coffee or tea in small quantities; repeat until full consciousness has been restored.

e) Try to find out what caused the unconscious condition. It may be the result of any one of the following causes: Fainting; collapse, shock, asphyxiation by gas; drowning or other means, acute alcoholism, opium, chloroform, ether or other drugs, sunstroke, apoplexy, epilepsy, convulsions, injury to the brain by concussion or fractured skull, or it may be caused by certain diseases of the heart stomach or kidneys. Treat accordingly.

17. Fractures. In case of fracture, a physician or Surgeon, must be secured without delay. In the meantime excessive bleeding may be stopped as described under "Hemorrhages" (p.402). Swelling may be reduced by wet packs and cold ablutions.

18. Freezing. Frozen limbs, ears, nose or other fleshy parts, of the, body should be, rubbed vigorously with ice water, or snow. Great care, however, must be taken not to break the frozen parts; they are brittle and may break easily.

If a person has become unconscious through freezing, he must be taken into a cold room and treated with cold rubs by means of ice water or snow, until the circulation in the various parts is restored. As before stated, great Care must be taken not to break the frozen parts.

If breathing and heart action are very low or imperceptible,
artificial breathing, with due precautions, must be at once resorted to. The individual condition must determine the best method to be employed. When normal breathing commences, place the patient in a cold bed and heat the room very gradually.

When the body becomes warm, rub with warm flannels, but the frozen parts must still be treated with cold applications and snow rubs.

Warm the body from within by giving hot lemonade with brown, unrefined sugar or honey. Black coffee with lemon Juice will stimulate heart action and circulation.

To drink alcoholic liquor in order to keep warm is extremely dangerous. The benumbing after effects of this and other strong stimulants will induce numbness and sleep when wakefulness is necessary to resist the freezing.

19. Heat Exhaustion is usually the result of injudicious diet in summer, excessive clothing, and of working in close, hot, illy ventilated rooms. The principal symptoms are faintness or syncope; a cold and damp skin and a rapid and feeble pulse. When death results it is due to heart failure; but most cases recover. It is not as often fatal is sunstroke.

a) The patient should be removed to a cool place. Hot lemonade will stimulate the heart action; a brisk, cold rub and wet packs, if necessary reinforced by hot water bottles will restore the activity of the skin. (See Bedsweat Bath, Sec. XIV, No. 5, p.143)

b) Both in sunstroke and heat prostration the head should be frequently laved with cold water. If the body temperature is subnormal and death seems imminent, the legs should be wrapped in woolen blankets saturated with hot water. Care must be taken not to scald the flesh. Around the wet blanket wrap several layers of dry sheeting or a dry blanket in order to retain the heat. The patient should take at intervals small quantities of hot lemonade.

Heat Prostration (See Heat Exhaustion, p.401.)

20. Hemorrhages. (a) Hemorrhages from the mouth. When the blood is of dark color and looks as if it were mixed with coffee grounds or food materials it comes from the stomach and the hemorrhage is caused by cancer. If the blood is mixed with food materials but looks bright red, the hemorrhage is caused by ulcers of the stomach. If the hemorrhage is from the stomach, the patient should be placed in a recumbent position. A trunk pack will draw the blood away from the stomach and relieve congestion. The patient should sip at frequent intervals small quantities of cold water mixed with lemon juice, and should be allowed to rest.

b) Hemorrhage from the Lungs. When the blood is bright red and foamy and free from food materials, it comes from the
lungs and is caused by breakdown of the lung tissues. It is not necessarily directly fatal. Under natural treatment of lung diseases, hemorrhage frequently occurs during the crisis periods and is then a form of elimination. In many cases, recovery from tuberculosis has been preceded by copious hemorrhages. The patient should be kept in bed in order to give the disrupted tissue a chance to heal. The treatment must be directed to the underlying disease.

c) Hemorrhages from Cuts and Wounds. If the blood is bright red and comes in spurts, it is an indication that some important artery has been severed and a ligature should be applied without delay above the wound. If on the trunk of the body, pressure should be made above the wound, between it and the heart. Any solid object, a piece of wood, rock or anything convenient, held in position firmly by a bandage or belt will serve the purpose. (Figs. 35, 36.)

d) If the blood is dark in color and flows smoothly, then some vein has been opened and the ligature should be applied just below the wound. (Fig. 37) Any strap, rope or handkerchief may be used for this purpose, but a rubber hose, if it can be procured, is best suited on account of its elasticity. The ligature may be applied more tightly by inserting a stick, pipe or similar object below the knot and twisting it. (Fig, 35.)

Do not try to remove any clots of blood; they are Nature's provision for stopping the hemorrhage. Hemorrhages from large arteries may be stopped temporarily by compressing the blood vessel with the fingers. In order to do this, one must know where to find the arteries.

e) For an injury on the side of the upper part of the head, the temporal artery, must be Compressed with the thumb. This artery is located about three-quarters of an inch in front of the opening of the ear underneath the temporal bone. (Fig. 38)
If the injury is in the back of the head, the occipital artery must be compressed with the thumb. It is located about an inch from the center of the back of the ear. (Fig. 39) The facial arteries can be compressed by exerting strong pressure at a point one inch in front of the angle of the lower jaw. (Fig. 40.) The arteries pass over the jaw at these points. They should be pressed at the same time on both, sides.

The common carotid artery can be reached at a point one and a half inches above the joint between the breastbone and the collar bone. Pressure may be exerted inward and backward. (Fig. 41.)

The subclavian artery can be reached at a point behind the middle of the clavicle or collar bone where the hump of this bone is felt. First lower and draw the shoulder forward, then press downward and backward with the thumbs or with the fingertips of both hands. The pressure must be firm and persistent. (Fig 42.)
The axillary artery can be compressed by first raising the arm, pressing it outward and backward, and then compressing the artery on the inner surface of the upper arm. (Fig. 43.)

The brachial artery passes along the inner border of the biceps muscle. First extend or raise the arm, then press outward and backward. (Fig. 44.)

The radial and ulnar arteries in the wrist may be compressed readily with the fingertips. (Fig. 45.)

The great femoral artery in the upper leg can be reached best in the groin just in front of and a little inside of the femur bone. Compress with the thumbs or by using as many fingers as are needed.

The popliteal artery can be reached by strong pressure in the central part of the ham, applied, while the patient is lying on his stomach, directly downward.

The wounded part should be raised as high as possible.

Cold water is very effective for stopping hemorrhages. If possible it should be allowed to run over the wound in a constant stream. This inhibits the circulation and favors the clotting of the blood. Care must be taken not to run the water directly on the wound as this might prevent the forming of clots. In order to accomplish this it may be well to place a cup or saucer or some other protecting object directly over the wound.
Only boiled or aseptic bandages should be applied to the wound. **Clay or mud must never be applied to open cuts or wounds.** Water mixed with lemon juice applied directly to the wound acts as a natural antiseptic and astringent, thus favoring the clotting.

21. **Hiccough or Hiccup.** This is a spasm of the diaphragm, caused by nervous irritation of some kind. It may be due to digestive disturbances or to irritation caused by systemic or drug poisons. In chronic form we find it frequently associated with mercurial, phosphorus, strychnine and other drug poisoning.

Ordinary hiccough requires little or no special attention. If it persists, one of the best remedies is to continuously sip and swallow water until one or two of the spasms have been missed; anything that will break the regularity of the spasm will stop it. Out of this fact grew the old custom of "frightening the hiccough" by a sudden motion or exclamation.

In its most serious forms, in cases of drug poisoning, we have always succeeded in alleviating and in most instances overcoming the spasms by the natural treatment. Certain neuropathic moves give excellent results.

**Insensibility.** See "Fainting" No. 16, p.399.

22. **Lightning Stroke.** If a stroke of lightning results in shock or collapse, treat as described under "Shock", p.414. If it results in burns, treat as described under "Burns and Scalds" (p.391).

23. **Mania,** A sudden maniacal outbreak, whether the result of an attack of insanity, of acute alcoholism or of great emotional excitation, is best treated by cold applications such as cold sprays, cold sitz bath, hip bath, quick submersion under cold water, or by cold wet packs.

Soothing manipulative and magnetic treatment is very effective.

It is wrong to submerge such patients for hours or days in warm or hot water. Such sedative treatment is as weakening as opiates and hypnotics and will only aggravate the underlying conditions which are always negative in character.

Such patients should have nothing but vitalizing, upbuilding treatment. Sedative drugs and long continued submersion in hot water will only aggravate the negative conditions and make the underlying ailments more chronic and incurable.

24. **Mental Disorders.** At the first appearance of symptoms of mental disorder; the patient should be placed in an institution for natural healing, where surroundings and treatment are favorable for early recovery.
25. Nose. (a) Foreign Bodies in. (See "Ears," p.397.)

b) Nosebleed. Sniff cool water mixed with lemon juice. This has an astringent effect upon the capillaries. Compress the nostrils temporarily, throw the head backward, and avoid vigorous blowing of the nose. Apply hot compresses to the neck at the base of the brain. Repose on a chair or couch, perfectly relaxed, in a sitting position and remain that way until the bleeding ceases. Refrain from any movement of the body. Have someone else catch the running blood in a basin or cloth. This is the best way to facilitate clotting of the blood.

If this is not sufficient to stop the bleeding or if it should grow worse have small plugs of cotton or muslin inserted tightly into the nostrils. However, it must be remembered that the bleeding may be a form of elimination. It often occurs as a form of healing crisis and should, therefore, not be interfered with unless necessary to avoid excessive weakening and collapse.

26. Poisoning. (a) The first thing to be attended to in any case of poisoning, whether or not the exact nature of it be known, is to empty the stomach. This may be accomplished by the swallowing of large quantities of warm water containing the appropriate antidote, and by tickling the palate with the finger or a feather, thus causing copious vomiting. The washing of the stomach must be repeated several times. If mouth and throat are not burned, a rubber tube may be pushed down the throat into the stomach. By means of a funnel, warm water is poured through the hose until it overflows. The end of the hose outside is then suddenly, lowered below the level of the stomach and water siphoned out of it. This may be facilitated by having the patient assume a position prone upon the face during the draining of the stomach.

b) In emergency cases, mustard, common salt or powdered alum may be given as emetics in proportion of one teaspoonful of either to a glass of water. A lukewarm solution of soap in water is a simple and efficacious emetic. If no emetics are available, cold water should be taken freely and vomiting induced by tickling the throat.

After washing of the stomach, white of egg, milk, or sugared water should be given freely. They are soothing to the inflamed membranes and give the poisons something to work on. Blood warm enemas of normal salt solution (Sec. XVIII; No. 4. p.165) should be given repeatedly in order to eliminate the poison from the intestines. When the patient is strong enough bed sweat baths followed by cold ablutions will stimulate elimination through the skin.

c) In corrosive sublimate or other forms of mercurial poisoning, retained rectal enemas of milk or white of, egg beaten up in warm water will help to neutralize the destructive action of the metallic poison.
d) In all cases, fasting, with dilute fruit juices, should be enforced until the system has eliminated the poison and the injured membranes of the internal tracts have been repaired. Where the latter have been severely burned, fruit juices may cause burning pain unless they are very much diluted with water. In the mild dilute form, they will antidote the destructive effects of the poisons.

e) So called antidotes are effective only when administered immediately. The general rule is, against acid Poisons administer water mixed with baking soda or fresh Lime; other good antidotes are white of egg, rich milk or oil. These substances neutralize the acids.

f) Alkaline poisons must be antidoted with dilute vinegar, milk, white of egg and other albuminous substances which neutralize alkaline poisons as well as acid poisons by diluting them and giving them something to work on besides the tissues of the body.

g) Narcotic poisons like opium, morphine, belladonna, digitalis, poisonous mushrooms, ptomaines, alcohol strychnine, etc., cause loss of consciousness, stertorous breathing, redness of the face, cramps and delirium. If the victim of poisoning is unconscious, artificial breathing must be resorted to (No. 3, p. 383), and the neck, chest and other parts of the body should be sprinkled with cold water. A brisk, cold saltwater rub is very efficacious in reviving the vital activities. As a stimulant administer small doses of strong black coffee.

h) Arsenic, phosphorus, Paris green, vitriol, carbolic acid, hydrochloric acid and lye do not as a rule cause unconsciousness, but give rise to violent pains in the oesophagus, stomach and abdomen, followed by choking and vomiting. Some of these poisons burn the lips, mouth, oesophagus and stomach; such burns may be treated with a solution of baking soda or powdered chalk. The treatment otherwise is the same as given for alkaline and acid poisoning.

**In cases of poisoning a physician should be called in as soon as possible.**

i) Ptomain poisoning results from eating putrefying or decayed meats, fish, cheese, ice cream or other animal food products. The usual symptoms are collapse, subnormal temperature and pain in the digestive tract. Nature generally tries to remedy the trouble by vomiting and diarrhoea. Both these forms of natural elimination must be encouraged by the swallowing of warm water in large quantities and by warm saltwater enemas. (Sec. XVIII, No. 4, p.165.)

The treatment of ptomain poisoning is very much the same as that of other forms of poisoning. The stomach and intestines must be emptied and cleansed as thoroughly as possible by induced vomiting and by saltwater enemas, as
described in the previous paragraphs. After that, the patient should drink copious quantities of fresh water mixed with acid fruit juices. This is much better than the taking of poisonous antiseptics.

While the temperature is subnormal, the bed sweat bath by means of the trunk pack or full sheet pack will promote elimination through the skin. When the subnormal condition is followed by inflammation and fever, cold packs and ablutions are in order and the treatment in general is the same as that for acute inflammatory conditions described under Sec. VII; p. 75.

j) External Poisons. Poisons which affect the human body from the outside include poison ivy, poison oak and poison sumac. Poisoning by insects, snakes and rabid animals has been treated under other headings.

Poison ivy and the other poisonous plants above named owe their toxic qualities to an odourless, transparent oil found on the leaves, bark and twigs, which is insoluble in water. These poisons are powerful irritants. Contact of the skin with these poison plants causes insufferable itching, swelling and vesicular eruptions. In severe cases there may be vomiting, colicy pains, fever and delirium. Parts of the body or the entire cutaneous surface may be covered with eruptions.

The U.S. Department of Agriculture recommends the application of a solution of acetate of lead to be applied to the itching skin. This, however, is a powerful suppressant. While the eruption disappears rapidly under this treatment, it drives the plant poison plus the drug poisons into the system, and wherever these concentrate the morbid soil is prepared for chronic disease.

The poison in its outward symptoms, as well as its internal chronic after effects, resembles very closely the psora or itch taint. Its suppression in the acute stages broadens the scurf rim and frequently produces typical itch spots in the iris.

The best homeopathic antidotes in acute and chronic cases are Rhus tox., psorinum or sulphur. The homeopathic rhustoxicana is a trituration of the ivy poison.

The Natural Treatment. First it must be remembered that the itchy, burning eruptions represent Nature's, effort to eliminate the poisons from the system and that therefore it should not be checked or suppressed by any means whatever. The natural treatment includes, everything that will promote elimination of the poison through the skin and other organs of depuration. If water is immediately accessible, a good, thorough scrubbing of the skin with soap and water, or, if in the open, with sand, tufts of grass, or any other, scrubbing material may be sufficient to remove the poison before it will do any harm; at any rate it will greatly reduce the bad effects.

The preliminary cleansing should be followed as soon as
possible by a whole sheet pack or a bed sweat bath, and cold Ablutions. This may be repeated several times if necessary, or followed by partial packs. Otherwise, the treatment is the same as for acute diseases. (Sec. VIII) Fasting and raw food diet are especially beneficial. The cold packs, compresses and ablutions are the best means for allaying the intolerable itching and burning.

k) Antidotes for Acute Poisoning

By **Lead**: magnesia, soda or chalk water.

By **phosphorus**: thick liquid gum; white of egg; flour; bread magnesia and cold water, for the purpose of enveloping and isolating the poison. Do not give milk or liquids containing alcohol or oily matter.

By **caustic acids, such as sulphuric, muriatic, carbolic or nitric acid**: large quantities of soap, salt, chalk, limewater or milk.

By **copper and verdigris**, frequently contracted by foods or drinks prepared in copper vessels or by drinks from soda water fountains when the copper has become exposed through the away of the zinc lining: dilute white of egg; milk; water mixed with honey or sugar.

By **Iodin**: starch or flour paste.

By **nitrate of silver**: strong saltwater solution; white of egg.

By **oxalic acid**: chalk or lime water.

By **strychnine**: meat burned to a cinder; decoction of acorn coffee; tan or gall apple.

By **arsenic**: warm milk; sweetened water.

**Scalds.** (See Burns p.391)

27. **Seasickness.** The unpleasant sensations accompanying this disorder are undoubtedly caused by a disturbance of the center of equilibrium in close proximity to the, left ear, which in turn affects the entire nervous organism and especially the nerves supplying the digestive organs; causing intense nausea and vomiting.

So far no effective remedy has been discovered for this peculiar disorder. The following directions have in many instances either prevented or greatly alleviated its Symptoms.

Those who intend to travel on the sea should prepare themselves by a brief fast and light raw food diet. This should be continued on board ship. The heavy, rich, greasy foods served in overabundance on board of seagoing vessels undoubtedly have much to do with bringing on the gastric disturbance. The invigorating effects of a sea voyage might be greatly enhanced by a prolonged fast beginning a day or two
before taking passage and extending for a week or more, according to the vitality and recuperative powers of the individual.

The best remedy, aside from these dietetic measures and according to my experience the most efficient, is getting into harmony with the motion of the vessel or car. Many times outside patients have come to me saying they could not continue coming for treatment because the benefits were offset by nausea and vomiting caused by the shaking of the cars. I have instructed the sufferers from ear sickness as follows:

Instead of tensing yourself physically and mentally against the violent vibrations caused by the rolling of the vessel or car, relax completely. Do not oppose and fight the motions but let yourself go with them. A good way to do this is to hum a tune in harmony with the oscillating motion of the ship or car.

In many instances the very first trial of my remedy has given relief and after a few attempts no discomfort whatever was experienced. Those who are naturally immune to car or seasickness probably practice this form of relaxation and rhythmic adjustment unconsciously.

It is another proof of the truth and practicability of the maxim of the Master, "Resist not evil". Those who most fear this form of evil and tense themselves against it are most affected by it, While the person who thoroughly enjoys sea travel and to whom the rolling of the vessel is a pleasure naturally relaxes to it, enjoys the sensation, and therefore feels no discomfort.

28. **Shock** is characterized by collapse and frequently by loss of consciousness. It may result from excessive loss of blood or physical injury, or it may be caused by emotional depression resulting from mental and nervous excitation such as sudden fright, grief, anxiety or anger. In many instances it is the shock rather than the actual physical injury which causes death.

If the collapse is due to haemorrhage, this must be stopped as quickly as possible (see p.402). Cool behaviour and reassuring suggestions are necessary to dispel fear and anxiety. The same tonic treatment must be administered as described under fainting, unconsciousness, etc., p.399.

**Signs of Life.** (See "Fainting", p.399.)

**Snake Bites.** (See "Bites", etc., p. 390.)

29. **Sprains, Strains and Dislocations.** Sprains and dislocations of joints must be attended to as quickly as possible by a competent physician, preferably a neurotherapist, osteopath or chiropractor. If, however, a physician is not immediately available and the injury results
in swelling, then cold packs must be applied to reduce the inflammation and to facilitate the adjustment.

If swelling, or pain, make it impossible to remove parts of the clothing or the shoes and stockings, these should be cut away with a sharp knife. The affected part must have absolute rest before and after the adjustment. Do not apply hot applications of any kind.

30. **Sunburns**, which are frequently the result of imprudent exposure in the sun-baths, are best treated by cold compresses and cold ablutions or by the olive oil and soda mixture.

31. **Sunstroke.** Sunstroke is caused by exposure to the direct rays of the sun in a heated atmosphere. Loss of consciousness is caused by the direct action of the sun's rays upon the brain and the cardiac and respiratory centers in the medulla.

   a) The onset is sudden. The most prominent symptoms are unconsciousness, pallor, feeble pulse and rapid failure of the heart and respiration. Death is common, recovery often only partial, leaving the brain permanently injured.

   b) Under the natural treatment few cases end fatally. The patient should be quickly undressed and cold water poured all over his body, also over the head. This should be followed by brisk salt water rubs; or the body should be wrapped in a wet sheet which must be kept wet by pouring cold water over it from time to time.

If collapse has taken place and vitality is greatly depressed, the patient must be put to bed and well covered with blankets so as to produce a warm reaction.

32. **Thermic Fever** may arise by night or by day through exposure to artificial or solar heat.

   Premonitory symptoms are malaise, nausea, diarrhea, giddiness, sleeplessness, after which the temperature rises quickly to 108 to 110 deg F. or even higher. Prominent symptoms are lividity of the face, dispnoea and delirium. These are often followed by coma and death within a few hours. It recovery takes place it is slow and incomplete.

   Cold, wet packs, followed by cold ablutions, must be applied. The drinking water should be cool and mixed with acid fruit juices. (See the usual treatment for acute diseases, Sec. VIII.) Under natural treatment few cases end fatally.

**Toothache.** See Section XLIII, No.8, p.430.

33. **Transporting an Injured Person.** To lift or carry an injured person in the wrong way may cause permanent injury or even death; therefore, carefully examine the victim of an accident in order to ascertain whether he has sustained a fracture or serious internal injury.
First aid should be administered at once and on the spot; but if removal is necessary, a stretcher may be improvised out of a board, a door, bedspring, or anything else convenient for the purpose (Fig. 49, p.418). Care must be exercised not to drop the injured one. If a patient must be transported by carrying, the following methods will be found practical:

a) If the injured one can walk, let him put his sound arm around your neck and with one hand grasp his hand hanging down from your shoulder and with your other arm firmly support his body. (Fig. 46).

If the patient is unconscious, the following methods will be found most convenient:

b) You may carry the patient in an upright position, placing your right shoulder under his armpit and your right arm around his waist, his left arm back of your own neck and over your shoulder, taking hold of his left wrist with your left hand. In this way you can either help him walk, as previously described, or carry him entirely. (Fig. 46)

c) If an adult person is unconscious and requires immediate removal, it would be impossible for one person to carry him in his arms. In such an emergency, the pick-a-back method is the most practical. Stoop down and place the patient well up on your back; then pass your right arm around his right knee and with the other hand grasp firmly the wrist of his right hand drawn over your left shoulder. In this way he is in a safe position to be carried for a considerable distance and the weight is fairly distributed and balanced over your back and shoulders.
d) The third method of carrying an unconscious person is similar to (c), the only difference being that your right hand after passing around the upper part of the right leg of the patient, grasps his right wrist, drawing his right arm over your left shoulder and firmly across your chest, as illustrated in Fig. 47 above. This position leaves your left arm free for other employment, if desired.

e) If two persons are available for transportation they may support the injured one on their locked hands, while he places his arms about the necks of his carriers. (Fig. 48)

f) Fig. 49, illustrates an improvised stretcher. Two poles have been slipped through the sleeves and body of two buttoned coats. Other improvisations may be made by means of a board, door, shutter, mattress, etc.

SECTION XLIII
CARE OF THE TEETH

1. Disease of the teeth generally speaking, is the result of two causes: First, malnutrition, which causes deterioration and
destruction of the teeth from within; second, corrosion, caused by systemic acids and other corroding substances which attack, from without, the enamel of the crown and the hard covering of the neck and roots.

Dentists and books on hygiene deal almost exclusively with the last named factor. They have a great deal to say about the regular and thorough cleansing of the teeth, and of dental treatment, but seldom mention the influence of food materials, nutrition and constitutional disease on the condition of the teeth.

That this is not as it should be is proved by the fact that animals living on natural food, as well as savage races, and people who live in primitive surroundings and subsist largely on products of the soil not demineralized and devitalized by modem manufacturing processes, have splendid teeth and retain them to the end of life without tooth brush, dentifrice or the attention of a dentist.

The teeth of animals and humans who live on natural food well adapted to their needs, gradually wear off to the gums with advancing age but do not decay or fall out; neither are they troubled with abscesses, pyorrhea or other diseases produced by unnatural and artificial ways of living.

Regular examinations of children in our public schools disclose the fact that in spite of tooth hygiene taught in the schools and enforced in the homes, eighty-five percent or more are suffering from defective teeth. Of 1694 children examined in six clinics during the year 1913 by Dr. A. F. Foot, only eleven were found to possess normal teeth. Dr. Foot reported to the Second District Dental Society of New York as follows.

"The six-year molars of nearly every child were broken down wholly or in part. In many instances the molars were decayed to the gums. So extensive and far advanced were the defects that corrective treatment, even if it were applied, would have been of little value."

2. This almost universal decay of the teeth is caused:

1. by wrong food combinations;
2. by devitalized and demineralized food;
3. by the action of corrosive substances from within and without;
4. by the softness of the food materials and by their excessive heat and coldness;
5. by hereditary and congenital influences.

Examining these pathogenic factors separately we find that the ordinary diet customary in the home, hotel, restaurant and boarding house, consisting almost entirely of cooked foods, is excessively rich in starches, sugars, fats and proteins, but very deficient in the mineral salts. This is true of these foods even in their natural condition, as they come from the soil; but the
discrepancy between negative food elements and positive mineral elements is much greater after the cereals rice, sugarcane sap and beet sap have passed through the modem milling and refining processes. These leave the white flour, polished rice, decorticated corn products, pearled barley, corn starch, white sugar and corn syrup in a devitalized and demineralized condition. Together with the all-important mineral elements, the foods have been robbed also of their vitamins or life elements. What little is left of the vitamins is destroyed and dissipated by boiling, roasting, frying or fermenting.

Unnatural food combinations, which predominate in acid and pathogen producing negative food substances and are very deficient in the acid neutralizing and eliminating mineral elements or alkaline bases, produce excessive amounts of acids, ptomains, leukomains, xanthins and other pathogenic substances which corrode and tear down the outer enamel covering and internal dentine structure of the teeth.

The destructive effect of acids upon bone tissue can readily be demonstrated by submerging a piece of bone in hydrochloric acid. Within a few days the lime salts constituting the solid framework will be dissolved and abstracted, nothing being left but a soft cartilaginous and gelatinous mass. Submerge an eggshell in strong vinegar; within a few days it will be completely dissolved. In similar manner, acids in the blood and mouth fluids, and acids which form in decaying matter clinging to the teeth and in the hollow spaces between them, will gradually destroy the enamel and dentine.

Refined sugars act very much as do acids. Having been robbed in the refinery of their positive mineral elements, the remaining negative elements, hydrogen, carbon and oxygen, by chemical affinity leech the minerals from the bones and tissues, thus causing gradual decay.

The sturdy Scots owe their tall and large boned bodies to the highly mineralized cereal, fruit and vegetable products of their mountain valleys, the soil of which is enriched every season by the mineral wash from the rocky hillsides.

As long as they lived on whole meal barley bread and oatmeal porridge made from homegrown and home milled cereals, they had splendid teeth. During the last few generations, however, since they commenced to abandon their primitive foods for white bread, white sugar and devitalized breakfast foods, dentists have become more numerous among them.

3. Gingivitis and Pyorrhea. These ailments are so injurious, not only to the teeth, but also to the general health of the body, and they are increasing in frequency with such alarming rapidity that they deserve special attention.

Allopathic medical science declares that gingivitis and
pyorrhea, like all other inflammatory diseases, are caused by germs, and has vainly tried to cure these common ailments by the application of antiseptics and germ killers. We find that as usual the germs are secondary effects, that we must look for the true causes in other directions. These are:

1) Lack of exercise for the teeth and the connective tissues which hold them in place.

2) Inflammation of the gums, caused by hyperacidity of the system and other pathogenic conditions.

3) The corroding action of mineral deposits on the teeth.

Dr. Robert Aiston, a prominent Chicago dentist, who for twenty years has made pyorrhea a special study, says he is positive that lack of exercise for the teeth and the connective tissues which hold them in place, is the principal cause of pyorrhea.

In an interview I had with him lately on the subject, he said: "No man living has made a more exhaustive study of pyorrhea than I have, and I am convinced that the principal cause is the predominance of soft, mushy, cooked food in the customary diet of our American people."

The reasons with which he backs his opinions are very convincing. I shall condense them in the following paragraphs.

The roots of the teeth are held in place by ligamentous tissues and these remain strong and sound as long as they are subjected to normal strain from the push and pull exerted by vigorous mastication. When this ceases, as a result of the continuous consumption of soft, cooked foods, then the dental ligaments and other connective tissues begin to weaken and decay. Stagnation and putrefaction set up inflammation, this produces inflammatory exudates rich in calcareous salts and these in turn form seruminal calculi on the roots of the teeth, so called because these mineral encrustation's are precipitated from the blood serum. The doctor showed me a number of teeth which were thickly covered with these rough, earthy deposits.

I fully agree with Dr. Aiston that local stagnation, due to lack of exercise, is one of the primary causes of inflammation and destruction of the dental ligaments, but I believe that this is greatly facilitated and aggravated by pathogenic materials and disease taints in the circulation, and in the very beginning by mineral encrustation's on the surface of the teeth.

Elsewhere I have mentioned that in several cases pyorrhea entirely disappeared after the patients had been cured, by natural methods, of smallpox, gonorrhea, syphilis and other acute, eliminative diseases. Healing crises eliminated the disease taints; raw food diet reduced the "calcareous exudates" and scoured the teeth of slimy and earthy deposits.
deposits. In this connection I should mention that after the adoption of a raw food diet mineral deposits on the teeth at first increase. This is caused by the neutralization of large amounts of acids. But as the acidity, under the influence of alkaline diet, diminishes, mineral precipitation ceases, inflammation subsides, the encrustation's on the teeth are gradually absorbed and the gums have a chance to heal.

Pyorrhea, as well as other chronic ailments, can be cured only by restoring the entire organism to a clean, normal condition.

Gingivitis. The mineral deposits on the crowns of the teeth, usually light, gray in color, are commonly called tartar. Dentists speak of them as salivary calculi, because they are formed by earthy precipitates from the saliva. These tartar deposits may encroach under the borders of the gums, and this, together with slimy, mucoid accumulations, gives rise to inflammatory, destructive processes in the gum tissues. This is commonly called gingivitis. It is the forerunner of pyorrhea. The only difference between the two ailments is that in pyorrhea the mineral deposits form on the necks and roots of the teeth, and that these seruminal calculi, are blacker, harder and more destructive than the tartar on the crowns. The sharp earthy crystals help to corrode the dental ligaments, aggravate the inflammatory processes, and thus in turn increase the inflammatory exudate of calcareous matter. Filthy, putrefying matter could not accumulate around the teeth and under the gums if the food contained sufficient coarse, scouring material.

Thus it will be seen that the two causes, stagnation due to lack of exercise, and mineral precipitation due to hyperacidity of the system, seesaw in the causation of gingivitis and pyorrhea.

The Rational Treatment of Gingivitis and Pyorrhea

It is well enough to scrape from the teeth the earthy encrustation's which cause the gums to recede and to putrefy, but what good does this when the hyperacid condition of the system makes new deposits?

Many people have the idea that they can safely eat meat, eggs and large amounts of starchy foods as long as they consume with them plenty of the mineral salt foods, such as fruits and vegetables. As explained in Vol. I of this series, in Chapter XXIX, this is a mistake. The intake of too much starchy and protein food leads to the excessive production of acids and other pathogenic substances. Though these are neutralized by alkaline mineral elements, more earthy salts are thus formed than can be properly eliminated through the skin and kidneys. These salts collect on the teeth as tartar, or they may form deposits in the joints resulting in rheumatism.

4. In order to prevent these and a host of other acid diseases, it is not enough to adopt a vegetarian diet, but the
intake of vegetables, starches and proteids must be kept within normal limits. How to accomplish this I have explained under the heading of food combinations in Section 1, No. 10, pp. 23, 24.

Normal consistency of the food also has much to do with the preservation of the teeth. The perfect condition of the teeth of wild animals and of primitive man is partly due to the fact that they consume their foods in the natural raw condition, thus giving the teeth plenty of wholesome exercise by the gnawing, grinding and crunching of bones, grasses, raw cereals, fruits and nuts. While savage or primitive people cook some of their food, they use much more raw food than do their civilized cousins.

Cooked food, in which most of the vitamins have been destroyed, is much more prone to acid formation than live, raw food. Physicians and dentists frequently warn against acid and sub acid fruits "because they destroy the enamel of the teeth." This is a mistake. The live organic acids of fruits and vegetables, charged with vitamins, have not a destructive effect upon the bony structures as do the disease producing acids formed by abnormal food combinations and putrefactive processes. The malic and citric acids of the fruits are highly organized and help to dissolve the earthy deposits in the joints, and the tartar on the teeth. (See footnote page 434.)

**Unless the diet contains liberal proportions of raw vegetables, fruits, roots and nuts, which are splendid natural scourers and cleansers, the teeth are bound to deteriorate and decay.**

Even the teeth of cows become loose and fall out when the animals are fed continually on the soft, sloppy, devitalized and demineralized cereal offal of breweries and distilleries.

To begin the day and to end it with the munching of an apple or some other raw fruit or vegetable relish, is the best way to keep the teeth in a perfectly clean and sound condition.

Another reason why dentistry in civilized countries is one of the best paying professions, is the habit of swallowing food and drink, either very hot or extremely cold. Not infrequently the piping hot soups and other viands are washed down with ice water or immediately followed by ice cream, sherbet or other chilled desserts.

The sudden expansion and contraction due to contact with excessive heat or cold causes the enamel to crack and thus exposes the dentine of the teeth to the destructive activity of acids and other corroding substances.

When prospective parents have destroyed their teeth by unnatural practices, how can they expect to produce offspring with sound bones and teeth? When the blood of the mother is utterly deficient in the bone building mineral elements, is it any wonder that the new born comes into the world
handicapped for life with a dwarfed, defective bony framework? The formation of tooth substance begins in the embryo after the sixth week and continues all through gestation. This further reveals how important it is that the food of the mother contain sufficient amounts of the bone and teeth making elements. This is possible only when her diet includes an abundant supply of fruits and vegetables, hulls of grains and other mineral salt foods; classified under Group V of the food Table, page 33.

I have observed in many instances that when the prenatal structure and chemical composition of the teeth is abnormal, natural feeding after birth cannot always make good for the defective foundation. An imperfect, cankered Seed will not produce a perfect tree, even though the soil it grows in contains abundant nourishment.

5. Cleaning the Teeth. By the foregoing I do not wish to depreciate the importance of keeping the teeth in a clean and sweet condition by careful scrubbing several times a day, particularly in the morning and before retiring. If convenient it should be done after every meal.

However, we do not favor for this purpose the use of preparations containing poisonous antiseptics. These are readily absorbed by the tender tissues of the mouth and in time will cause trouble in the body. Practically all tooth powders, pastes and lotions sold in the drug stores contain such deleterious substances. These are not only decidedly harmful, but entirely superfluous because the best tooth wash is fresh, cool water made slightly acid with lemon juice. Brisk scrubblings of the teeth with this natural dentifrice will keep the gums and teeth in clean and sweet condition. This should be followed by rinsing the mouth with fresh water. The scrubbing should be done from above downward and from below upwards. This will tend to pull the gums over the teeth and to cleanse the crevices between the teeth from food particles and slimy accumulations.

Another good treatment is to dip the forefinger into cold water and give the gums, inside and outside, a good rubbing and kneading. Always finish by rinsing the mouth thoroughly with water as cool as the gums will endure.

If there is a tendency to the formation of tartar the teeth may be thoroughly scoured a few times a week with ground pumice stone, whiting or oyster shell, but this must not be repeated too often because it might injure the enamel.

It goes without saying that the teeth should be looked after by a competent dentist at least every six months, and that defects of any kind should be attended to promptly. Many a tooth can be saved by a timely filling, a well fitted crown, or good bridge work. These matters must be left to the skill of the dentist. The better he understands his art, the more economical will be his services in the long run.
6. Foci of Infection and their Suppression. The latest theory of medical science is that rheumatism and a number of other acute and chronic diseases are caused by germ infection from suppurating tonsils and adenoids, from abscesses in the teeth and ulceration and pyorrhea of the gums. These shortsighted deductions are the natural outgrowth of the germ theory and of the local and symptomatic conception of disease.

We find in our institutional work that the aches and pains of rheumatism, headaches and asthmatic spasms, etc., come and go, rise and fall in exact proportion to the increase and decrease of acids and other pathogenic materials in the circulation. I do not deny for a moment that the pathogenic materials in these foci of infection may start or aggravate acute conditions in other parts of the organism, but is it sufficient to suppress the foci of infection with antiseptics and surgical treatment? The question is, what causes the foci of infection, the suppurating tonsils and adenoids, the abscesses in the teeth, the ulcerating gums and jawbones?

Does medical science imagine that the suppression of these foci of infection with poisonous antiseptics and surgical operations solves the problem? Why cannot they see that this also is rank suppression and not Cure? What is the use of suppressing these symptoms of constitutional disease in one place and having them bob up at another place in more destructive form? Of such nature are the great achievements of modern medical science.

7. This latest craze has led in innumerable instances to the pulling out of whole sets of teeth because one or more were abscessed or because of the presence of so-called pyorrhea, which frequently is nothing but a raw condition of the gums induced by encrustation's of tartar on the roots of the teeth. I meet almost daily with people who have been robbed of sound teeth, sometimes of entire sets, on the assumption that it would cure their rheumatism or other constitutional diseases. To their sorrow they find that the cruel sacrifice has brought no relief so far as their chronic ailments are concerned.

Such criminal experimentation is on a level with tearing out sound ovaries with the idea of curing epilepsy or other chronic diseases. I have known of a number of such uncalled for mutilations. In no instance has the unnatural treatment benefited the patient; it has only served to aggravate the chronic ailment and to hasten physical, nervous and mental breakdown.

The constant suppression of symptoms of disease by drug poisoning and surgical mutilations creates chronic invalidism, hereditary disease, and defectives. Is it not more rational to put the system, through natural living and treatment, in such a pure and wholesome condition that it cannot develop inflammation and suppuration of the tonsils, teeth, gums and
jawbones? Such is the practice of the new school of healing.

8. Toothache. One of the most excruciating tortures that man inflicts upon himself by wrong living, is the toothache. All the causes I have enumerated and described help to create it, and avoidance of these causes is the best prevention.

There are two general types of toothache, the acute inflammatory, accompanied by heat and swelling, and the cold neuritic or neuralgic.

a) The acute inflammatory may be due to congestion and irritation of the blood vessels and nerves of a tooth or row of teeth by systemic poisons, in the same manner that inflammations arise in other parts of the system as the result of pathogenic obstruction and irritation. Acute inflammation may arise when the nerve of a tooth becomes exposed through decay of the bony structure. In that case the attention of a dentist may become necessary. But care must always be taken not to cover decaying particles with a filling or crown. The parts to be covered must be carefully cleansed of all materials that might cause further putrefaction.

b) Treatment. The acute inflammatory toothache is best treated by retaining cool or cold water in the mouth until it warms up, when it should be spit out and replaced. At the same time cooling compresses or packs should be applied to the cheek on the affected side. The pack as usual consists of a piece of muslin, folded from three to six times, and wrung out in cold water. The cold compress is then covered by one or several folds or dry flannel or woolen cloth. The compress or pack may be kept in place by one of the bandages described on page 390.

An acute congestive toothache may be greatly relieved by gentle downward massage movements along the veins and lymphatics in the neck. Thorough drainage of these vessels will do much to relieve the congestion in the affected parts. While giving the massage movements, also use your mental power to combine with the mechanical treatment the magnetic effects. Osteopathic, chiropractic and naprapathic treatments prove very effective in many cases.

In serious attacks the local water treatment may be reinforced by a whole sheet pack, bed sweat bath, or body or leg packs followed by cold ablutions (Sec. XV, p. 147). During the night the sufferer may at intervals take a cold rub and go under the bed covering without drying. All these water applications draw the blood away from the congested area into the surface and thus relieve the local congestion and excruciating pain. They also promote the elimination of the pathogenic materials which are the primary cause of the trouble.

If acute inflammation within and around the teeth were always treated in this way it would seldom come to the formation of acute or chronic abscesses. The pathogenic
materials would be absorbed and eliminated immediately.

Of equal importance with the water treatment is fasting. From the first appearance of a toothache, absolutely no food should be taken until it has ceased entirely, and even then the fasting should be continued for a day or two in order to clear up the constitutional condition which caused the local inflammation. Fasting alone in many instances has cured the severest toothache.

I would warn strongly against the use of poisonous pain killers. They only serve to paralyze the nerves and do not in any way remove the underlying causes of the trouble. They add drug poisons to disease poisons and thereby accelerate destruction of the teeth and the gums.

c) Neuritic Toothache. This type of toothache is not accompanied by great heat and swelling as is the inflammatory kind. It is usually caused by the exposure of a nerve, or by the irritating effect of some systemic or drug poison. If caused by defects of the teeth and by exposure of a nerve, proper dental attention is of course indicated.

This type of toothache is much more stubborn and does not yield to treatment as easily as does the acute inflammatory kind. Cold water, magnetic and manipulative treatments give but momentary relief. The reason is that the pain will continue or will return at intervals until the poisonous irritant is removed or until the nerve is killed or protected. Sometimes the jaw bones and cheek bones are more affected by these neuritic toothaches than are the teeth themselves. This is usually due to the action of some irritating poison.

d) Treatment. In these cold, persistent forms of toothache, hot applications sometimes give better relief than the cold applications, though the relief is temporary.

A remedy worth trying when cold treatment fails, consists in the application of a muslin bag partly filled with hot salt and held in place by a bandage. The salt should be as hot as it can be endured.

The only way these neuritic toothaches can be permanently cured is by eliminating the poisons which are at the root of the trouble.

In many cases we have found mercury, iodine, arsenic, quinine, or other drugs to be the real cause of the disturbance.

Elimination of these hidden enemies can be accomplished only by thorough systemic treatment and natural methods of living.

Many dentists are in the habit of using large doses of iodine, arsenic or other powerful poisons for killing the nerves. They should be warned not to use any more of these destructive poisons than is absolutely necessary. If the work
can be accomplished without using them at all, so much the better.

I would also warn strongly against amalgam fillings. The amalgam or silver filling, so called, contains about 50% of mercury. Acids in the blood and in the fluids of the buccal cavity have a tendency to dissolve the mercury and to create bichlorid of mercury and other mercurial salts which will accumulate in certain parts of the body for which they have a special affinity, particularly in the brain and spinal cord. I am aware that such warnings are pooh-poohed and ridiculed by many dentists, but practical experience tells a different story. The blackening of the teeth indicates formation of mercurial salts. In numerous cases, we have observed pronounced symptoms of mercurial salivation, such as metallic taste in the mouth, ulceration about the necks of the teeth, fetid breath and abnormally increased flow of saliva, which did not disappear until the amalgam fillings were removed from the teeth and replaced by gold, or porcelain. Gold filling, whenever it is practicable, is undoubtedly the best of all.

I know skilled dentists who have discovered these facts for themselves in the course of practice and who have discontinued the use of amalgam fillings on this account.

Of late I have met with several cases of paresis which showed distinctly the sign of mercurialism in the iris. Inquiry revealed the fact that these patients were dentists who for many years had been in the habit of mixing the amalgam and alloy in their bare palms. Mercury had thus been absorbed and was responsible for the destruction of brain substance.

Referring to statements made in section XLIII. 1. In the last paragraph I call attention to the fact that acids act differently on dead and living tissues. The hydrochloric acid secreted by the stomach in normal solution does not affect this organ injuriously, while it readily decomposes the stomach of a dead animal. The same principle holds true in relation to the action of fruit acids on dead and live teeth.

SECTION XLIII

WHY GROW OLD?

"What a question," you exclaim. "We grow old because we cannot prevent it; because Nature has decreed it so."

Of course we shall grow old in years but if we live in harmony with Nature's laws we need not grow old in mind or heart nor lose our physical energy and our alertness and suppleness of body and mind long before the expiration of our allotted time. While growing older in years we should grow younger and more robust as far as our intellectual, emotional, moral and spiritual qualities are concerned.

As regards longevity and the possibility of retaining our
youthful qualities to very old age, we meet with two extremes of opinion. Many mental scientists and new thought people tell us in their lectures and writings that it is not impossible to achieve immortality and perpetual youth in the physical body on this earth plane; that we die long before our time because we imagine we must; that a short-lived existence was necessary for animals and human beings in the early stages of evolutionary development, but that now since the physical body has become more perfect the necessity for dying has passed away and that as soon as we can exterminate the old age and death thought which has become race habit, the "last enemy" will be vanquished and immortality and perpetual youth in the flesh will become the common heritage of human kind.

The majority of mankind entertains an entirely opposite and somewhat pessimistic opinion as regards longevity and the preservation of youth. They are convinced that growing old and decrepit, that losing the enthusiasm, beauty and efficiency of youth is inevitable. They argue that growing old or dying young, health or disease, depend upon heredity, environment, colds, drafts, germs and other accidental circumstances over which we have little or no control. One prominent physician recommended the chloroforming of people over sixty years of age. These two opposing views were brought home to me quite vividly some time ago, while attending a lecture by a well-known mental scientist. His subject on this occasion was "Perpetual youth".

In alluring language, scintillating with plausible argument and beautiful metaphor, he proved to his own satisfaction the possibility of perpetual youth and life ever lasting in the physical body. After the audience had given fervent expression to its approval of his lofty idealism, an elderly gentleman in the audience arose and delivered his views on youth and longevity in a pessimistic wail that was taken in shorthand by a stenographer present in the audience.

"This subject of perpetual youth as put forth by our speaker is a beautiful theory. It is a wonderful theory, but I am very clear that it does not work out in life. I do not believe there is such a thing as perpetual youth. It is an ideal belief. You cannot by any process known to human science or human ingenuity turn back the wheels of time or stay them in their revolution."

"This fountain of perpetual youth old men have sighed for, old women have prayed for, and in search for it from time immemorial young women have appropriated their husbands wages and poured their money into the cash box at the drug store; but they have never yet found it."

"It is true that by right thought and right action you can probably postpone old age, but you can postpone it only to a very limited degree. The speaker stated that seventeen hundred people in the United States had reached the age of one hundred years, but he did not tell you how many of them
are paralyzed, how many of them are palsied, how many are more dead than alive.

"He tells you that with advancing age the arm of the blacksmith grows stronger. This is true for a certain time, but its strength reaches its zenith, then it grows weaker and weaker until it hammers no more. Young man, you cannot turn back the wheels of time and you cannot stay their revolutions. The time that is past is laid to rest in eternal sleep; it is buried in the mysterious realm of oblivion.

"Time robs the bridal wreath of its beauty. Time writes wrinkles upon the brow of the aged. You may wreath, garlands and place them around the brow of youth, but the onward march of time sees them wilt and mingle with the dust.

"The birds that sing so sweetly will return in the spring. The flowers will return and bloom again, but, ah, my friends, youth is gone. It is past forever. It never returns, but age is real and forever-perpetual youth is no more than a beautiful dream."

As regards the possibility of life everlasting on this earth plane, I for my part would gently but firmly decline it. The idea of living in the same old place forever and forever is not attractive to my mind. I imagine in time it would become too monotonous.

To me, life is a great school; a school of personal effort for the development of our latent god-like faculties, capacities and powers. This school takes in all there is in the sidereal universe. Its course in length of time is eternity; its classrooms and laboratories are the solar systems and their planets. Whenever we have learnt all there is to learn; all there is to be acquired of knowledge, wisdom and experience in this great school of life, then it will be time for us to die. The only death I know of is stagnation and retrogression. Life is growth; growth is change, continual, perpetual change—senescence and rejuvenescence, as science calls it. Death is only a phase in this continuous process of change.

The majority of mankind look upon death as the greatest evil in life. They think of it with despair and terror. Some commit suicide because they are afraid to die—a strange paradox, inspired by fear, fear of something that is in reality the greatest of all blessings, the birth into a new and brighter world with new life, new youth, new and broader possibilities, after we have acquired all there is to be learned in one brief earthly pilgrimage.

Why grieve for the loss of loved ones who have made the great transit before us? Shall we not be glad to meet them when we arrive on the other shore? If we had to travel on a long journey to a foreign country, wouldn't we be pleased to meet with friends among strangers in a strange land?
Life on earth is only the kindergarten in the great school of the universe. Even the greatest and wisest of men that live on this earth are only in the lower grades of the great Cosmic University. Why should we fear to pass on? Nobody would like to remain in the primary grades all his life when there are so many more interesting, useful and beautiful things to be learned in the higher grades.

One New Thought philosopher argues that immortality in the flesh, or at least a prolonged term of life on this earth, is necessary in order to acquire all there is to be learned and experienced in this beautiful world of ours and in order to permit the law of compensation to work out the great chain of cause and effect.

How much more reasonable and beautiful than this idea of continuous existence on earth is the philosophy of Karma and reincarnation of the ancient wisdom religion. Is it not better to have the arduous training of earth life alternate with vacations in the spirit land, and to return oblivious of previous existence's with their depressing burdens of errors, sins and sorrows? Thus death on one plane of life becomes birth into another, and vice versa.

In this continuous change from the old age of one life to youth in another life, lies for me the true solution of rejuvenescence, of immortality and of perpetual youth.

If we look upon life from this higher and brighter viewpoint, how can we grieve at growing old? How can we fear death? Those who are in conscious touch with life on the spiritual planes tell us that beings of high spiritual development appear in a condition of youthful maturity, combining the wisdom of millenniums of spiritual and celestial existence with the beauty of perpetual youth. It is not knowledge, wisdom and experience that causes premature senility and death, but wrong thinking, feeling and doing. Aside from unnatural physical habits of living, nothing promotes senile decrepitude like fear of disease and death, bred through ignorance of life's great laws.

He who looks at life from the higher and brighter viewpoint enjoys advancing life in ever greater serenity of soul and happiness of spirit. He rejoices in ever greater expansion of mind and deeper understanding of life's mysteries. He is justly proud of every year added to a life of usefulness to himself and to his fellow beings. Such a one has only pity for the pessimist's wail previously recited. Such gruesome thinking and feeling is the very essence of black magic that ages and stiffens the body and pencils wrinkles on the brow.

To grow younger as we grow older, we must practice white magic. The body is an electrotype of our mental images. Physical matter convolutes to the mental and psychical or soul pattern. "As a man thinketh in his heart, so is he," or as Gautama Buddha expressed it, "I am today what my past
thoughts and feelings have made me."

See yourself in your mind's eye as always beautiful, vigorous and active, as in the prime of youth, for "A man is never older than he feels, and a woman never older than she looks." "But", you ask, "how shall we keep our looks young?" That is simple. Bathe daily in the sparkling waters of serenity of mind and of cheerfulness and in the milk of human kindness. Learn how to relax completely in body, mind and soul and never entertain discordant and destructive thoughts and emotions.

Physical Causes of Senescence

Mental magic alone, powerful as it may be, is not sufficient to prevent the aging of body and mind. We must also live in harmony with the laws of the physical. No matter how good a watch you have, if you allow it to fill up with dust, dirt and corroding acids, it will soon lose time and finally stop entirely. This is exactly what happens to the human clock when it "grows old".

As philosophy has two divergent opinions concerning the prolongation of life, so has physical science two theories concerning the causes of senescence or senile deterioration. According to one of these theories, the animal and human being is endowed at birth with a certain amount of vitality, or with a certain momentum of vital force. When this is gradually spent in course of time our powers begin to wane; as a result of lowered vitality the vibratory power to expel waste declines; blood and lymph vessels become obstructed, joints stiffen, brain and nerve matter hardens and we grow old and decrepit.

Certain facts in Nature favor this viewpoint. Even under the most favorable conditions in the freedom of Nature animals live only to a certain age limit. Each species and family of creatures seems to have its own allotted lifetime or age limit. When this limit is reached they suddenly decline and die. I say "suddenly" advisedly. They do not spend a third or a half of their lifetime in getting old and in dying like the average human being. They retain their full vigor and beauty of form almost to the end of life. It is of rare occurrence that a hunter kills an animal that is found to be diseased or deformed. Among antelope, deer and elk the oldest bucks are usually the leaders of the herd. In order to maintain their supremacy they must fight and vanquish their younger rivals.

So human beings when living the natural life, physically, intellectually, morally and socially, will reach the no limit fixed by Nature for the human species in full possession of their faculties, capacities and powers, and will depart from life peacefully. Death will be as painless and sweet as sleep. I believe that in higher reaches of evolutionary development yet to be attained by mankind, the transition from earth life into spiritual life will not mean the passing "through the valley of the shadow" but that human beings will make the transition in
full possession of their waking consciousness.

The opposite theory advanced by physical scientists as regards the causes of senescence, postulates that vital energy is generated by the cells, tissues and organs of the body, and that as these with advancing age deteriorate and disintegrate, vital energy ceases to be generated and the constituent elements of the body become unfit to carry on the vital activities.

Natural Therapeutic philosophy teaches that the physical body is an instrument for the manifestation of the great life force which is divine life, intelligence and creative power. God or Nature evidently does not intend us to live on this earth forever in one continuous stretch of life and therefore has wisely limited the supply of vital force as well as the durability of the physical body in accordance with the laws governing incarnation and reincarnation on the physical and spiritual planes of life.

As before stated, even the healthiest animals living in the most congenial surroundings in the freedom of Nature do not much exceed their allotted span of life, nor do they fall much below it. As a rule, the longer the period between birth and maturity, the longer the life of the animal.

All the different families of mammalia, when living in freedom, live closely up to the life period allotted to them by Nature. Man is the only exception. It is claimed that according to the laws of longevity his average length of life should be considerably over one hundred years, while according to life insurance statistics the average is at present about forty years. This shows an immense discrepancy between the possible and the actual longevity of man.

Even this brief average span of life means for the majority of mankind little else than weakness, physical and mental suffering, premature senility and death. Visiting physicians of the public schools in our large cities report that seventy five per cent of all school children show defective health in some way. Diagnosis from the eye proves that the remaining twenty five per cent are also more or less affected by hereditary and acquired disease conditions. Christian Science says, "There is no disease". Nature's records in the iris of the eye prove there is no perfect health.

These established facts of greatly impaired longevity and universal abnormality of the human race would of themselves indicate that there is something radically wrong somewhere in the life habits of man, and that there is ample reason for the great health reform movement which was started about the middle of the last century by the pioneers of nature cure in Europe and which has since swept, under many forms and guises, all portions of the civilized world.

When people in general grow better acquainted with the laws underlying prenatal and postnatal child culture, natural
living, and the natural treatment of diseases, human beings will approach more closely the normal in health, strength, beauty and longevity.

However, to reach this ideal of perfect physical, mental and moral health, succeeding generations will have to adhere to the natural ways of living and treating their ailments. It cannot be attained by the present generation. Those enthusiasts who claim that they can, by their particular methods, achieve perfect health and live the full term of human life are destined to disappointment. We are so handicapped by the mistakes of the past that the best which most of us adults can do is to "patch up", to attain a reasonable measure of health and to approach somewhat nearer Nature's full allotment of life.

Growing old consists in the accumulation of waste and morbid matter, earthy deposits, destructive acids and alkaloids, causing the stiffening and hardening of joints, bones, veins and arteries and the gradual loss of physical and mental energy.

Do you ever stop to think how this clogging and corroding of the wheels of life is promoted and accelerated by wrong habits of eating and drinking? Food chemistry as taught by the school of Natural Therapeutics clearly shows that excessive use of starchy and proteid foods is the most prolific cause of disease and of premature old age. These classes of foods create in the body a large variety of destructive acids, ptomaines and alkaloids, such as uric acids, sulphuric acid, oxalic acid, indican, xanthins, creatin, etc.

Flesh foods especially favor these morbid accumulations because they are already saturated with all the waste products of the animal carcass. The poisonous xanthins of coffee and tea are almost identical with uric acid. While at first they over stimulate the organism, the second and lasting effect is to benumb and paralyze heart and nerves and to retard elimination, thus causing directly and indirectly retention and accumulation of waste matter in the body.

For these reasons, we of the Natural Therapeutic school realize that the only way to keep the system pure and sweet and its vibratory activities vigorous and harmonious is to reduce in the daily dietary the allowance of starchy and proteid food and to use a larger proportion of fruits and vegetables whose alkaline elements tend to dissolve and eliminate the acid crystallizations and deposits in the tissues.

This becomes more imperative as we grow older. A young and growing body, physically active in play and sport, needs a great deal of sugar and of proteid to furnish fuel and to feed and repair the rapidly growing and changing cells and tissues.

When we pass the meridian of life, growth ceases; there is much less physical activity and therefore much less need of starchy, fatty and albuminous elements. Therefore, as we advance in years these foods should be reduced in amount and
replaced by the dissolving and eliminating fruits and vegetables, but conventional habits and the doctor's advice usually favor the opposite course.

"You are growing older," says the doctor; "you must have plenty of strengthening foods—meats, eggs, fish, fowl—and you need some stimulants. Coffee or tea is all right and an occasional glass of beer or of "Duffy's Old Malt" won't hurt you, either."

Frequently a patient tells us, "All the young people in our house are now living on the natural diet, but you know father and mother are growing old and they must have their soup and meat, their coffee and beer; in order to keep up their strength."

Reverse the prevalent ideas on hygienic living and you are just about right; so in this regard the very opposite policy should be adopted. The older we grow, the less we need of the heavy, clogging foods and the more of the light and purifying.

The majority of people eat too much anyway. Habitual stuffing practiced through many generations has made it second nature. Many consume the best part of their available vital force in endeavoring to digest and eliminate superfluous quantities of food and drink. Every ounce of food in excess of actual need wastes vital force.

A Roman proverb said: "Plenus venter non studet libenter"—a full stomach does not like to study.

Vital energy required to remove useless ballast cannot be transformed into physical or mental energy. Vital force is a primary force. It cannot be eaten. It comes from the source of all life and is independent of the physical body just as electricity is independent of the bulb which it fills with light. Food can only furnish fuel material for the flame of life and keep the human organism in such condition that vital force can manifest itself in it and through it. If food and drink could give life they should prolong it indefinitively; in that case the glutton and drunkard would live the longest, but common experience teaches us that the man temperate in all things best preserves his physical and mental vigor and lives the longest.

The beauty about all this is that nature cure philosophy does not confine itself to visionary theorizing, but that it "delivers the goods". If we can take all sorts of chronic incurable diseases and within four or five months or a year's time work a wonderful transformation and actually cure the majority of such patients and give them a new lease on life, why should it be impossible to prolong life to its natural limit and to retain to the last, unimpaired, our faculties, capacities and powers of body, mind and soul?

How much greater would be the possibilities for health and longevity if human beings were brought into life and treated in the natural way from the beginning; that is, from the time
of mating and conception through the prenatal and postnatal periods and on through youth and maturity. Within a few generations the offspring of such Natural heredity would live the full allotted time of a hundred and fifty years in perfect health, strength and beauty, thoroughly efficient in the business of life, a true aristocracy not of vitiated, degenerated blue blood, but of pure red blood of perfect buoyant health.

Many of our young people are now beginning to carry out this great plan for the creation of a better, healthier and more beautiful humanity. They are seeking partners among those who have been educated and trained in the ways of natural living. If the offspring of such naturally mated couples do likewise and select their partners in turn from among those who are the product of natural heredity, what a different humanity will inhabit this earth within a few generations.

This is not vain dreaming. It is marvelous how the youth of this country have taken hold of these new ideas; how many are adopting the new life in harmony with Natural Therapeutic philosophy, physical culture teachings and other Systems of natural living and healing. Quite frequently young couples come to me, saying, "Doctor; we want to get married; but before we do, give us a thorough examination and, if necessary, we intend to take a course of treatment in order to put our bodies in right condition for the great responsibilities of matrimony and procreation."

What wisdom—what a glorious promise of a better; healthier and happier humanity!

**How to Grow Younger**

Keep in the light—cultivate the air and light bath—nothing sweet or beautiful grows or ripens in the darkness.

Avoid fear in all its forms of expression; it is responsible for the greater part of human suffering. The only thing to fear is fear.

Don't live to eat but eat to live. The cook is the chief executioner of King Death.

In the morning do not say, "I am another day older and so much nearer the end"—say "I feel one day younger."

How can we grow old with all eternity before us! The wise men tell us that in the higher life the good ones always appear in the vigor and beauty of mature manhood and womanhood.

What difference makes it if this old suit of ours grows a little shabbier? We shall soon wear a new and better one.

Be as a child, live simply and naturally, steer clear of too much money and too much worry.

Cultivate the spirit of content; nothing ages the face and furrows the brow so quickly as nagging discontent, suspicion
and jealousy.

Before going to sleep, throw off all the cares and anxieties of the day and attune your physical, mental and psychical vibrations to harmonies of rest and peace and love.
PART V

SECTION XLII

FIRST AID IN ACCIDENTS

A person in possession of a clean, healthy, supple body as a result of natural living and treatment, is not nearly as likely to suffer injury from accidents or to develop chronic after effects resulting from them as one whose body has lost its natural elasticity, keenness of sensory organs and recuperative powers through unnatural habits of living and the resulting Pathogenic conditions. This is well known to physical examiners for accident insurance concerns. When a body is in a pathogenic condition, a slight scratch may be sufficient to cause serious blood poisoning or a bruise or fracture may result in necrosis or tumor formation.

Natural methods of treatment are as efficient in giving first aid as in the treatment of acute and chronic diseases, though it may be necessary in serious cases to procure without delay the aid of a surgeon or trained osteopath, chiropractor or neurotherapist in order to examine for internal injury or to correct sprains, dislocations, fractures or other mechanical lesions. However, any layperson possessed of ordinary intelligence and common sense can apply the first aid methods herein described.

In many instances, natural treatment applied in time will greatly ameliorate the suffering and establish the best possible conditions for perfect recovery. The old time drug treatment which was held to be indispensable in cases of accident is as useless and harmful under these conditions as in the treatment of acute and chronic diseases. Much experience in all kinds of emergencies has convinced me that this is true.

In case of an accident it is of primary importance not to become excited and thereby to lose presence of mind and self-control. It is only by remaining cool and relaxed that one can think clearly and decide quickly upon the best course to pursue.

In first aid as well as in acute diseases the quickest and best results are obtained by hydropathic and manipulative treatment. It is, therefore, necessary for the student of emergency work to thoroughly study the methods and applications described under those headings. In order to facilitate quick and ready reference I shall treat the various occasions for first aid in alphabetical order.

1. Alcoholism. Acute alcoholism may result in complete collapse and stupor. It has frequently happened that a person
found in an insensible condition in a public place is mistaken for a drunkard in a stupefied condition, and carted off to a police station, when in reality he is suffering from injury, - a stroke of apoplexy, sunstroke, heat prostration or from some other serious physical disorder. In order to prevent such mistakes, which might easily result in the death of the sufferer through lack of proper care, it is necessary to smell the breath, which, in cases of alcoholism, will immediately tell the story.

a) The best treatment for alcoholic stupor consists in brisk cold rubs, followed by good massage and neurotherapy treatment, calculated to stimulate and to revive the activity of the brain and nervous system. An enema of a warm, normal salt solution is also very beneficial. When the patient revives, half a cup of black coffee with lemon juice will act as a mild heart stimulant.

b) Delirium Tremens is a form of acute mania brought about through temporary paralysis of the brain centers which are the seat of reason, Will power and self control. The lower animal emotions are running amuck and in many such cases various forms and symptoms of abnormal psychism prevail. The horrible experiences and visions of people in this condition are not always delusions and hallucinations but frequently are the result of clairvoyance and clairaudience on the lowest spiritual or astral planes, the purgatories and hells of the theologians.

The various phases of abnormal psychism are fully treated in Volume IV, Eugenics. This abnormal functioning of the sensory organs of the spiritual body is brought about through the temporary paralysis of the sensory organs of the physical body;

In order to prevent complete collapse it may be necessary to give at increasing intervals and in decreasing doses, alcoholic liquor, coffee, tea or other light stimulants to revive and strengthen the animal magnetism of the physical body. Tincture of passiflora administered every two or three hours in from ten to twenty drop doses is a good non-poisonous vegetable tonic. Meat broth, Tartar sandwich and other flesh foods may be given until the patient has recovered from the abnormal psychic condition.

The hydropathic treatment consists of cold rubs and cold douches, wet packs and cooling sitz baths. Massage and neurotherapy treatment is of great importance in such cases, not only for its mechanical but also for its electromagnetic effects.

Epsom salt or sea salt rubs also have a positive magnetic effect upon the system. Hot bathing, bromides and other "sedative" measures only aggravate the condition because they have a weakening, benumbing effect. Those who apply such sedative remedies forget that delirium tremens and other maniacal conditions are the result of weakness, exhaustion, and of a benumbed and semi-paralyzed condition of the brain.
and nervous system, and that, therefore, tonic, energizing treatment is required instead of benumbing, sedative remedies and applications.

When the patient has recovered from the effects of acute alcoholism he should undergo thorough systematic natural treatment in order to eradicate completely the craving for alcoholic stimulants. We have treated and permanently cured many victims of the drink habit who had undergone all sorts or drink cures without permanent results. As drug cures for the drink habit work on the principle of "poison kills poison". It is Beelzebub against the devil. While drugs may temporarily kill the craving for alcoholic liquors, the results thus obtained are not permanent. As the effects of the drug treatment pass off, the old craving returns and the drugs themselves have a weakening and deteriorating effect upon the system. Such Cures do not influence the moral nature.

Natural treatment with its "back to Nature" life, its pure food diet, and Its educational influences through daily lectures and suggestive treatment, arouses higher ideals, strengthens will power and self control, and thus overcomes in a natural way the desire for alcoholic stimulants as well as habit creating drugs. It accomplishes this, not by the introduction of other poisons but by the purification of the organism and by the presentation of higher and purer ideals. One who, after such physical, mental and moral regeneration, has tasted the sweetness of the natural life will never again crave the gross deceptive gratification afforded by indulgence in alcoholic liquors and habit-forming drugs.

Strict adherence to a natural regimen for three or four months will take away all desire for alcoholic or drug stimulation. Patients have confessed to me that they did not backslide on account of an irresistible craving, but through careless surrender to temptation. Self control must be strengthened by educating the moral nature. Antidotes. See Poisoning, no 26.

2. Apoplexy. Apoplectic stroke and the resulting paralysis are caused by the breaking of one or more blood vessels in the brain. If the hemorrhage occurs in the right brain hemisphere, the left side of the body will be affected by paralysis on account of the crossing of the nerve tracts in the medulla and spinal cord. If the hemorrhage occurs in the left brain half, the right side will be affected. The extent of the paralysis depends upon the amount, of damage done to the brain centers in the area affected by the hemorrhage. The breathing is labored and stertorous, the face is flushed and purple in color, the features are twisted and drawn to one side, the pupils of the eyes are usually dilated.

a) The head and shoulders should be slightly raised. Quick, cold salt rubs followed by stimulating manipulative treatment will draw the blood away from the brain into the surface and extremities. A lay-person can give the extremities and fleshy parts of the body a good, thorough kneading, rubbing and
stroking, but a trained masseur or neurotherapist should be procured as quickly as possible to complete the treatment.

b) Wet packs applied to the body and, the extremities will draw the blood away from the congested brain area. A warm normal salt enema (Sec. XVIII, No.4) will help to establish normal circulation. A hot mustard bath applied to the feet or, better still magnetic treatment (p.397) will divert the blood into the lower extremities.

c) After consciousness has been restored, the patient must undergo thorough, systematic natural treatment in order to eliminate from the system the, pathogenic materials which have caused high blood pressure and the hardening and occlusion of the blood vessels in the brain and all through the body, and which brought about the hemorrhage and resulting paralysis. No alcoholic or drug stimulants should be given because they increase blood pressure to the brain.

d) In cases of concussion of the brain, apoplectic stroke, or of hemorrhages from the lungs or stomach, the patient must not be transported in a vehicle because the jolting might aggravate the condition. The sufferer must be carefully carried on a stretcher.

Of the many patients we have treated after a first apoplectic stroke, not one, as far as I can remember, has suffered from a second attack, provided of course there has been careful adherence to natural ways of living.

3. Artificial Respiration In many kinds of accidents, such as drowning, strangulation, asphyxiation by poisonous gases, and in serious cases of fainting and stupor, it may be necessary to resort to artificial respiration in order to restore normal breathing. There are several good methods for this purpose.

a) Quickly remove the clothing from the upper part of the body; lay the patient prone upon his stomach, place a small wad made of clothing or any other material at hand, under his forehead in order to elevate nose and mouth sufficiently to allow free breathing.

The operator knees athwart the legs of the sufferer and places his spread hands on both sides of the small of the back and then exerts gentle but steady pressure, thus compressing
The lower ribs and chest; he then gradually releases the pressure, allowing the lungs to fill with air. This alternating compression and relaxation of the chest must proceed at the same rate as the normal tempo of breathing, which is about fifteen breaths to the minute in adult life and a little more than this in childhood. With adults, therefore each complete movement in artificial respiration should consume about four seconds including expiration and inspiration, while in children it should consume about three seconds.

b) The same method may be applied while the patient is lying on his back. Make a roll of clothing and shove it under the small of the back so that the head lies lower than the chest. Then kneel astride of the hips, place both hands, fingers spread as far as possible, on the lower ribs below the nipples of the breast and count slowly one, two, three, four; while counting one and two, compress the lower chest gently but firmly and relax the pressure while counting three and four. Continue this alternating compression and relaxation until normal breathing commences (provided life is not extinct). A sudden trembling and heaving of the chest and flushing of the face will indicate when natural breathing commences. While compressing the chest, the operator should at the same time apply strong vibration. This is accomplished by vibrating the hands loosely and vigorously from the wrist joint. The slow, regular counting corresponds to the tempo of regular normal breathing.

c) (Fig. 25a, b, p.385) Another, more commonly applied method of artificial respiration, is the following: The patient lies upon his back; a small roll of clothing or other soft material is placed under the small of the back in order to raise the chest and to facilitate expiration. Inspiration is induced by raising the chest through bringing the arms above and back of the head; expiration is produced by returning the arms downward and in an outward, circular movement to the sides of the body, doubling them at the elbows and pressing the forearms on to the chest (Fig. 25 b). Compression must be followed by relaxation. This alternating compressing and releasing or raising of the chest should also be continued at the rate of fifteen complete movements to the minute for adults and twenty for children, or it may be regulated by counting as in the operation previously described.
The first method (a) is to be favored because it prevents the falling back of the tongue into the throat and because it facilitates the escape of water, mucus or froth from the mouth. This is especially important in cases of drowning when the lungs are more or less filled with water.

**d)** (Fig. 26) The best method for facilitating the escape of water from stomach and lungs is the following: Lay the victim prone upon his face, stand athwart his body, place your hands under his stomach and raise him at short intervals, thus partially doubling the body upon itself. This compresses the internal organs and facilitates the discharge of fluids through the mouth.

4. **Asphyxiation or suffocation** is a condition of unconsciousness and insensibility resulting from suspended respiration. It is caused by a deficiency of oxygen in the system and an excess of carbon dioxide. This may be
produced by strangulation, as in hanging, by smothering or internal obstruction, as in choking, drowning, or by the inhalation of smoke or poisonous gases.

The treatment consists, first in artificial respiration described previously; and, secondly, in restoring the circulation of the blood and nerve currents. This is best accomplished through hydropathic and manipulative treatment described under acute alcoholism. The revival of an asphyxiated person may require long continued effort. Cases are known where by three or four hours of persistent effort, people have been revived after hanging or other forms of strangulation or suffocation.

a) The victims of carbon dioxide asphyxiation die because this gas is heavier than oxygen and therefore does not allow this life-sustaining element to enter into the lungs and tissues of the body. A pulmotor may help to force the oxygen into the lungs and to expel the CO2.

b) While rescuing a person from a room filled with smoke or poisonous gases, a wet handkerchief or other piece of wet cloth should be tied over the mouth and nostrils. Breathing should be restrained as much as possible. Care must be taken not to strike a match as it may explode the hydrogen gas. The windows should be opened or broken at once. This will enable the life-saver to take an occasional breath of fresh air while trying to find and to remove the victim of asphyxiation to the outer air.

5. Bandages. When bandaging wounds, fractures or other bodily injuries, care must be taken not to apply the bandage too tightly. This might seriously interfere with the circulation, especially if swelling develops in the injured parts.

a) Triangular Bandage. One of the most useful bandages in accidents is the triangular bandage. This may be prepared from any square piece of cloth by folding it diagonally in the shape of a triangle. Figures 27, 28 illustrate the application of the triangular bandage to a broken forearm Figure 29 illustrates other uses of this bandage. Fold a square piece of
muslin or other material into triangular form and place against the body underneath the injured arm. Point A is drawn over the uninjured shoulder; point B is brought up over the injured arm and shoulder and knotted or tied to point A behind the neck.

The projecting flap D is folded over the elbow and fastened with a safety pin. This supports the arm in a comfortable position.

The inner surface of the hand must be turned inward and the thumb upward. Fig. 29 shows the application of the triangular bandage to injured hands and feet.

b) Figure Eight Bandage. Fig. 30 illustrates the Figure Eight bandage applied to hand and foot. A long bandage, three or four inches wide is applied with its center to the injured part. The ends are then drawn crosswise around the wrist or ankle and knotted or pinned with safety pins.

c) Roller Bandage Figures 31, 32 illustrate the application of the roller bandage. This bandage may be from a few feet to a few yards in length and of any width best suited for its purpose. The bandage is first rolled up either in a single roll or in two rolls from each end (Figs. 31, 32). The single roll bandage is rolled up from one end and applied by unrolling from one end. It should be applied by winding smoothly and evenly around the injured part, but this is possible only when the part is of even thickness. If the injured part is of uneven thickness, as in the case of an arm from the wrist upward or a leg from the ankle upward, the bandage in order to be applied smoothly and firmly must be reversed upon itself. This is done by placing the thumb upon the bandage where it is to be folded back upon itself, as illustrated in Fig. 31.
d) **Double Roll Bandage.** The double roll bandage is applied with its center over the injured part; both ends cross in the back and are then wrapped around the part in opposite directions. (Fig. 32, no 5c))

e) **The T Bandage** has been described under Sec. XV, No.18.

f) **Head Bandage.** Bandages suitable for injuries to the head or for holding in place compresses to the head are applied as shown in Fig. 33. One bandage is drawn over the head to point c and fastened under the chin at a. The other bandage, no 2, is drawn over the back of the head and the base of the skull, and fastened over the forehead.

g) **When the chin or lower jaw is injured,** bandage (a), which supports the chin, is knotted on the top of the head. Bandage (b) is applied over the chin and knotted at the back of the neck. (Sec Fig. 34.)

6. **Bites** by snakes, dogs, cats or by persons in an enraged or maniacal condition, should be sucked out immediately if they can be reached, by either the victim himself or by a friend. The mouth of the one who performs this operation must not contain wounds or abrasions and should be thoroughly cleansed with water after each withdrawal of blood. The wound, if necessary, should be widened by an incision and
cleansed with dilute lemon juice. Immediately after this there should be applied a wet bandage or wet pack.

The elimination of any possible infection must be promoted through fasting or raw food diet, manipulative treatment and all other natural methods described in this volume. Of special importance in this respect is the bed sweat bath followed by cold ablutions.

In cases of snake bites, never administer whiskey or other alcoholic liquors, nor stimulating drugs. This is not only absolutely useless but decidedly harmful and dangerous. According to reliable statistics, less than eight per cent of people bitten by rattlesnakes or other poisonous reptiles die from the effects of the venom even though no whiskey is administered. On the other hand, many cases undoubtedly end fatally on account of the whiskey treatment. Excessive stimulation is always followed by corresponding depression and frequently by complete collapse. This is most likely to occur when large quantities of the fiery liquor are poured into people who are not accustomed to its effects.

7. Bruises, Bumps and Contusions. These are treated best by the application of wet packs or clay packs. See Sections XV and XVI.

While bruises and bumps do not bleed externally, the torn blood vessels may bleed internally and cause red or black discolorations. Such internal hemorrhage can be best arrested by firm pressure applied around the affected area; that is, by pressing some hollow object such as a spoon or a cup firmly around the bruise. The cooling packs or compresses will allay any tendency to inflammation or suppuration. Raw beefsteak applied to bruises acts in a manner similar to wet packs.

8. Burns and Scalds. When the clothing is afire one should not run about excitedly, as this will only fan the flames to greater intensity. The best way to extinguish the fire is to throw oneself prone upon the ground and smother the flames by rolling. Rugs, blankets, pieces of clothing or any other material within reach may be used by the victim of the accident or by those who are trying to aid him, to smother and to extinguish the flames. Rolling on the floor prevents also the inhalation of the flames or smoke and the burning of face and hair.

While removing the clothing from a body injured by burns or severe scalds, do not try to tear it off by force, but cut around the places where the clothing adheres to the flesh.

The best treatment for burns and scalds consists in applying a mixture made of ordinary baking soda (bicarbonate of soda) and ordinary boiled oil (linseed oil) or olive oil. This simple remedy which can be procured in almost any household, is of wonderful efficacy in the healing of burns and scalds. It allays pain even in severe and extensive sores and prevents the formation of blisters while greatly facilitating the healing
process. The alkaline sodium neutralizes the poisonous acids which form in the sores and the oil keeps the flesh in a softened condition and prevents caking and cracking.

In cases of very extensive burns or scalds, immersion under water of body temperature or slightly below, has been found very beneficial. In such cases the patient may remain suspended under water in a hammock for days or weeks at a time until the sores are healed sufficiently to allow exposure to the air.

Burning of the eyes and face by strong acids, fresh slaked lime, etc., is best treated by the immediate application of the olive oil and baking soda mixture.

For the treatment of shock due to scalds or burns, see "Shock".

**Carrying** an unconscious person (see Transporting an Injured Person, p.417).

**9. Choking.** Infants and children frequently choke as the result of swallowing small playthings or other foreign objects. Adults may choke from getting fish bones stuck in their throats or trying to swallow large pieces of meat.

If the patient is a child, place him face downward over your lap, and slap him vigorously between the shoulders. If this does not remove the obstruction, then compress the nostrils, which forces him to open the mouth and throat widely, introduce the fingers of the other hand quickly into the throat and try to grasp the obstructing object. If this is not possible, tickle the palate with a feather, a finger, or with a handkerchief rolled to a point. The tickling will cause coughing or hawking which may dislodge the obstruction.

An adult may throw himself over a chair or table, the head hanging downward, while another slaps him vigorously between the shoulders or, if necessary, performs the operations described in the previous paragraph.

**10. Convulsions.** These are due either to congestion of the blood in the brain, to abnormal pressure of gas on the heart, or to excessive irritation of the brain or nervous system by toxic substances.

The treatment must be adapted to the individual condition. Most of these have been described in Vol. V under Epilepsy, Uremia poisoning and other forms of diseases.

a) For first aid the patient should be placed in a recumbent position with the head slightly raised. Alternating hot and cold fomentations are most effective for drawing the blood or irritating toxins from the affected area into the surface. The patient should sip hot water mixed with a little lemon juice. An enema of normal salt solution and of blood temperature should be administered as soon as possible. Wet packs applied
to the neck, trunk or extremities will also draw the blood into the surface and thus relieve inner congestion and promote elimination of toxic substances. A full hot bath of body temperature of from ten to fifteen minutes duration may give quick results in serious attacks. This should be followed by a brisk cold saltwater rub.

In convulsions of infants the body first becomes cold and rigid, then the skin breaks into a clammy perspiration, the pulse is weak and rapid. This is followed by convulsive movements and later by a semi-comatose condition which usually passes into a natural sleep.

After the first aid measures herein described have given temporary relief the underlying causes must be overcome by natural methods of treatment

b) Uremia convulsions frequently occur in the course of Bright's disease and of diseases which cause prolonged retention of the urine in the bladder In such cases it is imperative to increase the activity of the skin in order to compensate for lessened elimination through kidneys and bladder The best way to accomplish this is to apply the bed sweat bath described under Sec. XIV, No. 5, p.143.

Sufficient hot water bags, bottles, or heated bricks must be placed outside of the whole body pack and under the outer blanket covering so as to produce free perspiration. The patient remains in the pack from fifteen to thirty minutes, as long as he can endure it.

After the removal of the pack he is quickly rubbed down with cold water, either in a bathtub, spray room or in bed. He is then covered well with blankets in order to induce free "after perspiration". This procedure is repeated as often as the patient can endure it and react to it properly. After the pack has been applied, the patient should drink freely of hot lemonade made with brown sugar or honey. This will promote free perspiration.

Expert massage and neurotherapy treatment should be given to stimulate the circulation, to promote the elimination of morbid matter and to correct spinal or other mechanical lesions. Juniper berry tea (Sec. XIX, No. 5) will stimulate the activity of the kidneys. Fasting is imperative. It must be extended for days or weeks, according to the nature of the disease back of the convulsions. In cases of serious ailments such as Bright's disease, inflammation of the bladder, subacute and chronic prostatitis, the fasting must be followed by raw food diet for weeks or months at a time.

Hot, normal salt enemas should be given to cleanse the lower intestines and to stimulate the vital activities.

For treatment of Epileptic convulsions see No. 14, p.398, this Section.
11. Cuts and Wounds. Small cuts or wounds should be thoroughly cleansed with warm or cold water and then treated with dilute lemon juice. Air and light are the best of all healers. It is injurious to close cuts with adhesive plaster, because it prevents elimination and shuts off air and light. However, in case of large wounds, the edges may be held together with narrow strips of adhesive tape just sufficient to keep the lips together for healing and to allow drainage. When the bleeding has stopped, the wound should be left uncovered if this can be done without exposing it to the pollution of impurities; or, the covering should consist of just enough porous gauze to protect it.

If the wound should prove painful or become inflamed, frequent bathing in cold water or allowing a stream of cold water to run over it, is the best remedy. If the wound is large enough to cause serious or dangerous hemorrhage, appropriate treatment must be applied. For this see "Hemorrhages", No. 18 (a), page 402.

Delirium Tremens. (See Alcoholism, p.379.)

12. Disease, Sudden Onset of. The simplicity of the natural treatment enables us to apply the most efficient treatment at the sudden onset of any disease whatever. While the medical man has to wait for days or sometimes for weeks before he can find out what the exact nature of the trouble is and apply his specific remedy, the natural therapist gives the most effective treatment from the first manifestation of symptoms. In that way he may be able to abort or to avert many serious diseases which might end fatally if neglected for a few days.

At the first appearance of great weakness, of aches and pains in any part of the body, of increased temperature and quickening pulse rate, a normal salt enema (Sec. XVIII, No. 4, p.165,) of body temperature should be administered in order to thoroughly cleanse the lower intestine. This should be followed by a full sheet pack (Sec. XV. No. 7) or by a trunk pack or, if reaction is unsatisfactory, by a full sheet bed sweat bath (Sec. XIV, No. 5, p.143). (See also description in Uremic Poisoning, No. 10. (b) 4 p. 394.)

Fasting must be enforced from the appearance of the first symptoms of malaise or acute inflammatory activity.

If there are signs of poisoning or of severe inflammation of, the stomach and intestines, vomiting should be induced immediately by means of drinking copious quantities of lukewarm water, either pure or mixed with salt or mustard. If vomiting cannot be induced in this way, tickle the throat with a feather or piece of cloth drawn over a sliver of wood. After thus thoroughly cleansing the stomach, allow the patient to drink freely of water mixed with the juice of acid fruits.

Neurotherapy treatment should be given at once to promote heat radiation, elimination of morbid matter, and to correct mechanical lesions.
A few days of such natural treatment will suffice in most cases to restore the system to normal condition. If an acute disease should develop, it will run a much milder end safer course after prompt natural treatment, and the results obtained will be infinitely better than under the old time drug treatment.

Carefully observe the following warnings, though you may find contradictory advice in books on naturopathic and physical and natural culture treatment: In acute conditions never apply hot water applications nor the ice pack; neither give cold water enemas. They are very dangerous, as they may suppress the inflammatory process and bring about fatal collapse. In cases of serious shock or collapse where the vitality is too low to react to cold applications, alternating hot and cold fomentations are in order, and the wet packs may be wrung out of hot water instead of cold water.

If the hands and feet remain cold and bloodless the best remedy for bringing the blood to the extremities is good magnetic massage. After the manipulative treatment, firmly hold the hands of the patient or grasp the feet around the ankles and will the blood to flow into the extremities. The magnetic treatment must be continued until the hands or feet warm up.

The hot bath or hot water bag treatment produces warmth temporarily but is followed, in accordance with the law of action and reaction by cold reaction; therefore the anemic condition of the extremities is only made worse by such hot applications.

**Drowning** (See No. 3, pg 383)

13. **Ears, Foreign bodies in**, locate the foreign body by using an ear speculum and head mirror. Turn the patient on the affected side and use a syringe from below, to straighten the canal, pull the outer ear up and back. In some cases forceps made of fine wire may be necessary. Living insects in the outer canal may be killed by the injection of alcohol or oil and then removed by syringing or by the wire loop. In cases of peas or beans, do not use water; it will make them swell. Use a wire loop or attach a strip of adhesive plaster to the foreign body and pull it out that way.

Foreign bodies in the nose may be removed in a similar manner.

14. **Epileptic Convulsions**. Nothing must be done to check or suppress the convulsion; this would be very injurious. All that can be done during an attack is to place the patient in a comfortable position and to elevate the head slightly. A neurotherapist should give firm inhibitory treatment over the upper cervical vertebrae and at the base of the skull. Immediately apply rectal dilatation.

If the fit occurs in the house, the patient should be exposed to a draft of fresh air. Push the lower jaw forward so that the
lower row of teeth projects over the upper. This will keep the windpipe open and prevent choking and suffocation. Push a piece of wood padded with a cloth, a cork or a rolled handkerchief between the teeth in order to prevent biting of the tongue. The opening of the clinched hands is useless.

After the attack the patient should rest until its effects have worn off. The treatment for the cure of the disease must be administered between the attacks. Two-thirds of such cases that have come under our treatment made permanent recoveries.

**Exhaustion.** (See Heat Exhaustion, p.401.)

15. **Eye Injuries.** (a) Black eye. Caused by external injury, blows, etc. Natural treatment: Cold applications applied immediately will prevent discoloration and will alleviate inflammation.

Burns. See treatment for burns, No. 8, p.391.

b) Foreign bodies in the eyes, such as cinders, bits of sand, etc. These are usually found imbedded in the cornea or in the lid. Pull the lid outward and bend it backward over a toothpick, a match or other bit of wood, thus exposing the inner surface. Then remove the obstacle with a bit of cotton if it is imbedded in the lid; or if necessary with a toothpick or sharp instrument if it is located in the cornea. Treat inflammation with cold compresses and cold eye baths.

c) Perforating Wounds. Perforating wounds of the eyes should be treated with cold compresses and cold eye bath. The patient must remain absolutely quiet and not expose the eyes to any strain whatever. If the sight is lost and symptoms of sympathetic inflammation appear in either eye, removal of the affected eye may become necessary, but this will seldom be the case if the cold compresses and the potato compress and cold ablutions are applied faithfully from the start (Sec. XV, Nos. 1, 4, pp. 147, 148). In any case of injury do not use vaseline, atropine or antiseptics.

16. **Fainting—Insensibility.** Find out first whether the unconscious one is alive and breathing. Hold a mirror, piece of glass, bright piece of metal or a feather before the mouth and nose. If the patient is still breathing, the bright surface will be dimmed by the breath, or the feather will move.

a) The following is another test for determining whether life is extinct. Raise the eyelid and touch the white of the eye. If life is not extinct, the eyelid will twitch. Observe the odor of the breath. It will indicate such poisons as alcohol, chloroform, ether, etc. If the tongue has been bitten it indicates epilepsy. If the eyes are sensitive to touch and light, there is no brain injury. Unequal contraction of the pupils indicates brain trouble. Pupils contracted to pin points indicate opium poisoning. Slow, weak breathing indicates collapse or shock. Snoring or stertorous breathing and slow, weak pulse
indicates brain trouble. Rapid pulse points to sunstroke. A hot skin and rapid pulse indicate sunstroke or high fever. Cold skin and weak pulse may be the result of fainting, freezing, or of acute alcoholism. High fever should be treated as described under treatment of acute diseases (Sec. VII {pg. 76, 77).

b) If the patient is still breathing, place him in a comfortable position, the head somewhat lower than the rest of the body. Open or cut the clothing wherever it constricts the body, and expose the patient to a draft of fresh air, if in the open, fan the air, over his face.

c) In order to stimulate heart action, apply, alternate hot and cold compresses to the chest; sprinkle or dash cold water over the face and neck; also apply alternate hot and cold fomentations to the, spine. Massage and apply passive movements to the extremities. If the, breathing is very slow and faint, apply artificial respiration (No 3. page 383). Dash cold water on the neck and on the soles of the feet. Give cold salt water rubs, all over the body. Administer a, warm normal salt enema (Sec. XVIII, No. 4, p.165,). Do not try to administer water or stimulants while the patient is unconscious; it would only choke him.

d) When he revives do not give alcoholic liquors or other poisonous stimulants. The reaction might prove fatal. Give sips of fresh water mixed with acid fruit juices, or, black coffee or tea in small quantities; repeat until full consciousness has been restored.

e) Try to find out what caused the unconscious condition. It may be the result of any one of the following causes: Fainting; collapse, shock, asphyxiation by gas; drowning or other means, acute alcoholism, opium, chloroform, ether or other drugs, sunstroke, apoplexy, epilepsy, convulsions, injury to the brain by concussion or fractured skull, or it may be caused by certain diseases of the heart stomach or kidneys. Treat accordingly.

17. Fractures. In case of fracture, a physician or Surgeon, must be secured without delay. In the meantime excessive bleeding may be stopped as described under "Hemorrhages" (p.402). Swelling may be reduced by wet packs and cold ablutions.

18. Freezing. Frozen limbs, ears, nose or other fleshy parts, of the, body should be, rubbed vigorously with ice water, or snow. Great care, however, must be taken not to break the frozen parts; they are brittle and may break easily.

If a person has become unconscious through freezing, he must be taken into a cold room and treated with cold rubs by means of ice water or snow, until the circulation in the various parts is restored. As before stated, great Care must be taken not to break the frozen parts.

If breathing and heart action are very low or imperceptible,
artificial breathing, with due precautions, must be at once resorted to. The individual condition must determine the best method to be employed. When normal breathing commences, place the patient in a cold bed and heat the room very gradually.

When the body becomes warm, rub with warm flannels, but the frozen parts must still be treated with cold applications and snow rubs.

Warm the body from within by giving hot lemonade with brown, unrefined sugar or honey. Black coffee with lemon Juice will stimulate heart action and circulation.

To drink alcoholic liquor in order to keep warm is extremely dangerous. The benumbing after effects of this and other strong stimulants will induce numbness and sleep when wakefulness is necessary to resist the freezing.

19. Heat Exhaustion is usually the result of injudicious diet in summer, excessive clothing, and of working in close, hot, ily ventilated rooms. The principal symptoms are faintness or syncope; a cold and damp skin and a rapid and feeble pulse. When death results it is due to heart failure; but most cases recover. It is not as often fatal is sunstroke.

a) The patient should be removed to a cool place. Hot lemonade will stimulate the heart action; a brisk, cold rub and wet packs, if necessary reinforced by hot water bottles will restore the activity of the skin. (See Bedsweat Bath, Sec. XIV, No. 5, p.143)

b) Both in sunstroke and heat prostration the head should be frequently laved with cold water. If the body temperature is subnormal and death seems imminent, the legs should be wrapped in woolen blankets saturated with hot water. Care must be taken not to scald the flesh. Around the wet blanket wrap several layers of dry sheeting or a dry blanket in order to retain the heat. The patient should take at intervals small quantities of hot lemonade.

Heat Prostration (See Heat Exhaustion, p.401.)

20. Hemorrhages. (a) Hemorrhages from the mouth. When the blood is of dark color and looks as if it were mixed with coffee grounds or food materials it comes from the stomach and the hemorrhage is caused by cancer. If the blood is mixed with food materials but looks bright red, the hemorrhage is caused by ulcers of the stomach. If the hemorrhage is from the stomach, the patient should be placed in a recumbent position. A trunk pack will draw the blood away from the stomach and relieve congestion. The patient should sip at frequent intervals small quantities of cold water mixed with lemon juice, and should be allowed to rest.

b) Hemorrhage from the Lungs. When the blood is bright red and foamy and free from food materials, it comes from the
lungs and is caused by breakdown of the lung tissues. It is not necessarily directly fatal. Under natural treatment of lung diseases, hemorrhage frequently occurs during the crisis periods and is then a form of elimination. In many cases, recovery from tuberculosis has been preceded by copious hemorrhages. The patient should be kept in bed in order to give the disrupted tissue a chance to heal. The treatment must be directed to the underlying disease.

e) Hemorrhages from Cuts and Wounds. If the blood is bright red and comes in spurts, it is an indication that some important artery has been severed and a ligature should be applied without delay above the wound. If on the trunk of the body, pressure should be made above the wound, between it and the heart. Any solid object, a piece of wood, rock or anything convenient, held in position firmly by a bandage or belt will serve the purpose. (Figs. 35, 36.)

d) If the blood is dark in color and flows smoothly, then some vein has been opened and the ligature should be applied just below the wound. (Fig. 37) Any strap, rope or handkerchief may be used for this purpose, but a rubber hose, if it can be procured, is best suited on account of its elasticity. The ligature may be applied more tightly by inserting a stick, pipe or similar object below the knot and twisting it. (Fig. 35.)

Do not try to remove any clots of blood; they are Nature's provision for stopping the hemorrhage. Hemorrhages from large arteries may be stopped temporarily by compressing the blood vessel with the fingers. In order to do this, one must know where to find the arteries.

e) For an injury on the side of the upper part of the head, the temporal artery, must be Compressed with the thumb. This artery is located about three-quarters of an inch in front of the opening of the ear underneath the temporal bone. (Fig. 38)
If the injury is in the back of the head, the occipital artery must be compressed with the thumb. It is located about an inch from the center of the back of the ear. (Fig. 39) The facial arteries can be compressed by exerting strong pressure at a point one inch in front of the angle of the lower jaw. (Fig. 40.) The arteries pass over the jaw at these points. They should be pressed at the same time on both sides.

The common carotid artery can be reached at a point one and a half inches above the joint between the breastbone and the collar bone. Pressure may be exerted inward and backward. (Fig. 41.)

The subclavian artery can be reached at a point behind the middle of the clavicle or collar bone where the hump of this bone is felt. First lower and draw the shoulder forward, then press downward and backward with the thumbs or with the fingertips of both hands. The pressure must be firm and persistent. (Fig. 42.)
The axillary artery can be compressed by first raising the arm, pressing it outward and backward, and then compressing the artery on the inner surface of the upper arm. (Fig. 43.)

The brachial artery passes along the inner border of the biceps muscle. First extend or raise the arm, then press outward and backward. (Fig. 44.)

The radial and ulnar arteries in the wrist may be compressed readily with the fingertips. (Fig. 45.)

The great femoral artery in the upper leg can be reached best in the groin just in front of and a little inside of the femur bone. Compress with the thumbs or by using as many fingers as are needed.

The popliteal artery can be reached by strong pressure in the central part of the ham, applied, while the patient is lying on his stomach, directly downward.

The wounded part should be raised as high as possible.

Cold water is very effective for stopping hemorrhages. If possible it should be allowed to run over the wound in a constant stream. This inhibits the circulation and favors the clotting of the blood. Care must be taken not to run the water directly on the wound as this might prevent the forming of clots. In order to accomplish this it may be well to place a cup or saucer or some other protecting object directly over the wound.
Only boiled or aseptic bandages should be applied to the wound. **Clay or mud must never be applied to open cuts or wounds.** Water mixed with lemon juice applied directly to the wound acts as a natural antiseptic and astringent, thus favoring the clotting.

**21. Hiccough or Hiccup.** This is a spasm of the diaphragm, caused by nervous irritation of some kind. It may be due to digestive disturbances or to irritation caused by systemic or drug poisons. In chronic form we find it frequently associated with mercurial, phosphorus, strychnine and other drug poisoning.

Ordinary hiccough requires little or no special attention. If it persists, one of the best remedies is to continuously sip and swallow water until one or two of the spasms have been missed; anything that will break the regularity of the spasm will stop it. Out of this fact grew the old custom of "frightening the hiccough" by a sudden motion or exclamation.

In its most serious forms, in cases of drug poisoning, we have always succeeded in alleviating and in most instances overcoming the spasms by the natural treatment. Certain neuropathic moves give excellent results.

**Insensibility.** See "Fainting" No. 16, p.399.

**22. Lightning Stroke.** If a stroke of lightning results in shock or collapse, treat as described under "Shock", p.414. If it results in burns, treat as described under "Burns and Scalds" (p.391).

**23. Mania.** A sudden maniacal outbreak, whether the result of an attack of insanity, of acute alcoholism or of great emotional excitation, is best treated by cold applications such as cold sprays, cold sitz bath, hip bath, quick submergence under cold water, or by cold wet packs.

Soothing manipulative and magnetic treatment is very effective.

It is wrong to submerge such patients for hours or days in warm or hot water. Such sedative treatment is as weakening as opiates and hypnotics and will only aggravate the underlying conditions which are always negative in character.

Such patients should have nothing but vitalizing, upbuilding treatment. Sedative drugs and long continued submersion in hot water will only aggravate the negative conditions and make the underlying ailments more chronic and incurable.

**24. Mental Disorders.** At the first appearance of symptoms of mental disorder; the patient should be placed in an institution for natural healing, where surroundings and treatment are favorable for early recovery.
25. Nose. (a) Foreign Bodies in. (See "Ears," p.397.)

b) Nosebleed. Sniff cool water mixed with lemon juice. This has an astringent effect upon the capillaries. Compress the nostrils temporarily, throw the head backward, and avoid vigorous blowing of the nose. Apply cold compresses to the neck at the base of the brain. Repose on a chair or couch, perfectly relaxed, in a sitting position and remain that way until the bleeding ceases. Refrain from any movement of the body. Have someone else catch the running blood in a basin or cloth. This is the best way to facilitate clotting of the blood.

If this is not sufficient to stop the bleeding or if it should grow worse have small plugs of cotton or muslin inserted tightly into the nostrils. However, it must be remembered that the bleeding may be a form of elimination. It often occurs as a form of healing crisis and should, therefore, not be interfered with unless necessary to avoid excessive weakening and collapse.

26. Poisoning. (a) The first thing to be attended to in any case of poisoning, whether or not the exact nature of it be known, is to empty the stomach. This may be accomplished by the swallowing of large quantities of warm water containing the appropriate antidote, and by tickling the palate with the finger or a feather, thus causing copious vomiting. The washing of the Stomach must be repeated several times. If mouth and throat are not burned, a rubber tube may be pushed down the throat into the stomach. By means of a funnel, warm water is poured through the hose until it overflows. The end of the hose outside is then suddenly, lowered below the level of the stomach and water siphoned out of it. This may be facilitated by having the patient assume a position prone upon the face during the draining of the stomach.

b) In emergency cases, mustard, common salt or powdered alum may be given as emetics in proportion of one teaspoonful of either to a glass of water. A lukewarm solution of soap in water is a simple and efficacious emetic. If no emetics are available, cold water should be taken freely and vomiting induced by tickling the throat.

After washing of the stomach, white of egg, milk, or sugared water should be given freely. They are soothing to the inflamed membranes and give the poisons something to work on. Blood warm enemas of normal salt solution (Sec. XVIII; No. 4. p.165) should be given repeatedly in order to eliminate the poison from the intestines. When the patient is strong enough bed sweat baths followed by cold ablutions will stimulate elimination through the skin.

c) In corrosive sublimate or other forms of mercurial poisoning, retained rectal enemas of milk or white of, egg beaten up in warm water will help to neutralize the destructive action of the metallic poison.
d) In all cases, fasting, with dilute fruit juices, should be enforced until the system has eliminated the poison and the injured membranes of the internal tracts have been repaired. Where the latter have been severely burned, fruit juices may cause burning pain unless they are very much diluted with water. In the mild dilute form, they will antidote the destructive effects of the poisons.

e) So called antidotes are effective only when administered immediately. The general rule is, against acid Poisons administer water mixed with baking soda or fresh Lime; other good antidotes are white of egg, rich milk or oil. These substances neutralize the acids.

f) Alkaline poisons must be antidoted with dilute vinegar, milk, white of egg and other albuminous substances which neutralize alkaline poisons as well as acid poisons by diluting them and giving them something to work on besides the tissues of the body.

g) Narcotic poisons like opium, morphine, belladonna, digitalis, poisonous mushrooms, ptomains, alcohol strychnine, etc., cause loss of consciousness, stertorous breathing, redness of the face, cramps and delirium. If the victim of poisoning is unconscious, artificial breathing must be resorted to (No. 3, p. 383), and the neck, chest and other parts of the body should be sprinkled with cold water. A brisk cold saltwater rub is very efficacious in reviving the vital activities. As a stimulant administer small doses of strong black coffee.

h) Arsenic, phosphorus, Paris green, vitriol, carbolic acid, hydrochloric acid and lye do not as a rule cause unconsciousness, but give rise to violent pains in the oesophagus, stomach and abdomen, followed by choking and vomiting. Some of these poisons burn the lips, mouth, oesophagus and stomach; such burns may be treated with a solution of baking soda or powdered chalk. The treatment otherwise is the same as given for alkaline and acid poisoning.

In cases of poisoning a physician should be called in as soon as possible.

i) Ptomain poisoning results from eating putrefying or decayed meats, fish, cheese, ice cream or other animal food products. The usual symptoms are collapse, subnormal temperature and pain in the digestive tract. Nature generally tries to remedy the trouble by vomiting and diarrhoea. Both these forms of natural elimination must be encouraged by the swallowing of warm water in large quantities and by warm saltwater enemas. (Sec. XVIII, No. 4, p.165.)

The treatment of ptomain poisoning is very much the same as that of other forms of poisoning. The stomach and intestines must be emptied and cleansed as thoroughly as possible by induced vomiting and by saltwater enemas, as
described in the previous paragraphs. After that, the patient should drink copious quantities of fresh water mixed with acid fruit juices. This is much better than the taking of poisonous antiseptics.

While the temperature is subnormal, the bed sweat bath by means of the trunk pack or full sheet pack will promote elimination through the skin. When the subnormal condition is followed by inflammation and fever, cold packs and ablutions are in order and the treatment in general is the same as that for acute inflammatory conditions described under Sec. VII; p.75.

j) External Poisons. Poisons which affect the human body from the outside include poison ivy, poison oak and poison sumac. Poisoning by insects, snakes and rabid animals has been treated under other headings.

Poison ivy and the other poisonous plants above named owe their toxic qualities to an odourless, transparent oil found on the leaves, bark and twigs, which is insoluble in water. These poisons are powerful irritants. Contact of the skin with these poison plants causes insufferable itching, swelling and vesicular eruptions. In severe cases there may be vomiting, colicky pains, fever and delirium. Parts of the body or the entire cutaneous surface may be covered with eruptions.

The U.S. Department of Agriculture recommends the application of a solution of acetate of lead to be applied to the itching skin. This, however, is a powerful suppressant. While the eruption disappears rapidly under this treatment, it drives the plant poison plus the drug poisons into the system, and wherever these concentrate the morbid soil is prepared for chronic disease.

The poison in its outward symptoms, as well as its internal chronic after effects, resembles very closely the psora or itch taint. Its suppression in the acute stages broadens the scurf rim and frequently produces typical itch spots in the iris.

The best homeopathic antidotes in acute and chronic cases are Rhus tox., psorinum or sulphur. The homeopathic rhustoxicana is a trituration of the ivy poison.

The Natural Treatment. First it must be remembered that the itchy, burning eruptions represent Nature's, effort to eliminate the poisons from the system and that therefore it should not be checked or suppressed by any means whatever. The natural treatment includes, everything that will promote elimination of the poison through the skin and other organs of depuration. If water is immediately accessible, a good, thorough scrubbing of the skin with soap and water, or, if in the open, with sand, tufts of grass, or any other, scrubbing material may be sufficient to remove the poison before it will do any harm; at any rate it will greatly reduce the bad effects.

The preliminary cleansing should be followed as soon as
possible by a whole sheet pack or a bed sweat bath, and cold Ablutions. This may be repeated several times if necessary, or followed by partial packs. Otherwise, the treatment is the same as for acute diseases. (Sec. VIII) Fasting and raw food diet are especially beneficial. The cold packs, compresses and ablations are the best means for allaying the intolerable itching and burning.

k) Antidotes for Acute Poisoning

By Lead: magnesia, soda or chalk water.

By phosphorus: thick liquid gum; white of egg; flour; bread magnesia and cold water, for the purpose of enveloping and isolating the poison. Do not give milk or liquids containing alcohol or oily matter.

By caustic acids, such as sulphuric, muriatic, carbolic or nitric acid: large quantities of soap, salt, chalk, limewater or milk.

By copper and verdigris, frequently contracted by foods or drinks prepared in copper vessels or by drinks from soda water fountains when the copper has become exposed through the away of the zinc lining: dilute white of egg; milk; water mixed with honey or sugar.

By Iodin: starch or flour paste.

By nitrate of silver: strong saltwater solution; white of egg.

By oxalic acid: chalk or lime water.

By strychnine: meat burned to a cinder; decoction of acorn coffee; tan or gall apple.

By arsenic: warm milk; sweetened water.

Scalds. (See Burns p.391)

27. Seasickness. The unpleasant sensations accompanying this disorder are undoubtedly caused by a disturbance of the center of equilibrium in close proximity to the, left ear, which in turn affects the entire nervous organism and especially the nerves supplying the digestive organs; causing intense nausea and vomiting.

So far no effective remedy has been discovered for this peculiar disorder. The following directions have in many instances either prevented or greatly alleviated its Symptoms.

Those who intend to travel on the sea should prepare themselves by a brief fast and light raw food diet. This should be continued on board ship. The heavy, rich, greasy foods served in overabundance on board of seagoing vessels undoubtedly have much to do with bringing on the gastric disturbance. The invigorating effects of a sea voyage might be greatly enhanced by a prolonged fast beginning a day or two
before taking passage and extending for a week or more, according to the vitality and recuperative powers of the individual.

The best remedy, aside from these dietetic measures) and according to my experience the most efficient, is getting into harmony with the motion of the vessel or car. Many times outside patients have come to me saying they could not continue coming for treatment because the benefits were offset by nausea and vomiting caused by the shaking of the cars. I have instructed the sufferers from ear sickness as follows:

Instead of tensing yourself physically and mentally against the violent vibrations caused by the rolling of the vessel or car, relax completely. Do not oppose and fight the motions but let yourself go with them. A good way to do this is to hum a tune in harmony with the oscillating motion of the ship or car.

In many instances the very first trial of my remedy has given relief and after a few attempts no discomfort whatever was experienced. Those who are naturally immune to car or seasickness probably practice this form of relaxation and rhythmic adjustment unconsciously.

It is another proof of the truth and practicability of the maxim of the Master, "Resist not evil". Those who most fear this form of evil and tense themselves against it are most affected by it, While the person who thoroughly enjoys sea travel and to whom the rolling of the vessel is a pleasure naturally relaxes to it, enjoys the sensation, and therefore feels no discomfort.

28. Shock is characterized by collapse and frequently by loss of consciousness. It may result from excessive loss of blood or physical injury, or it may be caused by emotional depression resulting from mental and nervous excitation such as sudden fright, grief, anxiety or anger. In many instances it is the shock rather than the actual physical injury which causes death.

If the collapse is due to haemorrhage, this must be stopped as quickly as possible (see p.402). Cool behaviour and reassuring suggestions are necessary to dispel fear and anxiety. The same tonic treatment must be administered as described under fainting, unconsciousness, etc., p.399.

Signs of Life. (See "Fainting", p.399.)

Snake Bites. (See "Bites", etc., p. 390.)

29. Sprains, Strains and Dislocations. Sprains and dislocations of joints must be attended to as quickly as possible by a competent physician, preferably a neurotherapist, osteopath or chiropractor. If, however, a physician is not immediately available and the injury results
in swelling, then cold packs must be applied to reduce the inflammation and to facilitate the adjustment.

If swelling, or pain, make it impossible to remove parts of the clothing or the shoes and stockings, these should be cut away with a sharp knife. The affected part must have absolute rest before and after the adjustment. Do not apply hot applications of any kind.

30. **Sunburns**, which are frequently the result of imprudent exposure in the sun-baths, are best treated by cold compresses and cold ablutions or by the olive oil and soda mixture.

31. **Sunstroke**. Sunstroke is caused by exposure to the direct rays of the sun in a heated atmosphere. Loss of consciousness is caused by the direct action of the sun's rays upon the brain and the cardiac and respiratory centers in the medulla.

a) The onset is sudden. The most prominent symptoms are unconsciousness, pallor, feeble pulse and rapid failure of the heart and respiration. Death is common, recovery often only partial, leaving the brain permanently injured.

b) Under the natural treatment few cases end fatally. The patient should be quickly undressed and cold water poured all over his body, also over the head. This should be followed by brisk salt water rubs; or the body should be wrapped in a wet sheet which must be kept wet by pouring cold water over it from time to time.

If collapse has taken place and vitality is greatly depressed, the patient must be put to bed and well covered with blankets so as to produce a warm reaction.

32. **Thermic Fever** may arise by night or by day through exposure to artificial or solar heat.

Premonitory symptoms are malaise, nausea, diarrhea, giddiness, sleeplessness, after which the temperature rises quickly to 108 to 110 deg F. or even higher. Prominent symptoms are lividity of the face, dispnoea and delirium. These are often followed by coma and death within a few hours. It recovery takes place it is slow and incomplete.

Cold, wet packs, followed by cold ablutions, must be applied. The drinking water should be cool and mixed with acid fruit juices. (See the usual treatment for acute diseases, Sec. VIII.) Under natural treatment few cases end fatally.

**Toothache**. See Section XLIII, No.8, p.430.

33. **Transporting an Injured Person**. To lift or carry an injured person in the wrong way may cause permanent injury or even death; therefore, care fully examine the victim of an accident in order to ascertain whether he has sustained a fracture or serious internal injury.
First aid should be administered at once and on the spot; but if removal is necessary, a stretcher may be improvised out of a board, a door, bedspring, or anything else convenient for the purpose (Fig. 49, p.418). Care must be exercised not to drop the injured one. If a patient must be transported by carrying, the following methods will be found practical:

**a)** If the injured one can walk, let him put his sound arm around your neck and with one hand grasp his hand hanging down from your shoulder and with your other arm firmly support his body. (Fig. 46).

![Image](image.png)

If the patient is unconscious, the following methods will be found most convenient:

**b)** You may carry the patient in an upright position, placing your right shoulder under his armpit and your right arm around his waist, his left arm back of your own neck and over your shoulder, taking hold of his left wrist with your left hand. In this way you can either help him walk, as previously described, or carry him entirely. (Fig. 46)

**c)** If an adult person is unconscious and requires immediate removal, it would be impossible for one person to carry him in his arms. In such an emergency, the pick-a-back method is the most practical. Stoop down and place the patient well up on your back; then pass your right arm around his right knee and with the other hand grasp firmly the wrist of his right hand drawn over your left shoulder. In this way he is in a safe position to be carried for a considerable distance and the weight is fairly distributed and balanced over your back and shoulders.
d) The third method of carrying an unconscious person is similar to (c), the only difference being that your right hand after passing around the upper part of the right leg of the patient, grasps his right wrist, drawing his right arm over your left shoulder and firmly across your chest, as illustrated in Fig. 47 above. This position leaves your left arm free for other employment, if desired.

e) If two persons are available for transportation they may support the injured one on their locked hands, while he places his arms about the necks of his carriers. (Fig. 48)

f) Fig. 49, illustrates an improvised stretcher. Two poles have been slipped through the sleeves and body of two buttoned coats. Other improvisations may be made by means of a board, door, shutter, mattress, etc.

SECTION XLIII

CARE OF THE TEETH

1. Disease of the teeth generally speaking, is the result of two causes: First, malnutrition, which causes deterioration and
destruction of the teeth from within; second, corrosion, caused by systemic acids and other corroding substances which attack, from without, the enamel of the crown and the hard covering of the neck and roots.

Dentists and books on hygiene deal almost exclusively with the last named factor. They have a great deal to say about the regular and thorough cleansing of the teeth, and of dental treatment, but seldom mention the influence of food materials, nutrition and constitutional disease on the condition of the teeth.

That this is not as it should be is proved by the fact that animals living on natural food, as well as savage races, and people who live in primitive surroundings and subsist largely on products of the soil not demineralized and devitalized by modern manufacturing processes, have splendid teeth and retain them to the end of life without tooth brush, dentifrice or the attention of a dentist.

The teeth of animals and humans who live on natural food well adapted to their needs, gradually wear off to the gums with advancing age but do not decay or fall out; neither are they troubled with abscesses, pyorrhea or other diseases produced by unnatural and artificial ways of living.

Regular examinations of children in our public schools disclose the fact that in spite of tooth hygiene taught in the schools and enforced in the homes, eighty-five percent or more are suffering from defective teeth. Of 1694 children examined in six clinics during the year 1913 by Dr. A. F. Foot, only eleven were found to possess normal teeth. Dr. Foot reported to the Second District Dental Society of New York as follows.

"The six-year molars of nearly every child were broken down wholly or in part. In many instances the molars were decayed to the gums. So extensive and far advanced were the defects that corrective treatment, even if it were applied, would have been of little value."

2. This almost universal decay of the teeth is caused:

1. by wrong food combinations;
2. by devitalized and demineralized food;
3. by the action of corrosive substances from within and without;
4. by the softness of the food materials and by their excessive heat and coldness;
5. by hereditary and congenital influences.

Examining these pathogenic factors separately we find that the ordinary diet customary in the home, hotel, restaurant and boarding house, consisting almost entirely of cooked foods, is excessively rich in starches, sugars, fats and proteins, but very deficient in the mineral salts. This is true of these foods even in their natural condition, as they come from the soil; but the
discrepancy between negative food elements and positive 
mineral elements is much greater after the cereals rice, 
sugarcane sap and beet sap have passed through the modern 
milling and refining processes. These leave the white flour, 
polished rice, decorticated corn products, pearled barley, corn 
starch, white sugar and corn syrup in a devitalized and 
demineralized condition. Together with the all-important 
mineral elements, the foods have been robbed also of their 
vitamins or life elements. What little is left of the vitamins is 
destroyed and dissipated by boiling, roasting, frying or 
fermenting.

Unnatural food combinations, which predominate in acid 
and pathogen producing negative food substances and are 
very deficient in the acid neutralizing and eliminating mineral 
elements or alkaline bases, produce excessive amounts of 
acids, ptomains, leukomains, xanthins and other pathogenic 
substances which corrode and tear down the outer enamel 
covering and internal dentine structure of the teeth.

The destructive effect of acids upon bone tissue can readily 
be demonstrated by submerging a piece of bone in 
hydrochloric acid. Within a few days the lime salts 
constituting the solid framework will be dissolved and 
abstracted, nothing being left but a soft cartilaginous and 
gelatinous mass. Submerge an eggshell in strong vinegar; 
within a few days it will be completely dissolved. In similar 
manner, acids in the blood and mouth fluids, and acids which 
form in decaying matter clinging to the teeth and in the hollow 
spaces between them, will gradually destroy the enamel and 
dentine.

Refined sugars act very much as do acids. Having been 
robbed in the refinery of their positive mineral elements, the 
remaining negative elements, hydrogen, carbon and oxygen, 
by chemical affinity leech the minerals from the bones and 
tissues, thus causing gradual decay.

The sturdy Scots owe their tall and large boned bodies to 
the highly mineralized cereal, fruit and vegetable products of 
their mountain valleys, the soil of which is enriched every 
season by the mineral wash from the rocky hillsides.

As long as they lived on whole meal barley bread and 
oatmeal porridge made from homegrown and home milled 
cereals, they had splendid teeth. During the last few 
generations, however, since they commenced to abandon their 
primitive foods for white bread, white sugar and devitalized 
breakfast foods, dentists have become more numerous among 
them.

3. Gingivitis and Pyorrhea. These ailments are so 
injurious, not only to the teeth, but also to the general health 
of the body, and they are increasing in frequency with such 
alarming rapidity that they deserve special attention.

Allopathic medical science declares that gingivitis and
pyorrhea, like all other inflammatory diseases, are caused by germs, and has vainly tried to cure these common ailments by the application of antiseptics and germ killers. We find that as usual the germs are secondary effects, that we must look for the true causes in other directions. These are:

1) Lack of exercise for the teeth and the connective tissues which hold them in place.

2) Inflammation of the gums, caused by hyperacidity of the system and other pathogenic conditions.

3) The corroding action of mineral deposits on the teeth.

Dr. Robert Aiston, a prominent Chicago dentist, who for twenty years has made pyorrhea a special study, says he is positive that lack of exercise for the teeth and the connective tissues which hold them in place, is the principal cause of pyorrhea.

In an interview I had with him lately on the subject, he said: "No man living has made a more exhaustive study of pyorrhea than I have, and I am convinced that the principal cause is the predominance of soft, mushy, cooked food in the customary diet of our American people."

The reasons with which he backs his opinions are very convincing. I shall condense them in the following paragraphs.

The roots of the teeth are held in place by ligamentous tissues and these remain strong and sound as long as they are subjected to normal strain from the push and pull exerted by vigorous mastication. When this ceases, as a result of the continuous consumption of soft, cooked foods, then the dental ligaments and other connective tissues begin to weaken and decay. Stagnation and putrefaction set up inflammation, this produces inflammatory exudates rich in calcareous salts and these in turn form seruminal calculi on the roots of the teeth, so called because these mineral encrustation's are precipitated from the blood serum. The doctor showed me a number of teeth which were thickly covered with these rough, earthy deposits.

I fully agree with Dr. Aiston that local stagnation, due to lack of exercise, is one of the primary causes of inflammation and destruction of the dental ligaments, but I believe that this is greatly facilitated and aggravated by pathogenic materials and disease taints in the circulation, and in the very beginning by mineral encrustation's on the surface of the teeth.

Elsewhere I have mentioned that in several cases pyorrhea entirely disappeared after the patients had been cured, by natural methods, of smallpox, gonorrhea, syphilis and other acute, eliminative diseases. Healing crises eliminated the disease taints; raw food diet reduced the "calcareous exudates" and scoured the teeth of slimy and earthy
In this connection I should mention that after the adoption of a raw food diet mineral deposits on the teeth at first increase. This is caused by the neutralization of large amounts of acids. But as the acidity, under the influence of alkaline diet, diminishes, mineral precipitation ceases, inflammation subsides, the encrustation's on the teeth are gradually absorbed and the gums have a chance to heal.

Pyorrhea, as well as other chronic ailments, can be cured only by restoring the entire organism to a clean, normal condition.

**Gingivitis.** The mineral deposits on the crowns of the teeth, usually light, gray in color, are commonly called tartar. Dentists speak of them as salivary calculi, because they are formed by earthy precipitates from the saliva. These tartar deposits may encroach under the borders of the gums, and this, together with slimy, mucoid accumulations, gives rise to inflammatory, destructive processes in the gum tissues. This is commonly called gingivitis. It is the forerunner of pyorrhea. The only difference between the two ailments is that in pyorrhea the mineral deposits form on the necks and roots of the teeth, and that these seruminal calculi, are blacker, harder and more destructive than the tartar on the crowns. The sharp earthy crystals help to corrode the dental ligaments, aggravate the inflammatory processes, and thus in turn increase the inflammatory exudate of calcareous matter. Filthy, putrefying matter could not accumulate around the teeth and under the gums if the food contained sufficient coarse, scouring material.

Thus it will be seen that the two causes, stagnation due to lack of exercise, and mineral precipitation due to hyperacidity of the system, seesaw in the causation of gingivitis and pyorrhea.

**The Rational Treatment of Gingivitis and Pyorrhea**

It is well enough to scrape from the teeth the earthy encrustation's which cause the gums to recede and to putrefy, but what good does this when the hyperacid condition of the system makes new deposits?

Many people have the idea that they can safely eat meat, eggs and large amounts of starchy foods as long as they consume with them plenty of the mineral salt foods, such as fruits and vegetables. As explained in Vol. I of this series, in Chapter XXIX, this is a mistake. The intake of too much starchy and protein food leads to the excessive production of acids and other pathogenic substances. Though these are neutralized by alkaline mineral elements, more earthy salts are thus formed than can be properly eliminated through the skin and kidneys. These salts collect on the teeth as tartar, or they may form deposits in the joints resulting in rheumatism.

4. **In order to prevent** these and a host of other acid diseases, it is not enough to adopt a vegetarian diet, but the
intake of vegetables, starches and proteids must be kept within normal limits. How to accomplish this I have explained under the heading of food combinations in Section 1, No. 10, pp. 23, 24.

Normal consistency of the food also has much to do with the preservation of the teeth. The perfect condition of the teeth of wild animals and of primitive man is partly due to the fact that they consume their foods in the natural raw condition, thus giving the teeth plenty of wholesome exercise by the gnawing, grinding and crunching of bones, grasses, raw cereals, fruits and nuts. While savage or primitive people cook some of their food, they use much more raw food than do their civilized cousins.

Cooked food, in which most of the vitamins have been destroyed, is much more prone to acid formation than live, raw food. Physicians and dentists frequently warn against acid and sub acid fruits "because they destroy the enamel of the teeth." This is a mistake. The live organic acids of fruits and vegetables, charged with vitamins, have not a destructive effect upon the bony structures as do the disease producing acids formed by abnormal food combinations and putrefactive processes. The malic and citric acids of the fruits are highly organized and help to dissolve the earthy deposits in the joints, and the tartar on the teeth. (See footnote page 434.)

**Unless the diet contains liberal proportions of raw vegetables, fruits, roots and nuts, which are splendid natural scourers and cleansers, the teeth are bound to deteriorate and decay.**

Even the teeth of cows become loose and fall out when the animals are fed continually on the soft, sloppy, devitalized and demineralized cereal offal of breweries and distilleries.

To begin the day and to end it with the munching of an apple or some other raw fruit or vegetable relish, is the best way to keep the teeth in a perfectly clean and sound condition.

Another reason why dentistry in civilized countries is one of the best paying professions, is the habit of swallowing food and drink, either very hot or extremely cold. Not infrequently the piping hot soups and other viands are washed down with ice water or immediately followed by ice cream, sherbet or other chilled desserts.

The sudden expansion and contraction due to contact with excessive heat or cold causes the enamel to crack and thus exposes the dentine of the teeth to the destructive activity of acids and other corroding substances.

When prospective parents have destroyed their teeth by unnatural practices, how can they expect to produce offspring with sound bones and teeth? When the blood of the mother is utterly deficient in the bone building mineral elements, is it any wonder that the new born comes into the world
handicapped for life with a dwarfed, defective bony framework? The formation of tooth substance begins in the embryo after the sixth week and continues all through gestation. This further reveals how important it is that the food of the mother contain sufficient amounts of the bone and teeth making elements. This is possible only when her diet includes an abundant supply of fruits and vegetables, hulls of grains and other mineral salt foods; classified under Group V of the food Table, page 33.

I have observed in many instances that when the prenatal structure and chemical composition of the teeth is abnormal, natural feeding after birth cannot always make good for the defective foundation. An imperfect, cankered Seed will not produce a perfect tree, even though the soil it grows in contains abundant nourishment.

5. Cleaning the Teeth. By the foregoing I do not wish to depreciate the importance of keeping the teeth in a clean and sweet condition by careful scrubbing several times a day, particularly in the morning and before retiring. If convenient it should be done after every meal.

However, we do not favor for this purpose the use of preparations containing poisonous antiseptics. These are readily absorbed by the tender tissues of the mouth and in time will cause trouble in the body. Practically all tooth powders, pastes and lotions sold in the drug stores contain such deleterious substances. These are not only decidedly harmful, but entirely superfluous because the best tooth wash is fresh, cool water made slightly acid with lemon juice. Brisk scrubbings of the teeth with this natural dentifrice will keep the gums and teeth in clean and sweet condition. This should be followed by rinsing the mouth with fresh water. The scrubbing should be done from above downward and from below upwards. This will tend to pull the gums over the teeth and to cleanse the crevices between the teeth from food particles and slimy accumulations.

Another good treatment is to dip the forefinger into cold water and give the gums, inside and outside, a good rubbing and kneading. Always finish by rinsing the mouth thoroughly with water as cool as the gums will endure.

If there is a tendency to the formation of tartar the teeth may be thoroughly scoured a few times a week with ground pumice stone, whiting or oyster shell, but this must not be repeated too often because it might injure the enamel.

It goes without saying that the teeth should be looked after by a competent dentist at least every six months, and that defects of any kind should be attended to promptly. Many a tooth can be saved by a timely filling, a well fitted crown, or good bridge work. These matters must be left to the skill of the dentist. The better he understands his art, the more economical will be his services in the long run.
6. Foci of Infection and their Suppression. The latest theory of medical science is that rheumatism and a number of other acute and chronic diseases are caused by germ infection from suppurating tonsils and adenoids, from abscesses in the teeth and ulceration and pyorrhea of the gums. These shortsighted deductions are the natural outgrowth of the germ theory and of the local and symptomatic conception of disease.

We find in our institutional work that the aches and pains of rheumatism, headaches and asthmatic spasms, etc., come and go, rise and fall in exact proportion to the increase and decrease of acids and other pathogenic materials in the circulation. I do not deny for a moment that the pathogenic materials in these foci of infection may start or aggravate acute conditions in other parts of the organism, but is it sufficient to suppress the foci of infection with antiseptics and surgical treatment? The question is, what causes the foci of infection, the suppurating tonsils and adenoids, the abscesses in the teeth, the ulcerating gums and jawbones?

Does medical science imagine that the suppression of these foci of infection with poisonous antiseptics and surgical operations solves the problem? Why cannot they see that this also is rank suppression and not Cure? Why cannot they see that this also is rank suppression and not Cure? Can a healthy body, endowed with pure blood, normal tissues and perfect mechanical structural alignment, develop such foci of infection? What is the use of suppressing these symptoms of constitutional disease in one place and having them bob up at another place in more destructive form? Of such nature are the great achievements of modern medical science.

7. This latest craze has led in innumerable instances to the pulling out of whole sets of teeth because one or more were abscessed or because of the presence of so-called pyorrhea, which frequently is nothing but a raw condition of the gums induced by encrustation's of tartar on the roots of the teeth. I meet almost daily with people who have been robbed of sound teeth, sometimes of entire sets, on the assumption that it would cure their rheumatism or other constitutional diseases. To their sorrow they find that the cruel sacrifice has brought no relief so far as their chronic ailments are concerned.

Such criminal experimentation is on a level with tearing out sound ovaries with the idea of curing epilepsy or other chronic diseases. I have known of a number of such uncalled for mutilations. In no instance has the unnatural treatment benefited the patient; it has only served to aggravate the chronic ailment and to hasten physical, nervous and mental breakdown.

The constant suppression of symptoms of disease by drug poisoning and surgical mutilations creates chronic invalidism, hereditary disease, and defectives. Is it not more rational to put the system, through natural living and treatment, in such a pure and wholesome condition that it cannot develop inflammation and suppuration of the tonsils, teeth, gums and
jawbones? Such is the practice of the new school of healing.

8. Toothache. One of the most excruciating tortures that man inflicts upon himself by wrong living, is the toothache. All the causes I have enumerated and described help to create it, and avoidance of these causes is the best prevention.

There are two general types of toothache, the acute inflammatory, accompanied by heat and swelling, and the cold neuritic or neuralgic.

a) The acute inflammatory may be due to congestion and irritation of the blood vessels and nerves of a tooth or row of teeth by systemic poisons, in the same manner that inflammations arise in other parts of the system as the result of pathogenic obstruction and irritation. Acute inflammation may arise when the nerve of a tooth becomes exposed through decay of the bony structure. In that case the attention of a dentist may become necessary. But care must always be taken not to cover decaying particles with a filling or crown. The parts to be covered must be carefully cleansed of all materials that might cause further putrefaction.

b) Treatment. The acute inflammatory toothache is best treated by retaining cool or cold water in the mouth until it warms up, when it should be spit out and replaced. At the same time cooling compresses or packs should be applied to the cheek on the affected side. The pack as usual consists of a piece of muslin, folded from three to six times, and wrung out in cold water. The cold compress is then covered by one or several folds or dry flannel or woolen cloth. The compress or pack may be kept in place by one of the bandages described on page 390.

An acute congestive toothache may be greatly relieved by gentle downward massage movements along the veins and lymphatics in the neck. Thorough drainage of these vessels will do much to relieve the congestion in the affected parts. While giving the massage movements, also use your mental power to combine with the mechanical treatment the magnetic effects. Osteopathic, chiropractic and naprapathic treatments prove very effective in many cases.

In serious attacks the local water treatment may be reinforced by a whole sheet pack, bed sweat bath, or body or leg packs followed by cold ablutions (Sec. XV, p. 147). During the night the sufferer may at intervals take a cold rub and go under the bed covering without drying. All these water applications draw the blood away from the congested area into the surface and thus relieve the local congestion and excruciating pain. They also promote the elimination of the pathogenic materials which are the primary cause of the trouble.

If acute inflammation within and around the teeth were always treated in this way it would seldom come to the formation of acute or chronic abscesses. The pathogenic
materials would be absorbed and eliminated immediately.

Of equal importance with the water treatment is fasting. From the first appearance of a toothache, absolutely no food should be taken until it has ceased entirely, and even then the fasting should be continued for a day or two in order to clear up the constitutional condition which caused the local inflammation. Fasting alone in many instances has cured the severest toothache.

I would **warn strongly against the use of poisonous pain killers.** They only serve to paralyze the nerves and do not in any way remove the underlying causes of the trouble. They add drug poisons to disease poisons and thereby accelerate destruction of the teeth and the gums.

c) **Neuritic Toothache.** This type of toothache is not accompanied by great heat and swelling as is the inflammatory kind. It is usually caused by the exposure of a nerve, or by the irritating effect of some systemic or drug poison. If caused by defects of the teeth and by exposure of a nerve, proper dental attention is of course indicated.

This type of toothache is much more stubborn and does not yield to treatment as easily as does the acute inflammatory kind. Cold water, magnetic and manipulative treatments give but momentary relief. The reason is that the pain will continue or will return at intervals until the poisonous irritant is removed or until the nerve is killed or protected. Sometimes the jaw bones and cheek bones are more affected by these neuritic toothaches than are the teeth themselves. This is usually due to the action of some irritating poison.

d) **Treatment.** In these cold, persistent forms of toothache, hot applications sometimes give better relief than the cold applications, though the relief is temporary.

A remedy worth trying when cold treatment fails, consists in the application of a muslin bag partly filled with hot salt and held in place by a bandage. The salt should be as hot as it can be endured.

The only way these neuritic toothaches can be permanently cured is by eliminating the poisons which are at the root of the trouble.

In many cases we have found mercury, iodine, arsenic, quinine, or other drugs to be the real cause of the disturbance.

Elimination of these hidden enemies can be accomplished only by thorough systemic treatment and natural methods of living.

Many dentists are in the habit of using large doses of iodine, arsenic or other powerful poisons for killing the nerves. They should be warned not to use any more of these destructive poisons than is absolutely necessary. If the work
can be accomplished without using them at all, so much the better.

I would also warn strongly against amalgam fillings. The amalgam or silver filling, so called, contains about 50% of mercury. Acids in the blood and in the fluids of the buccal cavity have a tendency to dissolve the mercury and to create bichlorid of mercury and other mercurial salts which will accumulate in certain parts of the body for which they have a special affinity, particularly in the brain and spinal cord. I am aware that such warnings are pooh-poohed and ridiculed by many dentists, but practical experience tells a different story. The blackening of the teeth indicates formation of mercurial salts. In numerous cases, we have observed pronounced symptoms of mercurial salivation, such as metallic taste in the mouth, ulceration about the necks of the teeth, fetid breath and abnormally increased flow of saliva, which did not disappear until the amalgam fillings were removed from the teeth and replaced by gold, or porcelain. Gold filling, whenever it is practicable, is undoubtedly the best of all.

I know skilled dentists who have discovered these facts for themselves in the course of practice and who have discontinued the use of amalgam fillings on this account.

Of late I have met with several cases of paresis which showed distinctly the sign of mercurialism in the iris. Inquiry revealed the fact that these patients were dentists who for many years had been in the habit of mixing the amalgam and alloy in their bare palms. Mercury had thus been absorbed and was responsible for the destruction of brain substance.

Referring to statements made in section XLIII. 1. In the last paragraph I call attention to the fact that acids act differently on dead and living tissues. The hydrochloric acid secreted by the stomach in normal solution does not affect this organ injuriously, while it readily decomposes the stomach of a dead animal. The same principle holds true in relation to the action of fruit acids on dead and live teeth.

SECTION XLIII

WHY GROW OLD?

"What a question," you exclaim. "We grow old because we cannot prevent it; because Nature has decreed it so."

Of course we shall grow old in years but if we live in harmony with Nature's laws we need not grow old in mind or heart nor lose our physical energy and our alertness and suppleness of body and mind long before the expiration of our allotted time. While growing older in years we should grow younger and more robust as far as our intellectual, emotional, moral and spiritual qualities are concerned.

As regards longevity and the possibility of retaining our
youthful qualities to very old age, we meet with two extremes of opinion. Many mental scientists and new thought people tell us in their lectures and writings that it is not impossible to achieve immortality and perpetual youth in the physical body on this earth plane; that we die long before our time because we imagine we must; that a short-lived existence was necessary for animals and human beings in the early stages of evolutionary development, but that now since the physical body has become more perfect the necessity for dying has passed away and that as soon as we can exterminate the old age and death thought which has become race habit, the "last enemy" will be vanquished and immortality and perpetual youth in the flesh will become the common heritage of human kind.

The majority of mankind entertains an entirely opposite and somewhat pessimistic opinion as regards longevity and the preservation of youth. They are convinced that growing old and decrepit, that losing the enthusiasm, beauty and efficiency of youth is inevitable. They argue that growing old or dying young, health or disease, depend upon heredity, environment, colds, drafts, germs and other accidental circumstances over which we have little or no control. One prominent physician recommended the chloroforming of people over sixty years of age. These two opposing views were brought home to me quite vividly some time ago, while attending a lecture by a well-known mental scientist. His subject on this occasion was "Perpetual youth".

In alluring language, scintillating with plausible argument and beautiful metaphor, he proved to his own satisfaction the possibility of perpetual youth and life everlasting in the physical body. After the audience had given fervent expression to its approval of his lofty idealism, an elderly gentleman in the audience arose and delivered his views on youth and longevity in a pessimistic wail that was taken in shorthand by a stenographer present in the audience.

"This subject of perpetual youth as put forth by our speaker is a beautiful theory. It is a wonderful theory, but I am very clear that it does not work out in life. I do not believe there is such a thing as perpetual youth. It is an ideal belief. You cannot by any process known to human science or human ingenuity turn back the wheels of time or stay them in their revolution."

"This fountain of perpetual youth old men have sighed for, old women have prayed for, and in search for it from time immemorial young women have appropriated their husbands wages and poured their money into the cash box at the drug store; but they have never yet found it."

"It is true that by right thought and right action you can probably postpone old age, but you can postpone it only to a very limited degree. The speaker stated that seventeen hundred people in the United States had reached the age of one hundred years, but he did not tell you how many of them
are paralyzed, how many of them are palsied, how many are more dead than alive.

"He tells you that with advancing age the arm of the blacksmith grows stronger. This is true for a certain time, but its strength reaches its zenith, then it grows weaker and weaker until it hammers no more. Young man, you cannot turn back the wheels of time and you cannot stay their revolutions. The time that is past is laid to rest in eternal sleep; it is buried in the mysterious realm of oblivion.

"Time robs the bridal wreath of its beauty. Time writes wrinkles upon the brow of the aged. You may wreath, garlands and place them around the brow of youth, but the onward march of time sees them wilt and mingle with the dust.

"The birds that sing so sweetly will return in the spring. The flowers will return and bloom again, but, ah, my friends, youth is gone. It is past forever. It never returns, but age is real and forever-perpetual youth is no more than a beautiful dream."

As regards the possibility of life everlasting on this earth plane, I for my part would gently but firmly decline it. The idea of living in the same old place forever and forever is not attractive to my mind. I imagine in time it would become too monotonous.

To me, life is a great school; a school of personal effort for the development of our latent god-like faculties, capacities and powers. This school takes in all there is in the sidereal universe. Its course in length of time is eternity; its classrooms and laboratories are the solar systems and their planets. Whenever we have learnt all there is to learn; all there is to be acquired of knowledge, wisdom and experience in this great school of life, then it will be time for us to die. The only death I know of is stagnation and retrogression. Life is growth; growth is change, continual, perpetual change—senescence and rejuvenescence, as science calls it. Death is only a phase in this continuous process of change.

The majority of mankind look upon death as the greatest evil in life. They think of it with despair and terror. Some commit suicide because they are afraid to die—a strange paradox, inspired by fear, fear of something that is in reality the greatest of all blessings, the birth into a new and brighter world with new life, new youth, new and broader possibilities, after we have acquired all there is to be learned in one brief earthly pilgrimage.

Why grieve for the loss of loved ones who have made the great transit before us? Shall we not be glad to meet them when we arrive on the other shore? If we had to travel on a long journey to a foreign country, wouldn't we be pleased to meet with friends among strangers in a strange land?
Life on earth is only the kindergarten in the great school of the universe. Even the greatest and wisest of men that live on this earth are only in the lower grades of the great Cosmic University. Why should we fear to pass on? Nobody would like to remain in the primary grades all his life when there are so many more interesting, useful and beautiful things to be learned in the higher grades.

One New Thought philosopher argues that immortality in the flesh, or at least a prolonged term of life on this earth, is necessary in order to acquire all there is to be learned and experienced in this beautiful world of ours and in order to permit the law of compensation to work out the great chain of cause and effect.

How much more reasonable and beautiful than this idea of continuous existence on earth is the philosophy of Karma and reincarnation of the ancient wisdom religion. Is it not better to have the arduous training of earth life alternate with vacations in the spirit land, and to return oblivious of previous existence's with their depressing burdens of errors, sins and sorrows? Thus death on one plane of life becomes birth into another, and vice versa.

In this continuous change from the old age of one life to youth in another life, lies for me the true solution of rejuvenescence, of immortality and of perpetual youth.

If we look upon life from this higher and brighter viewpoint, how can we grieve at growing old? How can we fear death? Those who are in conscious touch with life on the spiritual planes tell us that beings of high spiritual development appear in a condition of youthful maturity, combining the wisdom of millenniums of spiritual and celestial existence with the beauty of perpetual youth. It is not knowledge, wisdom and experience that causes premature senility and death, but wrong thinking, feeling and doing. Aside from unnatural physical habits of living, nothing promotes senile decrepitude like fear of disease and death, bred through ignorance of life's great laws.

He who looks at life from the higher and brighter viewpoint enjoys advancing life in ever greater serenity of soul and happiness of spirit. He rejoices in ever greater expansion of mind and deeper understanding of life's mysteries. He is justly proud of every year added to a life of usefulness to himself and to his fellow beings. Such a one has only pity for the pessimist's wail previously recited. Such gruesome thinking and feeling is the very essence of black magic that ages and stiffens the body and pencils wrinkles on the brow.

To grow younger as we grow older, we must practice white magic. The body is an electrotype of our mental images. Physical matter convolutes to the mental and psychical or soul pattern. "As a man thinketh in his heart, so is he," or as Gautama Buddha expressed it, "I am today what my past
thoughts and feelings have made me."

See yourself in your mind's eye as always beautiful, vigorous and active, as in the prime of youth, for "A man is never older than he feels, and a woman never older than she looks." "But", you ask, "how shall we keep our looks young?"
That is simple. Bathe daily in the sparkling waters of serenity of mind and of cheerfulness and in the milk of human kindness. Learn how to relax completely in body, mind and soul and never entertain discordant and destructive thoughts and emotions.

Physical Causes of Senescence

Mental magic alone, powerful as it may be, is not sufficient to prevent the aging of body and mind. We must also live in harmony with the laws of the physical. No matter how good a watch you have, if you allow it to fill up with dust, dirt and corroding acids, it will soon lose time and finally stop entirely. This is exactly what happens to the human clock when it "grows old".

As philosophy has two divergent opinions concerning the prolongation of life, so has physical science two theories concerning the causes of senescence or senile deterioration. According to one of these theories, the animal and human being is endowed at birth with a certain amount of vitality, or with a certain momentum of vital force. When this is gradually spent in course of time our powers begin to wane; as a result of lowered vitality the vibratory power to expel waste declines; blood and lymph vessels become obstructed, joints stiffen, brain and nerve matter hardens and we grow old and decrepit.

Certain facts in Nature favor this viewpoint. Even under the most favorable conditions in the freedom of Nature animals live only to a certain age limit. Each species and family of creatures seems to have its own allotted lifetime or age limit. When this limit is reached they suddenly decline and die. I say "suddenly" advisedly. They do not spend a third or a half of their lifetime in getting old and in dying like the average human being. They retain their full vigor and beauty of form almost to the end of life. It is of rare occurrence that a hunter kills an animal that is found to be diseased or deformed. Among antelope, deer and elk the oldest bucks are usually the leaders of the herd. In order to maintain their supremacy they must fight and vanquish their younger rivals.

So human beings when living the natural life, physically, intellectually, morally and socially, will reach the no limit fixed by Nature for the human species in full possession of their faculties, capacities and powers, and will depart from life peacefully. Death will be as painless and sweet as sleep. I believe that in higher reaches of evolutionary development yet to be attained by mankind, the transition from earth life into spiritual life will not mean the passing "through the valley of the shadow" but that human beings will make the transition in
full possession of their waking consciousness.

The opposite theory advanced by physical scientists as regards the causes of senescence, postulates that vital energy is generated by the cells, tissues and organs of the body, and that as these with advancing age deteriorate and disintegrate, vital energy ceases to be generated and the constituent elements of the body become unfit to carry on the vital activities.

Natural Therapeutic philosophy teaches that the physical body is an instrument for the manifestation of the great life force which is divine life, intelligence and creative power. God or Nature evidently does not intend us to live on this earth forever in one continuous stretch of life and therefore has wisely limited the supply of vital force as well as the durability of the physical body in accordance with the laws governing incarnation and reincarnation on the physical and spiritual planes of life.

As before stated, even the healthiest animals living in the most congenial surroundings in the freedom of Nature do not much exceed their allotted span of life, nor do they fall much below it. As a rule, the longer the period between birth and maturity, the longer the life of the animal.

All the different families of mammalia, when living in freedom, live closely up to the life period allotted to them by Nature. Man is the only exception. It is claimed that according to the laws of longevity his average length of life should be considerably over one hundred years, while according to life insurance statistics the average is at present about forty years. This shows an immense discrepancy between the possible and the actual longevity of man.

Even this brief average span of life means for the majority of mankind little else than weakness, physical and mental suffering, premature senility and death. Visiting physicians of the public schools in our large cities report that seventy five per cent of all school children show defective health in some way. Diagnosis from the eye proves that the remaining twenty five per cent are also more or less affected by hereditary and acquired disease conditions. Christian Science says, "There is no disease". Nature's records in the iris of the eye prove there is no perfect health.

These established facts of greatly impaired longevity and universal abnormality of the human race would of themselves indicate that there is something radically wrong somewhere in the life habits of man, and that there is ample reason for the great health reform movement which was started about the middle of the last century by the pioneers of nature cure in Europe and which has since swept, under many forms and guises, all portions of the civilized world.

When people in general grow better acquainted with the laws underlying prenatal and postnatal child culture, natural
living, and the natural treatment of diseases, human beings will approach more closely the normal in health, strength, beauty and longevity.

However, to reach this ideal of perfect physical, mental and moral health, succeeding generations will have to adhere to the natural ways of living and treating their ailments. It cannot be attained by the present generation. Those enthusiasts who claim that they can, by their particular methods, achieve perfect health and live the full term of human life are destined to disappointment. We are so handicapped by the mistakes of the past that the best which most of us adults can do is to "patch up", to attain a reasonable measure of health and to approach somewhat nearer Nature's full allotment of life.

Growing old consists in the accumulation of waste and morbid matter, earthy deposits, destructive acids and alkaloids, causing the stiffening and hardening of joints, bones, veins and arteries and the gradual loss of physical and mental energy.

Do you ever stop to think how this clogging and corroding of the wheels of life is promoted and accelerated by wrong habits of eating and drinking? Food chemistry as taught by the school of Natural Therapeutics clearly shows that excessive use of starchy and proteid foods is the most prolific cause of disease and of premature old age. These classes of foods create in the body a large variety of destructive acids, ptomaines and alkaloids, such as uric acids, sulphuric acid, oxalic acid, indican, xanthins, creatin, etc.

Flesh foods especially favor these morbid accumulations because they are already saturated with all the waste products of the animal carcass. The poisonous xanthins of coffee and tea are almost identical with uric acid. While at first they over stimulate the organism, the second and lasting effect is to benumb and paralyze heart and nerves and to retard elimination, thus causing directly and indirectly retention and accumulation of waste matter in the body.

For these reasons, we of the Natural Therapeutic school realize that the only way to keep the system pure and sweet and its vibratory activities vigorous and harmonious is to reduce in the daily dietary the allowance of starchy and proteid food and to use a larger proportion of fruits and vegetables whose alkaline elements tend to dissolve and eliminate the acid crystallizations and deposits in the tissues.

This becomes more imperative as we grow older. A young and growing body, physically active in play and sport, needs a great deal of sugar and of proteid to furnish fuel and to feed and repair the rapidly growing and changing cells and tissues.

When we pass the meridian of life, growth ceases; there is much less physical activity and therefore much less need of starchy, fatty and albuminous elements. Therefore, as we advance in years these foods should be reduced in amount and
replaced by the dissolving and eliminating fruits and vegetables, but conventional habits and the doctor's advice usually favor the opposite course.

"You are growing older," says the doctor; "you must have plenty of strengthening foods—meats, eggs, fish, fowl—and you need some stimulants. Coffee or tea is all right and an occasional glass of beer or of "Duffy's Old Malt" won't hurt you, either."

Frequently a patient tells us, "All the young people in our house are now living on the natural diet, but you know father and mother are growing old and they must have their soup and meat, their coffee and beer; in order to keep up their strength."

Reverse the prevalent ideas on hygienic living and you are just about right; so in this regard the very opposite policy should be adopted. The older we grow, the less we need of the heavy, clogging foods and the more of the light and purifying.

The majority of people eat too much anyway. Habitual stuffing practiced through many generations has made it second nature. Many consume the best part of their available vital force in endeavoring to digest and eliminate superfluous quantities of food and drink. Every ounce of food in excess of actual need wastes vital force.

A Roman proverb said: "Plenus venter non studet libenter"—a full stomach does not like to study.

Vital energy required to remove useless ballast cannot be transformed into physical or mental energy. Vital force is a primary force. It cannot be eaten. It comes from the source of all life and is independent of the physical body just as electricity is independent of the bulb which it fills with light. Food can only furnish fuel material for the flame of life and keep the human organism in such condition that vital force can manifest itself in it and through it. If food and drink could give life they should prolong it indefinitely; in that case the glutton and drunkard would live the longest, but common experience teaches us that the man temperate in all things best preserves his physical and mental vigor and lives the longest.

The beauty about all this is that nature cure philosophy does not confine itself to visionary theorizing, but that it "delivers the goods". If we can take all sorts of chronic incurable diseases and within four or five months or a year's time work a wonderful transformation and actually cure the majority of such patients and give them a new lease on life, why should it be impossible to prolong life to its natural limit and to retain to the last, unimpaired, our faculties, capacities and powers of body, mind and soul?

How much greater would be the possibilities for health and longevity if human beings were brought into life and treated in the natural way from the beginning; that is, from the time
of mating and conception through the prenatal and postnatal periods and on through youth and maturity. Within a few generations the offspring of such Natural heredity would live the full allotted time of a hundred and fifty years in perfect health, strength and beauty, thoroughly efficient in the business of life, a true aristocracy not of vitiated, degenerated blue blood, but of pure red blood of perfect buoyant health.

Many of our young people are now beginning to carry out this great plan for the creation of a better, healthier and more beautiful humanity. They are seeking partners among those who have been educated and trained in the ways of natural living. If the offspring of such naturally mated couples do likewise and select their partners in turn from among those who are the product of natural heredity, what a different humanity will inhabit this earth within a few generations.

This is not vain dreaming. It is marvelous how the youth of this country have taken hold of these new ideas; how many are adopting the new life in harmony with Natural Therapeutic philosophy, physical culture teachings and other Systems of natural living and healing. Quite frequently young couples come to me, saying, "Doctor; we want to get married; but before we do, give us a thorough examination and, if necessary, we intend to take a course of treatment in order to put our bodies in right condition for the great responsibilities of matrimony and procreation."

What wisdom—what a glorious promise of a better; healthier and happier humanity!

**How to Grow Younger**

Keep in the light—cultivate the air and light bath—nothing sweet or beautiful grows or ripens in the darkness.

Avoid fear in all its forms of expression; it is responsible for the greater part of human suffering. The only thing to fear is fear.

Don't live to eat but eat to live. The cook is the chief executioner of King Death.

In the morning do not say, "I am another day older and so much nearer the end"—say "I feel one day younger."

How can we grow old with all eternity before us! The wise men tell us that in the higher life the good ones always appear in the vigor and beauty of mature manhood and womanhood.

What difference makes it if this old suit of ours grows a little shabbier? We shall soon wear a new and better one.

Be as a child, live simply and naturally, steer clear of too much money and too much worry.

Cultivate the spirit of content; nothing ages the face and furrows the brow so quickly as nagging discontent, suspicion
and jealousy.

Before going to sleep, throw off all the cares and anxieties of the day and attune your physical, mental and psychical vibrations to harmonies of rest and peace and love.
